6. *Tragia ramosa* Torr. Stems 12-50 cm. tall, green, erect, decumbent, trailing or sometimes with a tendency to twine; leaves linear-lanceolate to ovate (basal leaves rarely reniform), 1-4 cm. long, 4-20 mm. broad, apically acute, basally truncate to cordate, marginally serrate; racemes with the lowermost 1 (or 2) nodes pistillate, the remaining 2 to 20 nodes staminate; bracts of the pistillate flowers 1.5-2 mm. long, sometimes abaxially

sparingly pubescent; bracts of the staminate flowers subcucullate, 1.2-1.8 mm. long; *staminate flowers*: pedicels 0.7-2 mm. long, the lower persistent part 0.4-1.5 mm. long; calyx lobes 3 or 4 (to 6), 1-2.2 mm. long; stamens (very rarely 2) to 3 or 4 (to 5, as many as 10 in the terminal flowers); filaments thickened and fleshy, 0.3-1 mm. long, connate basally; *pistillate flowers*: pedicels 1-1.5 mm. long, elongating to 2-2.5 mm. in fruit; calyx lobes (5 to) 6 (or 7), 0.8-2.5 mm. long at anthesis, 1.5-3 mm. long in fruit; styles connate for one-third to one-half or more their length; stigmatic surfaces not papillate (except slightly so in aberrant specimens); fruit 3-4 mm. long, 6-8 mm. broad; columella 1.5-2.6 mm. long; seeds 2.5-3.5 mm. long. *T. stylaris* Muell. Arg., *T. nepetifolia* var. *leptophylla* (Torr.) Shinn. Ubiquitous in open areas and disturbed habitats in cen. and s.w. Tex., spring-fall; Mo. and Ark., w. to Calif., Neb. and Colo., s. into Mex.

7. *Tragia amblyodonta* (Muell. Arg.) Pax & K. Hoffm. Stems 12-50 cm. tall, erect to decumbent or trailing; leaves ovate to triangular or hastate, 10-45 mm. long, 8-30 mm. broad, apically acute to obtuse, basally truncate to cordate or hastate, marginally crenate to serrate; racemes with the lowermost 1 (or 2) nodes pistillate, the remaining 3 to 30 nodes staminate; bracts of the pistillate flowers 0.9-1.3 mm. long, abaxially sparsely pubescent; bracts of the staminate flowers subcucullate, 0.9-1.5 mm. long; *staminate flowers*: pedicels 0.7-1 mm. long, the lower persistent part 0.2-0.4 mm. long; calyx lobes 3 or 4 (or 5), 0.9-1.9 mm. long; stamens (very rarely 2) to 3 or 4 (or 5); filaments thickened and fleshy, 0.2-0.7 mm. long, connate basally; *pistillate flowers*: pedicels 0.3-0.4 mm. long, elongating to 1.5-2 mm. in fruit; calyx lobes (5 or) 6, 1-2.3 mm. long at anthesis, 2-3.5 mm. long in fruit; styles connate only at the base or up to one-third their length; stigmatic surfaces papillate; fruit 3-4.5 mm. long, 5.5-8 mm. broad; columella 1.8-2.5 mm. long; seeds 2.6-3.6 mm. long. Rocky open areas usually on limestone in s. Tex. in Starr and Karnes cos., n. to Kent Co. and w. to El Paso Co., spring-fall; Ariz., N.M. and Tex. s. into Mex.

8. *Tragia nigricans* Bush. Stems 15-55 cm. tall, turning black in drying, erect; leaves oblong to oblong-lanceolate, 3-7 cm. long, 10-25 mm. broad, apically acute, basally acute to cuneate, margins deeply dentate; racemes with the single lowermost node pistillate, the remaining 2 to 5 nodes staminate; bracts of the pistillate flowers 2-2.6 mm. long; bracts of the staminate flowers 1-2 mm. long; *staminate flowers*: pedicels 1.3-1.6 mm. long, the lower persistent part 0.2-0.4 mm. long; calyx lobes 3 or 4 (or 5), 1.5-2.5 mm. long; stamens (3) to 4 or 5 (or 6); filaments slender, 0.7-1.3 mm. long, connate for one-third to one-half or more their length; *pistillate flowers*: pedicels 0.7-1 mm. long, elongating to 2-3 mm. in fruit; calyx lobes (5 or) 6, 1-2.3 mm. long at anthesis, 2.4-4 mm. long in fruit; styles connate only at the base; stigmatic surfaces very slightly papillate; fruit 3-3.5 mm. long, 6.5-7 mm. broad; columella 1.7-3.2 mm. long; seeds 2.5-3.2 mm. long. Rocky soil of open woods and fields in Uvalde, Real, Medina, Bandera, Kerr and Comal cos., spring-fall; endemic.

9. *Tragia Smallii* Shinn. Stems 12-25 cm. tall, erect; leaves orbicular to elliptic, 2-4 cm. long, 8-25 mm. broad, apically rounded to acute, basally rounded to obtuse, margins coarsely serrate or crenate to lobed, thick, pubescent, ciliate; racemes with the lowermost 1 (or 2) nodes pistillate, the remaining 4 to 11 nodes staminate; bracts of the pistillate flowers 1.5-2.5 mm. long, sometimes abaxially sparsely pubescent; bracts of the staminate flowers subcucullate, 0.8-1.2 mm. long; *staminate flowers*: pedicels 1.5-1.9 mm. long, the lower persistent part 0.4-0.6 mm. long; calyx lobes 4 or 5 (or 6), 0.9-1.5 mm. long; stamens 2 (very rarely 3); filaments thickened and fleshy, flattened laterally, 0.2-0.5 mm. long, connate basally; *pistillate flowers*: pedicels 0.5-1 mm. long, elongating to 2.8-3.4 mm. in fruit; calyx lobes 6, 1.3-1.7 mm. long at anthesis, 1.5-2.3 mm. long in fruit; styles connate about one-fourth their length; stigmatic surfaces roughened but not papillate; fruit 5-7 mm. long, 9-13 mm. broad; columella 2.2-3.2 mm. long; seeds 4-4.5 mm. long. Dry sandy soil at the edge of woods, in fields and along roadsides in Newton, Jefferson and Hardin cos., spring-fall; Ga. and Fla. w. to e. Tex.

10. *Tragia urens* L. Stems 2-5 dm. tall, erect; leaves broadly oblanceolate to linear, 2-8 cm. long, 2-14 mm. broad, apically acute to rounded, basally acute to attenuate, marginally entire to round-toothed or lobed; racemes with the lowermost 1 (or 2) nodes pistillate, the remaining 3 to 45 nodes staminate; bracts of the pistillate flowers 1-2.5 mm. long, abaxially sparsely pubescent; bracts of the staminate flowers subcucullate, 1-1.5 mm.

long; *staminate flowers*: pedicels 1.3-2 mm. long, the lower persistent part 0.3-0.6 mm. long; calyx lobes 4 or 5, 1-1.5 mm. long; stamens 2 (very rarely 3); filaments thickened and fleshy, 0.2-0.4 mm. long, connate basally; *pistillate flowers*: pedicels 0.6-1 mm. long, elongating to 3.5-4 mm. in fruit; calyx lobes 6, 1-1.5 mm. long at anthesis, 1.5-1.8 mm. long in fruit; styles connate for one-fourth to one-third their length; stigmatic surfaces roughened but not papillate; fruit 3-4 mm. long, 7-8 mm. broad; columella 1.9-2.6 mm. long; seeds 3-4 mm. long. *T. linearifolia* Ell. Sandy soil of open woods and clearings and along roadsides in Shelby, Polk and Hardin cos., spring-fall; Va. s. to Fla. and w. to e. Tex.

13. SEBASTIANIA MUELL. ARG.

A tropical genus of a dozen or so species.

1. *Sebastiania fruticosa* (Bartr.) Fern. SEBASTIAN BUSH. Weak essentially glabrous unarmed shrubs, usually 10-15 dm. tall; leaves alternate; blades elliptic, (2-) 3-7 (-10) cm. long, basally acute to rarely acuminate, marginally entire, apically acuminate, thin, green; petioles (1-) 2-6 (-10) mm. long; stipules lanceolate, brownish, 1-2 mm. long, deciduous; flowers in compact terminal androgynous (but strongly protandrous) spiciform thyrses 2-3 cm. long, each of the minute bractlets of the spike with 2 glandular stipules; *staminate flowers*: calyx cup-shaped, about 0.5 mm. high, 3-lobed more than half the length, yellow-green; petals absent; disk essentially absent; stamens 3, opposite the sepals and only slightly surpassing them; rudiment one; *pistillate flowers*: pedicels about 1 mm. long, (to 6 mm. when in fruit); calyx cup-shaped, of 3 nearly distinct bluntly deltoid fimbriate-erose thin-margined sepals, occasionally in two of the sinuses with two other obsolete minute sepals; petals, disks and glands absent; ovary globose, about 1 mm. high, 3-celled, each cell with a single ovule; styles 3, scorpioid-coiled, simple, the ventral (stigmatic) surface papillate; capsule dry, shallowly tricoccus-globose, about 7 mm. high and 8 mm. thick, dehiscing schizocarpically and loculicidally; columella stout, about 5 mm. long; seed ovoid or plumply ellipsoid, about 5 mm. long, brown-mottled, with a flat platelike caruncle at the upper end, falling at maturity. *S. ligustrina* (Michx.) Muell. Arg. Infrequent in woodlands along streams, e. and s.e. Tex., May; s.e. U.S.

14. SAPIUM P. BR.

A genus of about 100 species in the warmer parts of the world.

1. *Sapium sebiferum* (L.) Roxb. CHINESE TALLOW TREE. Rapid-growing, weedy tree with milky sap, essentially glabrous, unarmed, (2-) 3-10 m. tall, weak-stemmed, with arcuate and often drooping slender branches, the stems and branches brittle; leaves alternate; blades rhombic, 3-7 (-9) cm. long, basally biglandular and rounded to acute, marginally entire, apically acuminate or denticulate; petioles longer than their blades; stipules subulate, caducous; flowers in terminal spiciform androgynous thyrses (3-) 5-15 cm. long, the minute bractlet at each node with two persistent bulbous-glandular stipules; *staminate flowers* in clusters at the upper nodes, each on a pedicel about 1 mm. long, with a cup-shaped irregularly 3-toothed calyx about 1 mm. across; petals, glands and rudiment absent; stamens 2; *pistillate flowers* few, solitary at the nodes; calyx of 3 triangular nearly distinct sepals; petals, glands and disks absent; ovary subglobose, 3-celled, triovulate; styles 3, free and spreading about half the length, entire, the free portion brown, papillate-fungoidal ventrally; fruit 3-coccus, about 1 cm. long, the walls falling readily; seeds 7-8 mm. long, long-persistent on the placenta after the dehiscence of the fruit, chalky-white. Locally abundant near towns, in vacant lots, along rivers, thickets and woods in s.e. Tex., escaped from cult., spring; nat. of Asia, widely introd.

The seeds yield an oil by pressure, and the seed coat yields a whitish wax by boiling.

15. STILLINGIA L.

Glabrous unarmed perennial herbs with milky sap, the shoots from thick erect woody crowns; leaves alternate, ascending, entire, narrow, glandular-serrulate, usually acute,

nearly sessile; stipules of a few subglandular emergences; petioles absent or less than 2 mm. long; flowers in terminal androgynous spiciform thyrses, the minute bract at each node of the inflorescence with 2 glandlike stipules larger than the bract itself; *staminate flowers* on short pedicels, either solitary or clustered at the upper nodes, much-reduced, with a cup-like calyx (only 1-2 mm. long) obscurely, shallowly and unequally 2-lobed; petals and disk absent; stamens 2; *pistillate flowers*: calyx shallowly to deeply 3-lobed with 1 lobe toward (the other 2 away from) the thyrses axis, the lobes 0.7-2 mm. long; petals and disk absent; ovary subglobose, 3-celled, triovulate; styles 3, simple; gynobase (lower part of ovary) after anthesis becoming thick and indurated, persistent; capsules shallowly 3-coccus, 4-12 mm. long, 3-celled, 3-seeded, the upper portion separating from the gynobase and dehiscing loculicidally and septicidally; columella fragile, usually soon broken; seeds 4-8 mm. long not including the caruncle, with a prominent bulbous or semilunate caruncle.

A mainly tropical genus of a couple of dozen species.

1. Staminate flowers solitary at the upper nodes of the spike; leaves 2 to 4 times as long as broad; caruncle of seed half-moon-shaped in ventral view and about 2 mm. across; styles 2 mm. long 3. *S. Treculiana*.
1. Staminate flowers in bracted glomerules of 5 to 15 flowers at each node of the thyrses; leaves 4 to 15 times as long as broad; styles 4-5 mm. long (2)
- 2(1). Leaves (3 or) 4 to 7 (to 10) times as long as broad; capsule about 12 mm. long and broad; caruncle of seed subreniform, about 4-5 mm. across 1. *S. sylvatica*.
2. Leaves 6 to 12 (to 15) times as long as broad; capsule about 6 mm. long and broad; caruncle of seed bulbous and about 1 mm. across ... 2. *S. texana*.

1. *Stillingia sylvatica* L. QUEEN'S DELIGHT. Herb 30-50 (-75) cm. tall; leaf blades narrowly elliptic to lanceolate or oblanceolate, (2-) 3.5-7 (-12) cm. long, (3 or) 4 to 7 (to 10) times as long as broad, apically and basally acute, marginally serrulate or crenulate with a small deciduous gland in each notch; staminate flowers in many-flowered bracted cymules; capsules broadly oblong, distinctly roundly 3-lobed, about 12 mm. long and about as broad, green, very hard and tough; gynobase thick and horny, triangular, each lobe about 6 mm. long; columella about 8 mm. long, triangular with 3 interocular points subterminally, stout but brittle and usually not long persistent, leaving a mere triangular nub on the gynobase; seeds ovate-oblong, 8 mm. long not including caruncle, about 6 mm. broad; caruncle subreniform, about 4-5 mm. across, white, smooth. Frequent in loose sandy soil over most of Tex. e. of the Trans-Pecos, spring-early summer; Va. to Fla., w. to La. and Tex., n. to Kan. and N.M.

2. *Stillingia texana* I. M. Johnst. Herb 2-4 (-6) dm. tall; leaf blades linear or linear-lanceolate, 3-6 (-8) cm. long, 6 to 12 (to 15) times as long as broad, apically and basally acute, marginally serrulate or crenulate and with a minute dark deciduous gland in each notch; staminate flowers in many-flowered bracted cymules; capsules broadly oblong, 3-lobed, about 6 mm. long and about as broad; gynobase thick and horny, triangular, each lobe 3-3.5 mm. long; columella about 5 mm. long, triangular, with 3 subterminal interocular points, stout but brittle and rarely persistent very long after dehiscence; seeds ovate-oblong to elliptic-oblong, about 5 mm. long not including caruncle, about 4 mm. broad; caruncle bulbous, about 1 mm. long and broad. Calcareous uplands of the Edwards Plateau and n.-cen. Tex., w. to Val Verde Co., Apr.-May (June); Okla., Tex. and Coah.

3. *Stillingia Treculiana* (Muell. Arg.) I. M. Johnst. Herb 10-45 cm. tall; leaves sessile, oblong to obovate-oblong, sometimes narrowly so, 1-3.8 cm. long, 6-15 mm. broad, about 2 to 4 times as long as broad, apically rounded to bluntly angled, basally narrowly cuneate or acuminate, marginally coarsely incised-dentate at least toward the apex; staminate flowers solitary at nodes of spike; capsules ovate-oblong, very shallowly 3-lobed, 4.5-5 mm. long, about as broad, pale-green; gynobase triangular, green, fleshy, not at all horny, the acuminate lobes pointed with each about 1.2 mm. long; columella 3.5-4 mm. long, apically enlarged with 3 points and 3 narrow wings, the column very brittle and breaking soon after dehiscence; seeds ovate-oblong, 3.4-3.8 mm. long excluding caruncle,

about 2 mm. broad, strongly narrowed in apical third of length and apiculate; caruncle meniscoid in ventral view, about 1 mm. across, whitish, fleshy, waxy, nearly smooth. Calcareous soils of Rio Grande Plains and Edwards Plateau, n. to Tom Green Co., w. to Crockett and Val Verde cos., local and infrequent, Mar.-June; Tex., Tam., Coah. and N.L.

16. RICINUS L.

A genus of one species.

1. *Ricinus communis* L. CASTOR-BEAN, FIGUERILLA. Coarse mostly glabrous annual (rarely over-wintering in the south) herb, 1-5 m. tall, usually simple-stemmed below and with numerous ascending branches above; internodes hollow, often glaucous; leaves alternate, long-petiolate, peltate, (1-) 2-6 dm. long and broad, with (5 to) 7 to 9 (to 11) deeply serrate palmate lobes; flowers in terminal gynecandrous racemelike inflorescences; sepals 5; *staminate* calyx valvate in bud; petals absent; antheriferous structures about 15 or 20 from the receptacle, each profusely branched and each ultimate branch terminating in an anther; *pistillate* sepals caduous; ovary 3-celled; the 3 styles reddish, subulate, rough, each bifurcate; cells uniovulate; capsule nearly spherical, 12-16 mm. thick, septi-cidal and then loculicidal; seeds ellipsoid, mottled, 8-11 mm. long. Cult. and rarely escaped, more commonly in the s. part of Tex., all year, especially in summer; probably nat. of Afr., now widely distributed in warmer parts of the world.

The seeds are deadly poisonous when ingested, and are the source of castor oil, formerly highly valued as a purgative and machine oil.

17. JATROPHA L.

Perennial herbs or weak low shrubs, essentially glabrous; leaves alternate or fascicled; inflorescences cymose (these so reduced in *J. dioica* that the true form is obliterated); *staminate flowers*: usually the 5 sepals coalescent at least briefly at the base; petals 5, alternate with the sepals, in some species coalescent in the lower part; glands 5, opposite the sepals; stamens (7 or) 8 to 10, in roughly 2 whorls on an androphore, the upper whorl with 5 stamens, the lower with 5 or fewer or the two whorls so close as to appear monadelphous; *pistillate flowers*: sepals 5, often partly coalescent; petals 5, often partly coalescent; bulbous glands 5, opposite the sepals; ovary subglobose, with 1 to 3 cells and 1 to 3 seeds; styles 1 to 3, when 2 or 3 then briefly coalescent basally, usually bifid apically; columella present when the cells are 3; seeds 1, 2 or 3, carunculate.

A primarily tropical genus of perhaps 200 species.

1. Leaves either entire or shallowly lobed or rarely parted into 2 or 3 entire lobes; staminate and pistillate flowers on separate plants; cymes mostly appearing lateral
.....3. *J. dioica*.

1. Leaves palmately 5- to 9-lobed, usually with each lobe serrate or shallowly lobed; staminate and pistillate flowers in the same terminal cyme (2)

2(1). Corolla red; Rio Grande Plains1. *J. cathartica*.

2. Corolla not red; Trans-Pecos grasslands2. *J. macrorhiza*.

1. *Jatropha cathartica* Teran & Berl. JICAMILLA. Perennial herb from enlarged tuber-like woody roots 3-15 (-25) cm. thick and deeply buried; stems usually (5-) 10-30 cm. tall and rather branched and spreading; leaf blades palmately and very deeply 5- to 7-lobed, (3-) 5-10 cm. long, the larger lobes laciniate marginally; petioles as long as or usually longer than the blades; inflorescence open-cymose, bisexual; *staminate flowers* usually the more distal in the cyme, the red corollas 5-8 mm. long; *pistillate flowers* usually lower on the cyme, the corollas red and caducous; styles about 1 mm. long; capsules usually 10-13 mm. long, 3-celled and 3-seeded. *J. Berlandieri* Torr. Scattered in brush on clay soil, Rio Grande Plains, spring-fall; Tex., Tam., N.L. and Coah.

2. *Jatropha macrorhiza* Benth. Perennial herb 3-8 dm. tall; roots fleshy; main stem solitary, stout; leaf blades palmately 3- or 5-lobed more than half their length, often

about 18 cm. long and 15 cm. broad or vice versa, the lobes ovate or lanceolate to oblong-lanceolate and marginally coarsely incised-serrate; *staminate flowers* usually distal in the open cymose inflorescence; calyx less than 1 cm. long; corolla whitish, about twice as long as the calyx; stamens 8 to 10, seemingly monadelphous; *pistillate flowers* nearly like the staminate but usually lower in the cyme; ovary 3-celled, triovulate; styles 3; capsules about 12 mm. long; seeds 9-10 mm. long. Rare (perhaps not persistent) in grama grasslands in Presidio Co. in the Trans-Pecos, collected once, early summer; cen. Mex. n. and n.w. to Ariz. and Tex.

3. *Jatropha dioica* Cerv. SANGRE DE DRAGO, LEATHER STEM, RUBBER-PLANT. Perennial of peculiar habit, scarcely woody (though usually described as a shrub or woody plant); rootstocks buried, orange-colored, horizontal, as much as 1 m. long or longer; stems (which are perennial) thick, fleshy, terete (folded on drying), simple or sparingly branched, rising at intervals, wandlike, 2-6 dm. tall, usually arcuate, with short lateral spurs; sap clear, astringent, on exposure to air turning reddish like blood; leaves fasciculate on the spurs, sessile, deciduous; blades spatulate or linear, widest toward the tip, occasionally palmately 2- or 3-lobed with the middle lobe longest, apically usually blunt, basally narrowed, marginally entire, 4-5 (-7) cm. long; stipules subulate-lanceolate, about 2.5 mm. long, early-deciduous; male and female flowers on separate plants; *staminate flowers* in greatly reduced cymes, appearing to be in dense terminal or axillary fascicles; bracts and sepals more or less scarious, usually entire and nonglandular; calyx 3-3.5 mm. long, silvery-puberulent without; corolla whitish, about half as long as calyx, cylindric-urceolate with recurved lobes, the reddish tube usually longer than lobes and more or less hirsute within at base; stamens regularly 10, the filaments partially united; anthers ovate to linear, often 1 mm. long or less; *pistillate flowers* in reduced often merely 1-flowered cymes; sepals herbaceous; corolla cylindric-urceolate with recurved lobes, the tube usually longer than the lobes and more or less hirsute within at base; locules of ovary and styles 1 or 2, with one ovule in each locule; styles (when 2) coherent to some extent, unequally or irregularly bilobed, the stigmas thickened and fungoid; capsules 1- or 2-locular, each locule 1-1.2 cm. thick and about 15 mm. long (thus when 2-locular the fruit is wider than long); locules apiculate and loculicidal; persistent columella absent; seeds subglobose or somewhat flattened along the ventral line, essentially smooth, brownish; hilum large and flat; caruncle minute and whitish, the rounded dorsal surface with a faint median keel. In scrub in s. and w. Tex.

Represented by two varieties:

Var. *dioica*. Leaf blades 2.5 to 6 times as long as broad, mostly 6-10 mm. wide, rarely lobed. *Mozinna spathulata* Ort. and var. *sessiliflora* Hook. Frequent in Rio Grande Plains n.w. to Val Verde Co. and n. to Bexar, Blanco and Uvalde cos.; Oax. n.w. to Dgo. and Tex.

Var. *graminea* McVaugh. Leaf blades 6 to 17 times as long as broad, mostly 1-4 mm. wide, occasionally parted into 2 or 3 lobes. Frequent in the warmer Chih. Desert of Brewster, Presidio and Jeff Davis cos. in the Trans-Pecos; Zac., Coah., Chih. and Tex.

18. CNIDOSCOLUS POHL

A tropical American genus of perhaps 50 species; rare northward.

1. *Cnidoscolus texanus* (Muell. Arg.) Small. BULL NETTLE, MALA MUJER. Perennial herb (3-) 4-5 (-10) dm. tall and diffuse, as much as 1 m. across, with milky sap and stinging hairs; roots as much as 2 dm. thick and to 1 m. long; stems several from the roots, branching underground and aboveground, 3-5 mm. thick, green, hispid with pale aciculate stinging hairs, the hairs with elongate white bases; leaves alternate; blades suborbicular in outline, 6-15 cm. broad, palmately deeply 3- to 5-lobed and palmately veined with one vein to each lobe, more or less sparsely hispid with pale aciculate stinging hairs especially along the veins; leaf lobes more than half the total length, ovate, acuminate, angulate or sinuate-dentate or again shallowly lobed; petioles a little shorter than to a little longer than their blades, hispid like the stem; petiolar glands inconspicuous at the summit of the petioles on upper surface of blade, brownish-white, papillate or fungoid, forming a mass 2-3 mm. across; stipules inconspicuous, often deciduous, 3-4 mm. long, deeply 3- or 4-toothed or in some plants only one subulate lobe developed,

the others suppressed; male and female flowers in the same cyme; inflorescences terminal (sometimes overtopped by the lateral axillary branches), cymose, pedunculate, much-branched but few-flowered, determinate, the single truly terminal flower pistillate or in some cymes the pistillate flower apparently absent; branches of inflorescence dichotomous toward the distal end, the paired ultimate branches each bearing a staminate flower with 1 to 3 minute subulate bracts subtending each flower; *staminate flowers*: buds 13-19 mm. long, clavellate; the single perianth whorl white, corollalike, showy, fragrant, bearing some aciculate stinging hairs, trumpet-shaped, the subcylindric tube 15-20 mm. long and slightly longer than the 5 (occasionally only 4) subrotate-oblong to spatulate-oblong lobes; stamens 10 (occasionally 9?), all anther-bearing, included in the perianth tube, in two whorls, the inner whorl coherent into a column, the outer whorl distinct to the base and basally villous, a little longer than the perianth tube; *pistillate flowers*: single perianth whorl whitish, 10-17 mm. long, 5-parted essentially to the base; sepals acuminate, not coherent, falling soon after anthesis; ovary oblong or obovate, slightly 3-lobed, 3-celled and triovulate, hirtellous above, very densely hispid with pale-brownish aciculate stinging hairs; styles 3, shortly coherent basally, about 3 times dichotomous, the ends slender; capsules oblong, 15-20 mm. long, hispid; columella prominent, persistent, white, with 3 narrow pectinate-fimbriate wings; seeds 3, oblong, rounded dorsally, very slightly keeled ventrally, 14-18 mm. long, slightly lobed basally, apiculate, surficially smooth, brownish-white; caruncle prominent, sagittate, 3-4 mm. long, yellowish-white. Sandy often disturbed soils nearly throughout Tex., w. to Ward and Crane cos., May-Nov.; La., Okla., Ark., Tex. and Tam.

19. MANIHOT MILL.¹¹⁸

A genus of more than 150 species of the warmer parts of the New World tropics, of which we have only one. The genus is economically important in that *M. esculenta* Crantz (yuca, cassava, mandioca, manioc, etc.) is a root crop grown in most of the world's lowland tropics, and several minor rubber-bearing species are exploited in Brazil. *Janipha* H.B.K.

1. *Manihot Walkerae* Croizat. Perennial herb with very strong odor of HCN in all parts; roots tuberous, carrot-shaped, with large white fleshy storage parenchyma; stems herbaceous, mostly prostrate, dying back to root crown in dry season; leaves alternate, simple, deeply 5-lobed (sometimes 3- or 7-lobed), pandurate to halberd-shaped, the lower 2 smaller lobes of the fully developed vegetative leaves frequently projecting at a sharp angle downward, the median lobe 2-5 cm. long; flowers in androgynous racemes; staminate flowers opening later than pistillate ones, borne in a simple raceme, the pistillate flowers most often on single peduncles arising at base of staminate raceme, the perianth of a single row of tepals; *staminate flowers* tubular, gibbous at base; tepals 6-10 mm. long, united half their length; stamens 6 or 8 in 2 whorls of shorter and longer; slender filaments arising between the lobes of a circular disk; anthers versatile; *pistillate flowers* with 5 separate strap-shaped tepals 5-8 mm. long; stigmas 3, many-branched, on very short styles; ovary 3-locular, inserted above a circular disk; fruit a dry dehiscent capsule; seeds 3, carunculate. Rare on caliche cuestas near the Rio Grande in extreme s. Tex. (Hidalgo Co.), Apr.-Sept., following rains; also Tam.

A vigorous colony has been transplanted to the campus of The University of Texas at Austin on the south side of Biology Laboratories. Nearest relative is *M. angustiloba* (Torr.) Muell. Arg. from which it differs in broader leaf lobes, numbers of stamens (10 in *M. angustiloba*), in distribution and habitat.

20. EUPHORBIA L. SPURGE

Herbs with milky sap, very diverse in vestiture, phyllotaxy and branching; flowers borne in bisexual groups, the pedicels either included in or exerted from small cup-shaped or urn-shaped calyxlike involucre (the individual bracts of which are not discern-

¹¹⁸ Contributed by David J. Rogers.

ible except as lobes at the rim), often with one or more glands attached to the top of the involucre between the lobes and near the rim, the glands often furnished with "horns" (i.e., pointed appendages, one at each end of the gland) or petaloid appendages; *staminate flowers* each consisting of a single naked stamen, few to many in groups or cymules within the involucre; *pistillate flower* solitary, central in each cyathium and often long-exserted from it, lacking a recognizable perianth, with a 3-celled 3-ovulate ovary; styles 3, each usually bifid; seeds 3, one in each cell. *Tithymalus* Trew; *Poinsettia* Grah.; *Agaloma* Raf.; *Chamaesyce* S. F. Gray.

An enormous genus with species in all the tropical and temperate parts of the world. The genus is reputed to be difficult taxonomically but our species offer no great problems of determination. Complete specimens, with roots and mature seeds, can easily be determined.

1. Glands of the involucre without petaloid appendages (some species with hornlike appendages on the glands); leaves alternate or opposite; leaf blades (at least those of the main stem) essentially bilaterally symmetrical (subg. *Poinsettia* and *Esula*) (2)
1. Glands of the involucre with petaloid appendages (in one species these several and folded over the gland), OR if appendages absent then leaves all strictly opposite and with inequilateral bases (blades then not bilaterally symmetrical) (subg. *Agaloma* and *Chamaesyce*) (13)
- 2(1). Involucral glands flat or convex; leaves mostly alternate on the main stem or (if opposite) decussate, also forming a single whorl just beneath the inflorescence which is an umbelliform cyme (pleiochasium), also opposite above at the pseudo-dichotomies of the branches of the pleiochasium; glands 4 or 5 per cyathium (subg. *Esula*) (3)
2. Involucral glands deeply cupped; stems never branched into a symmetrical 3- to several-rayed inflorescence; glands only 1 to 3 per cyathium (subg. *Poinsettia*) (10)
- 3(2). Glands of the involucre with rotund and entire margins (4)
3. Glands of the involucre either with a horn at each end or semilunate with the concave side and the points outward (5)
- 4(3). Main branches of the main pleiochasium 5; capsules never warty 8. *E. Helioscopia*.
4. Main branches of the main pleiochasium 3; capsules usually warty (smooth in one rare form) 7. *E. spathulata*.
- 5(3). Seeds quite completely smooth, whitish, ovoid 2. *E. Helleri*.
5. Seeds with pits or depressions (or if minutely tuberculate see *E. exigua* under *E. Peplidion*) (6)
- 6(5). Pits of seeds in regular rows (at least on the 2 ventral facets) or with a single long vertical pit on each ventral facet (7)
6. Pits of seeds irregularly disposed, at least nowhere in distinct vertical rows (8)
- 7(6). Each ventral facet of the seed with a single long depression 3. *E. Peplidion*.
7. Each ventral facet of the seed with a vertical row of smaller pits 4. *E. tetrapora*.
- 8(6). Strong perennial; west Texas east to Edwards Plateau 1. *E. brachycera*.
8. Slenderly taprooted annuals (9)
- 9(8). Seeds with small deep pits; opposite leaves of the pleiochasial branches only very slightly connate basally 5. *E. longicuris*.
9. Seeds with broad pits and ridges between; opposite leaves of the pleiochasial branches connate to the middle 6. *E. Roemeriana*.

- 10(2). Rather humble perennial from tuberous roots; stems several; cyathia in compact terminal cymes subtended by discolored floral leaves, the flowering stems otherwise bearing only bractlike leaves, the leafy shoots appearing in summer after the vernal flowering; capsules usually longer than 5 mm. 21. *E. radians*.
10. Stems solitary from annual taproots; shoots not dimorphic; capsules shorter than 5 mm. (11)
- 11(10). Leaves mostly opposite; seeds mostly 2.6-2.8 (-3.1) mm. long 22. *E. dentata*.
11. Leaves alternate between the first or second pair of leaves and those at the top of the plant; seeds mostly (2.7-) 3-3.5 mm. long (12)
- 12(11). Gland and its opening (depression) at top oblong, about 1 mm. long, shallowly bilabiate; seeds not strongly angular in transection .. 23. *E. cyathophora*.
12. Gland and its opening (depression) on top circular, much less than 1 mm. long, not bilabiate; seeds in transection showing a dorsal keel and 2 lateral angles 24. *E. heterophylla*.
- 13(1). Robust annual herbs to 1 m. tall, with single main stem and a few short pseudodichotomous branches at top; leaves alternate, the uppermost (near the flowers) with thin white margins (14)
13. Plants various, usually much less than 1 m. tall; leaves in most species opposite, never white-margined (15)
- 14(13). The white-margined bracteal leaves at top of plant narrowly lanceolate 12. *E. marginata*.
14. White-margined bracteal leaves at top of plant linear .. 13. *E. bicolor*.
- 15(13). Strongly perennial plants, caespitose, with numerous essentially leafless glaucous fleshy branches 2-5 (-10) dm. long and 2-4 mm. thick rising erect from the woody horizontal primary stems 9. *E. antisiphilitica*.
15. Plants various, when many-branched from a woody base then the branches comparatively slender and/or leafy; leaves in most species opposite (16)
- 16(15). Stipules glandlike or obsolete; leaf blades symmetrical; branching at the top of the plant usually pseudodichotomous, with cyathia borne in the forks (17)
16. Stipules well-developed for the most part (at least on one side of the stem) or if stipules poorly developed then blades asymmetrical and their bases inequilateral (subg. *Chamaesyce*) (27)
- 17(16). Appendages 2 or several per gland (actually solitary and deeply parted to the base); erect nearly glabrous annual herbs with subentire linear leaves (18)
17. Appendages solitary per gland, if deeply lobed then the leaves serrulate (19)
- 18(17). Glands more than 3 per cyathium (usually 5); appendages 2 per gland (solitary and deeply bifid); main stem 0.5-2.5 mm. thick ... 17. *E. bilobata*.
18. Glands usually only 3 per cyathium; appendages 5 to 7 per gland, linear, hairy, folded upward and inward covering the gland; main stem 3-12 mm. thick 18. *E. eriantha*.
- 19(17). Leaf blades ovate, the margins serrulate to the rounded or truncate base; petioles nearly as long as blades; slender erect annual herb 14. *E. bifurcata*.
19. Leaf blades linear to linear-lanceolate OR if ovate then much longer than the petioles (20)
- 20(19). Taprooted annual herbs, single-stemmed from the base (21)
20. Perennials, usually with more than one stem at ground level (22)

- 21(20). Plant usually not more than 2 dm. tall; leaves usually manifestly serrate; seeds 2.2-2.9 mm. long, with 2 broad tuberculate transverse ridges and a slight widening at the narrow apical end, with rounded protuberances at the intersections of the ridges and longitudinal angles15. *E. exstipulata*.
21. Plant usually 3-10 dm. tall; leaves usually not manifestly serrate; seeds ovoid, not angular, about 3 mm. long, with low bumps scattered all over the surface
.....16. *E. hexagona*.
- 22(20). Leaves about as broad as long to twice as long as broad, blunt; stems usually prostrate on coastal sands20. *E. innocua*.
22. Leaves more than twice as long as broad; stems mostly ascending (23)
- 23(22). Stems (at least the younger parts) usually densely white-pubescent; leaf blades ovate, widest near the base, sharp-pointed, mostly less than 5 times as long as broad; plants mostly less than 2 dm. tall; petaloid appendages usually present and often crenate25. *E. acuta*.
23. Stems if pubescent minutely so; character combination otherwise differing (24)
- 24(23). Seed 2.3-2.5 mm. long; appendages of glands 1.5-4 mm. long, much longer than the gland is broad; plants usually in sandy soils of eastern half of Texas
.....19. *E. corollata*.
24. Plants not with above combination of characters, mostly of calcareous or sandy uplands of western half of Texas (25)
- 25(24). Spring (lowermost) leaves deciduous but when present oblong and shorter and much broader than summer leaves that are linear; perennial underground parts mostly less than 5 mm. thick; involucre sessile or the peduncles rarely more than 3 mm. long26. *E. angusta*.
25. Spring and summer leaves linear or linear-filiform; perennial underground parts usually more than 5 mm. thick; peduncles slender, 3-8 mm. long or longer (26)
- 26(25). Opposite or whorled leaves at top of plant longer than the subtended peduncles10. *E. Wrightii*.
26. Opposite or whorled leaves at top of plant shorter than the subtended peduncles ...
.....11. *E. strictior*.
- 27(16). The 3 styles very short (about 0.5 mm.) and abruptly and thickly round-capitate, not bifid; low perennials, all glabrous; stipules united into short scales (28)
27. The 3 styles bifid OR if appearing entire then not abruptly thickly round-capitate; plants various in habit and pubescence (29)
- 28(27). Appendages forming a narrow entire margin on the gland; leaves often appearing clasping; plants glaucous or grayish-green49. *E. astyla*.
28. Appendage deeply dissected and lobed; leaves short-petiolate; plants drying dull-greenish or brownish48. *E. jejuna*.
- 29(27). Appendages deeply parted, lobed or dissected at least halfway to the gland (30)
29. Appendages entire, lacerate, undulate or crenulate but not parted more than halfway to the gland OR appendages absent (31)
- 30(29). Glabrous perennial; each of the 4 appendages parted to the base into 3 or 4 (to 6) narrow linear segments47. *E. Fendleri* var. *triligulata*.
30. Plants short-lived (probably annual); herbage and capsules shaggy or villous; each of the 4 appendages parted into 3 to 5 narrow attenuate lobes
.....53. *E. setiloba*.
- 31(29). Appendages markedly unequal on each involucre, the 2 nearest the ovary at least twice (usually 3 to 5 times) as long as the other 2 appendages; prostrate annual57. *E. indivisa*.
31. Appendages subequal or absent (32)

- 32(31). On each side of the stem the 2 stipules at each node united into a white or reddish-white membranous glabrous scale which may be either entire or lacerate; plants commonly rooted at the lower nodes (33)
32. Stipules otherwise or if seeming united into a scale then only so on one side of the stem OR the entire structure deeply lobed or dissected; plants only rarely rooted at the lower nodes (34)
- 33(32). Annual; staminate flowers fewer than 12 per involucre51. *E. serpens*.
33. Perennial; staminate flowers more than 12 per involucre50. *E. albomarginata*.
- 34(32). Plants essentially glabrous, including the herbage, inflorescence, ovaries and capsules (sometimes the stipules ciliate or the inside of the involucre may be beset with hairs) (35)
34. Plants with some pubescence on herbage or inflorescence or both (52)
- 35(34). Leaves linear, more than 6 times as long as broad; plants annual; leaf margins entire (36)
35. Leaves not linear OR if narrow then serrulate OR less than 6 times as long as broad; plants various (38)
- 36(35). Capsules shorter than 1.7 mm.; delicate erect annual, the stems mostly less than 1 mm. thick and the plants less than 2 dm. tall; seeds with 1 to 3 transverse ridges33. *E. revoluta*.
36. Capsules longer than 1.8 mm.; stems rather robust, often at least 1 mm. thick; seeds plump and smooth (37)
- 37(36). Petaloid appendages forming narrow margins on the glands and usually more or less ascending; stems usually spreading, prostrate .31. *E. Parryi*.
37. Petaloid appendages mostly longer than the glands are wide, ovate, conspicuous, more or less spreading; stems usually erect or ascending32. *E. missurica*.
- 38(35). Capsules longer than 2.8 mm. (mostly 3 or 5 mm. long); plants robust; larger leaves usually longer than 1 cm.; leaf margins entire (39)
38. Capsules shorter than 2.8 mm. long (usually much shorter); most leaves shorter than 1 cm. OR if most leaves longer than 1 cm. then the margins serrate or serrulate (40)
- 39(38). Strong perennial; stems apparently not prostrate; leaves usually about 1 cm. long with blunt apices; capsules about 3 mm. long at maturity; seeds not laterally compressed46. *E. perennans*.
39. Robust annual with spreading prostrate stems; leaves usually about 15 mm. long and pointed; capsules about 5 mm. long at maturity; seeds laterally compressed28. *E. carunculata*.
- 40(38). Leaves mostly serrate or serrulate at least toward the apex; annuals (41)
40. Leaves entire as seen under a lens (45)
- 41(40). Capsules about 1.3 mm. long; cyathia densely glomerulate; erect or ascending herbs of extreme south Texas36. *E. hypericifolia*.
41. Capsules mostly longer or if approaching as short as 1.4 mm. long then cyathia not glomerulate (42)
- 42(41). Erect annuals, comparatively robust, with most mature leaves more than 15 mm. long; capsules 1.6-2.3 mm. long, mostly more than 1.8 mm. long (43)
42. Usually prostrate or decumbent annuals with most mature leaves less than 15 mm. long; capsules 1.4-1.9 mm. long, mostly less than 1.8 mm. long (44)
- 43(42). Seeds finely wrinkled35. *E. nutans*.
43. Seeds with 2 or 3 broad very shallow depressions separated by low smooth transverse ridges34. *E. hyssoipifolia*.

- 44(42). Seeds sometimes with shallow transverse rugae but these faint; stems (at least toward the tips) often "winged" (flattened somewhat in the plane of the leaves); staminate flowers more than 5 per involucre40. *E. serpyllifolia*.
44. Seeds with definite transverse ridges or corrugated; stems not noticeably flattened; staminate flowers usually about 4 or 5 per involucre41. *E. glyptosperma*.
- 45(40). Seeds with 3 or 4 strong transverse ridges; appendages small or absent; capsules 1.2-1.5 mm. long; stems not flattened toward the tips; plants annual; staminate flowers more than 20 per involucre42. *E. theriaca*.
45. Seeds smooth or wrinkled but without ridges (46)
- 46(45). Capsules shorter than 1.7 mm.; glands without appendages or with but very small ones; seeds shorter than 1.3 mm. (47)
46. Capsules longer than 1.7 mm. OR if shorter then appendages developed; seeds longer than 1.3 mm. (48)
- 47(46). Perennial (or at least often becoming ligneous at base by the end of the winter); staminate flowers more than 10 per involucre45. *E. stimulans*.
47. Annual; staminate flowers fewer than 10 per involucre, usually only 2 to 544. *E. micromera*.
- 48(46). Seeds smooth and plump (49)
48. Seeds often wrinkled or if smooth then slender, not plump (50)
- 49(48). Leaf blades about 3 times as long as broad; style branches usually slightly thicker than the united portion; plants of Coastal Plain within 100 miles of the coast29. *E. ammannioides*.
49. Leaf blades usually about twice as long as broad; style branches about as thick as the united portion; distributed farther inland, rare within 100 miles of the coast ..30. *E. Geyeri*.
- 50(48). Stipules parted into numerous filiform segments; sands of east and southeast Texas52. *E. cordifolia*.
50. Stipules mostly linear; dry uplands of central and west Texas (51)
- 51(50). Taprooted annual; leaves apically rounded; petioles 1-2 mm. long43. *E. Golondrina*.
51. Perennial herb; leaves apically acute; petioles 0.5-1 mm. long47. *E. Fendleri*.
- 52(34). Ovary and capsule glabrous (53)
52. Ovary and capsule not glabrous (58)
- 53(52). Robust erect annuals with serrate leaves; most mature leaves longer than 15 mm.; capsules 1.6-2.3 mm. long, most of them more than 1.8 mm.; seeds with wrinkles or low ridges (54)
53. Comparatively humble annuals or perennials; leaves various but all shorter than 15 mm.; capsules mostly shorter than 1.8 mm. or if longer then the seeds usually smooth (55)
- 54(53). Stems usually crisply hairy at least toward the tips, rarely pilose; seeds finely wrinkled35. *E. nutans*.
54. Stems pilose (sometimes sparingly so); seeds with broad very shallow depressions separated by low smooth ridges34. *E. hyssopifolia*.
- 55(53). Annual or perennial, usually erect; stems pilose; capsules deeply 3-lobed, 1.3-1.9 mm. long; leaf margins entire to coarsely serrate; seeds smooth or faintly wrinkled, not transversely ridged55. *E. villifera*.
55. Annuals; stems usually decumbent or prostrate; capsules not deeply 3-lobed but merely tricocous, usually triangular in transection (56)
- 56(55). Stems pilose; leaf margins sharply serrulate; capsules longer than 2 mm.; seeds quite smooth, sharply angled, pale-brownish to chalky-white56. *E. serrula*.
56. Pubescence of stems (if any) short; capsules shorter than 2 mm.; staminate flowers usually only 5 per cyathium (57)

- 57(56). Capsules about 1.3 mm. long, all shorter than 1.6 mm.; leaf margins entire; seeds smooth or faintly wrinkled44. *E. micromera*.
57. Capsules 1.4-1.7 mm. long; leaf margins serrulate at least toward the apex; seeds transversely ridged (here will key out unusual individuals of this species of usually glabrous plants)41. *E. glyptosperma*.
- 58(52). Capsules 2.8-3.1 mm. long; strong perennial, erect or ascending, mostly less than 2 dm. tall; leaves ovate or ovate-lanceolate, widest near the base, 1-2 cm. long, sharp-pointed, the margins entire; appendages usually developed and usually distinctly crenate25. *E. acuta*.
58. Capsules shorter than 2.6 mm. OR if about 2.6 mm. long then plants not as above (59)
- 59(58). Perennial, erect; spring (lowermost) leaves when still present oblong, shorter and broader than summer leaves that are linear, at least 6 or 7 times as long as broad, the margins entire; capsules 2-2.6 mm. long; appendages usually developed26. *E. angusta*.
59. Plants various; leaves not linear OR if almost so then capsule almost 2.5 mm. long (60)
- 60(59). Perennial by slender rootstocks; shoots ascending or erect, mostly less than 2 dm. tall; spring leaves broader than summer leaves; blades ovate-deltoid-falcate to long-deltoid or virtually linear by revolution of the entire margins, shorter than 12 mm., blunt; capsules 1.9-2.3 mm. long27. *E. lata*.
60. Plant various; capsules 2 mm. long or shorter (61)
- 61(60). Perennial, the stems prostrate or ascending; involucre borne in dense cymose glomerules or a few of them in addition sometimes solitary in the upper forks; leaves relatively large, 7-15 mm. long, the margins sometimes with a few teeth; capsules 1.3-2 mm. long; appendages usually developed; Trans-Pecos plants38. *E. pycnanthema*.
61. Plants not having the above combination of characters (62)
- 62(61). Ascending taprooted annual; cyathia very small and numerous, borne in very dense essentially leafless stalked glomerules from upper axils of the usually rhombic leaves; rare weed of southern coastal Texas37. *E. hirta*.
62. Plants not with the above combination of characters (63)
- 63(62). Pubescence of stems and capsule short, not shaggy or villous; leaf margins entire; appendages small or absent; facets of seeds essentially smooth, at least without transverse rugae (64)
63. Pubescence of stems shaggy or villous or pilose and that of the capsules somewhat similar (65)
- 64(63). Perennial; stems rather densely clothed with crisped short mostly appressed hairs; lower surfaces of leaves often closely tomentose; entire plant taking on to some extent the grayish color of the vestiture39. *E. cinerascens*.
64. Annual; pubescence short and sparse44. *E. micromera*.
- 65(63). Perennial; stems villous or pilose, the hairs appearing clavellate or glandular at times under a lens; leaf margins entire; appendages usually well-developed; capsules about 1.5 mm. long; involucre narrowly urceolate54. *E. arizonica*.
65. Annuals; stems usually prostrate and "shaggy" pubescent or villous; leaf margins usually serrate or serrulate; appendages present but often very small; involucre obconical (66)
- 66(65). Seeds punctately pitted and mottled, the base depressed-truncate, the apex sharply acute; styles entire (sometimes emarginate)60. *E. stictospora*.
66. Seeds neither punctately pitted nor mottled, the base obtuse, the apex not sharply acute; styles bifid at least briefly (67)

- 67(66). Seeds with low rounded transverse ridges not whitened on the summit or with merely granular surfaces; capsules strigose (68)
67. Seeds with narrow sharp transverse ridges or rounded transverse ridges whitened on the summit; capsules tomentose or with crisped spreading hairs (69)
- 68(67). Styles about 0.3 (-0.4) mm. long, clavate; nodes never rooting 58. *E. maculata*.
68. Styles 0.5-0.7 mm. long, slender; nodes often rooting .. 59. *E. humistrata*.
- 69(67). Herbage grayish-pilose-tomentose; seeds 1.1-1.3 mm. long, the rounded ridges about the same width as the intervening valleys 62. *E. laredana*.
69. Herbage green or greenish, less densely pubescent to subglabrous; seeds 0.9-1 mm. long, the minute sharp ridges narrower than the intervening valleys 61. *E. prostrata*.

1. *Euphorbia brachycera* Engelm. Mostly glabrous perennial herb 1-6 dm. tall; main stems 6 to many from the woody crown, 1-2.5 mm. thick, erect, 7-45 cm. long; branches mostly from the upper half of main stems; main stems and branches each topped by a whorl of 3 branches (forming a pleiochasium) that are repeatedly pseudodichotomous, divergent, forming the upper sixth to third of the plant; leaves of the stems and branches alternate, at the bases of the pleiochasia whorled, at the forks of the pleiochasia opposite; alternate leaf blades elliptic-oblong to lanceolate or oblanceolate to even obovate, 5-20 mm. long, (2 or) 3 to 4 (or 5) times as long as broad, at apex usually acute, at base attenuate or rounded, marginally entire, with petioles less than 1 mm. long; whorled leaves with rhombic-deltoid to ovate blades 5-15 mm. long, at apex acute, marginally entire, with petioles less than 1 mm. long; opposite leaves rhombic-deltoid, at base truncate or broadly rounded, at apex acute, marginally entire, essentially sessile; stipules absent; cyathia solitary in the forks of the pleiochasia; peduncles shorter than 1 mm.; involucre turbinate to slightly campanulate, 1-2 mm. long to base of glands; glands 4, stalked, yellow, glabrous, about 0.5 mm. long, the ends protruding outward as short horns, the margin between the horns entire or dentate; appendages absent; *staminate flowers* several per cyathium; *pistillate flower*: gynophore well-exserted from the involucre, recurved at maturity; styles 3, erect, bifid half their length, about 1 mm. long, the stigmas clavate or subcapitate; capsule 2-3 mm. long, 3-lobed or often 1- or 2-lobed by abortion, smooth; columella about 2.1 mm. long; seed smoothly round-ovoid, 1.8-2.6 mm. long, grayish with irregular fuscous shallow pitting throughout except on the ventral micropylar beveled caruncular surface; caruncle about 0.5 mm. long, rounded-conic. Incl. *E. montana* Engelm. var. *gracillior* Engelm. and var. *trifaris* Nort., *E. odontadenia* Boiss., *Tithymalus brachycerus* (Engelm.) Small. Frequent in Trans-Pecos mts. at elev. of 4,500 to 7,000 ft. and infrequent or rare near creeks in the Edwards Plateau, Mar.-July; Colo., N.M., Ut., Ariz., Tex. and Chih.

2. *Euphorbia Helleri* Millsp. Taprooted glabrous annual (5-) 10-30 cm. tall; stems several (rarely solitary) from ground level, ascending, with few ascending alternate branches about equaling the main stem, at the base of the pleiochasium pseudotrichotomous (rarely pseudodichotomous) above which all the branching is sparse and pseudodichotomous; leaves of main stem alternate, spatulate, 6-15 mm. long, 3-5 mm. broad, obtuse or retuse, narrowed basally, the lowest ones with petioles 1-3 mm. long; leaves at base of pleiochasium in a whorl of 3 (rarely opposite), oblong or cuneate-oblong; leaves of the branches opposite, orbicular-ovate to nearly reniform, subpandurate, unequal, obtuse, mucronate, broadly cuneate to truncate basally, 3-8 mm. long, 5-10 mm. broad; stipules absent or minute and glandlike; cyathia solitary in the upper forks; involucre about 1 mm. long, the incurved lobes ovate, truncate and ciliate; glands 4, transversely elliptical, about twice as long as broad, at each end with a small whitish curved horn about half as long as the body of the gland, other appendages absent; *staminate flowers* about 10 per cyathium; *pistillate flowers*: ovary well-exserted; styles 3, bifid, the branches clavellate; capsule depressed-globose, 2.5 mm. long, 3 mm. broad, tricocous; seeds ovoid, whitish, quite smooth, 1.4-1.6 mm. long, 1-1.2 mm. broad and thick; caruncle thin but raised into a cone at the center. *Tithymalus Helleri* (Millsp.) Small. Rare and local in clay loam or calcareous soil, coastal s. Tex., Nueces and Cameron cos., Feb.-Mar.; also N.L.

3. *Euphorbia Peplidion* Engelm. Glabrous annual herb 5-20 cm. tall; stems 1 to several from the base, 1-2 mm. thick, erect, (3-) 6-10 (-14) cm. long; branches few, alternate, more slender than main stem, erect, attaining nearly the same height as main stem; main stem and branches each topped by a whorl of 3 (or 4, rarely 5) branches (forming a pleiochasium) which are repeatedly pseudodichotomously branched, divergent and forming the upper third of the plant; leaves of the stem and branches alternate, whorled at the bases of the pleiochasia, opposite at the nodes of the pleiochasial branches, all sessile; blades of stem- and branch-leaves linear-oblongate or narrowly spatulate, 5-20 mm. long, 1-4 mm. wide, at apex rounded, at base attenuate, marginally entire, without stipules; whorled leaves narrowly rhombic-lanceolate, 8-15 mm. long, rounded apically and basally; opposite leaves narrowly deltoid-lanceolate, asymmetrically falcate, 6-10 mm. long, acute at apex, marginally entire or somewhat erose, without stipules; cyathia solitary in the forks of the pleiochasia; peduncles short; involucre broadly turbinate or usually campanulate, 0.6-0.9 mm. long to base of glands, whitish; glands 4, short-stalked, oblong with a long white erect horn at each end, marginally smooth, 0.5 mm. long, 0.2 mm. wide, other appendages absent; *staminate flowers* 5 to 10 per cyathium; *pistillate flower*: gynophore about 2 to 3 times as long as the involucre at maturity, erect or usually curved; styles 3, 0.5 mm. long, bifid nearly to the base, erect or spreading; stigmas capitellate; capsule depressed, deeply 3-lobed, 2-2.3 mm. long, about 3 mm. broad, smooth, the lobes rounded or flattened or rarely even slightly round-keeled; columella 1.7-1.9 mm. long; seed oblong, 1.6-1.9 mm. long, 0.9 mm. thick, subhexagonal, brownish, the angles rounded, with 4 or 5 vertical rows of pits or depressions visible from the dorsum (2 or 3 pits per row) and the 2 ventral facets each with a single vertically elongate pit or depression; caruncle situated on a ventral micropylar beveled surface, flat, umbonate, bilobed, vesicular, rather small. *Tithymalus Peplidion* (Engelm.) Small. Calcareous soil, rare and local, in Trans-Pecos (Pecos Co.), Edwards Plateau (Tom Green, Uvalde and Val Verde cos.) and Rio Grande Plains (Jim Wells and Duval cos.), spring; endemic.

Plants with a rather similar superficial appearance to *E. Peplidion* but with seeds tuberculate all over are *E. exigua* L., collected once in Nueces Co. (adventive from Old World); probably not a persistent member of our flora.

4. *Euphorbia tetrapora* Engelm. Delicate taprooted annual 7-20 cm. tall; main stem solitary or 2 or 3 from the base, usually nearly simple below the pleiochasium, with internodes a half to a third as long as the leaves; pleiochasium trichotomous at the base, the 3 branches 1-8 cm. long, several times dichotomous when longer than 2 cm.; stem leaves alternate, cuneate-spatulate, apically retuse or obcordate, the lower ones 3 mm. long and 1 mm. broad and with short petioles, the higher ones about 1 cm. long and 5 mm. broad and nearly sessile; leaves at base of pleiochasium in a whorl of three, more obovate than the stem leaves; leaves of branches opposite, triangular-ovate, mucronate, truncate or cordate at the base, basally subconnate, 3-6 (-10) mm. long, 5-8 (-14) mm. broad; stipules absent or minute and glandlike; cyathia solitary in the upper forks; involucre about 1 mm. high and broad; lobes ovate, shortly ciliate; glands 4, about 1 mm. long and 0.5 mm. broad, transversely oblong, short-stipitate, on each end with a slender horn 1 mm. long and diverging or usually erect, other appendages absent; *staminate flowers* 10 to 15 per cyathium; *pistillate flowers*: ovary long-exserted; styles 3, 0.5-1 mm. long, united at base, short-bifid apically, the branches capitellate; capsule subglobose, about 2.5 mm. thick, roundly tricocous; seeds oblong, slightly dorsiventrally flattened, 1.3-1.4 mm. long, 0.8-0.9 mm. broad, 0.7 mm. thick, each of the 2 inner facets with 4 to 6 shallow pits or these rarely confluent into irregular oblong grooves, the dorsum with 15 to 20 irregularly arranged shallow pits or almost smooth; caruncle with a dome-shaped umbo in the center. *Tithymalus tetraporus* (Engelm.) Small. Local in sandy soils, e. and n.-cen. Tex., rare in Llano region of Edwards Plateau, spring; Ga., Ala., La., Ark., Okla. and Tex.

5. *Euphorbia longicruris* Scheele. Taprooted delicate annual 5-20 (-25) cm. tall; main stem simple below the pleiochasium with internodes 2-6 mm. long, giving way upward to a trichotomy and above that the 3 branches 1-3 cm. long and repeatedly dichotomous with very short internodes; stem leaves alternate, cuneate-spatulate below to obovate above, 5-15 mm. long, 2-6 mm. broad, at apex mucronate, obtuse to retuse, at

base narrowed, marginally entire, the very short petioles present only on the lowest leaves and stipules absent or minute and glandlike; leaves of pleiochasium whorled at base, opposite on branches, overlapping, reniform or suborbicular, 4-7 mm. long, 7-13 mm. broad, slightly connate and very inequilateral basally; cyathia solitary in the forks of the pleiochasium; involucre 1.5-2 mm. long, 1-1.5 mm. thick, its lobes oblong, minutely ciliate; glands 4, crescent-shaped, on each end with an erect rarely lobed horn twice as long as the body is broad; appendages absent; *staminate flowers* 10 to 15 per cyathium; *pistillate flower*: styles 3, about 0.5 mm. long, bifid; capsule, ovoid-spherical, depressed basally, about 2.5 mm. long, 2.5-3 mm. thick; seeds oblong in outline, slightly dorsiventrally flattened, about 1.5 mm. long and 1 mm. broad and thick, with a slightly dorsal ridge and a prominent projection from the chalaza and surficially with numerous pits the diameter of which is less than half the width of the space between them; caruncle small, depressed-conical, umbonate. *Tithymalus longicruris* (Scheele) Small. Infrequent and local in calcareous soil, Edwards Plateau, n.-cen. Tex. and e. part of Plains Country, spring; Tex., Okla. and N.L.

6. *Euphorbia Roemeriana* Scheele. Taprooted annual 1-3 dm. tall; main stem 1 or few, erect (in shade forms weak and basally decumbent), sparingly branched below the pleiochasium; internodes much shorter than the leaves; pleiochasium trichotomous basally, each branch 1 to 4 times dichotomous and with internodes 2-10 mm. long; leaves of main stems alternate, the blades cuneate, the lower ones obtuse apically and 3-10 mm. long and 1-5 mm. broad with petioles 1-6 mm. long, the upper ones to 2 cm. long and 1 cm. broad and nearly sessile; leaves at base of pleiochasium whorled, ovate to oblong, very obtuse, 1-2 cm. long or longer, 5-10 mm. broad or more; leaves of the pleiochasial branches opposite, semicircular, connate to the middle, 1-2 cm. broad, 7-10 mm. long; cyathia solitary in the upper forks; involucre campanulate, 1.5-2 mm. high, its lobes broadly oblong and minutely ciliate; glands 1 mm. long and broad including the horns, at each end with a slender horn shorter than the width of the body, usually incurved; appendages absent; *staminate flowers* about 10 per cyathium; *pistillate flowers*: ovary long-exserted; styles 1.5 mm. long, bifid a third to a fourth the length; capsule subglobose, about 3 mm. thick; seeds oblong-ovoid, somewhat dorsiventrally flattened, 1.6-1.8 mm. long, 1.4-1.5 mm. broad, about 0.9 mm. thick, rather deeply and broadly pitted, the chalazal projection prominent; caruncle small, low, conical, umbonate. *Tithymalus Roemerianus* (Scheele) Small. Locally abundant in rich calcareous soil, creek canyons, e. part of Edwards Plateau, spring; endemic.

This is the southern counterpart of *E. commutata* Engelm. and probably should be considered merely a race of it; reports of the occurrence of *E. commutata* in Texas have been based on specimens of *E. Roemeriana*.

7. *Euphorbia spathulata* Lam. Glabrous annual herb 5-40 cm. tall; main stems 1 to 3 (or 4 or 5) from the base, rarely as many as 10, 1-4 mm. thick, erect, 5-30 cm. long; branches few basally, many in the upper half, alternate, more slender than the main stems, ascending to erect, attaining about the same height as the main stems; stems and branches of the pleiochasium 3 in a whorl, repeatedly pseudodichotomous, several cm. long (very variable and apparently indeterminate); leaves alternate on stems and branches except opposite at the forks of the pleiochasia and whorled at the bases of the pleiochasia, all sessile; leaf blades of stems and branches obovate-oblong, widest above the middle, rounded at both ends or tapering to the base, obtuse to emarginate at apex, 10-25 mm. long, 5-10 mm. broad, marginally serrulate at least on the upper half, with stipules apparently absent; leaf blades of the pleiochasial branches broadly elliptical to ovate, rounded at the base and rounded or acute at apex, usually serrulate toward the apex, 3-9 mm. long, with no stipules; cyathia solitary and sessile in the forks of the pleiochasia; involucre narrowly turbinate, about 1 mm. long or less; glands usually 4, sessile, glabrous, minute, elliptical; appendages and horns absent; *staminate flowers* several per cyathium; *pistillate flower*: gynophore not exserted, erect at maturity; ovary warty at summit; styles 3, bifid nearly to the middle, erect or spreading, about 1 mm. long, the divisions terete; capsule 3-lobed, 1.5-3 mm. long, smooth except for many warts near apex and along lobes (or these rarely absent!); columella well-developed, 1.2 mm. long; seed roundish-ovoid, slightly dorsiventrally flattened, brown, 1.3-1.9 mm. long including caruncle, with low sharp irregularly reticulate ridges throughout; caruncle

white, minute, obscurely cordate, vesicular. *E. obtusata* Pursh, *E. dictyosperma* Fisch. & Mey. and vars. *mexicana* Engelm. and *leiococca* Engelm., *E. arkansana* Engelm. & Gray. Abundant nearly throughout Tex., spring; widespread in temp. N.A.

8. *Euphorbia Helioscopia* L. Taprooted annual 1-3 dm. tall, the single main stem (1-) 3-6 mm. thick, slightly swollen just below the pleiochasium, sometimes sparingly branched at the base or just below the pleiochasium; main branches of the main pleiochasium 5, 3-15 cm. long, pseudotrivotomous then several times pseudodichotomous; leaves of main stem and branches alternate, spatulate-obovate, serrate, obtuse or retuse at apex, the lower ones attenuate into a subpetiolar base, 5-40 mm. long, 3-15 mm. broad; leaves of pleiochasium elliptic or obovate, somewhat oblique, smaller and wider in proportion than the stem leaves; cyathia solitary in the forks of the pleiochasium; involucre about 2 mm. long, the small lobes oblong and fimbriate, ciliate; glands 4, transversely elliptical, yellowish, 1 mm. long, 0.5 mm. broad; *staminate flowers* about 15 per cyathium; *pistillate flower*: ovary well-exserted; styles about 1 mm. long, bifid about a third to half their length, the divisions clavellate; capsules subglobose, depressed basally, 2.5-3 mm. long, 3.5-4 mm. thick, roundly tricoccous; seeds ovoid to subglobose, apically somewhat acute, yellowish-brown, about 2 mm. long, 1.5 mm. thick; carunculate, surficially areolate, the depressions 0.2-0.3 mm. broad. *Tithymalus Helioscopius* (L.) Hill. Rare near towns, Rio Grande Plains and probably elsewhere, escaped, spring; introd. widely from Eur.

9. *Euphorbia antisiphilitica* Zucc. CANDELILLA. Cespitose perennial; rhizomes fleshy, 3-10 mm. thick, dark-barked, intricately branched and ultimately leading into numerous erect stems; aerial stems mostly simple, rarely branched, 2-5 (-10) dm. tall or even more, 3-4 mm. thick, terete or when dry longitudinally wrinkled, grayish-green, glaucous with a waxy bloom; nodes with enlarged buttresses, purplish-brown, minutely strigose; leaves alternate, sessile, linear-subulate, 2-3 mm. long, terete, grooved on upper surfaces, brown, minutely pubescent with curved white more or less appressed hairs, early-deciduous, present only on new growth; stipules none or minute and glandular; cyathia solitary or in twos or threes in the upper axils; peduncles about 1 mm. long, purplish-brown, densely strigose; bracts one per peduncle, about 1 mm. long, lanceolate, purplish-brown, densely strigose; involucre campanulate, with 5 round-keeled ridges, 1-1.3 mm. long, purplish-brown, densely white-puberulent; glands 5, alternate with the ridges, purplish-brown, glabrous with shallow central depression, 4 of them oblong and about 0.5 mm. long and 1 mm. wide, the 5th gland round and half as large, each gland with a spreading white to lavender triangular-lanceolate appendage 1.5-2.5 mm. long that is truncate or erose apically; *staminate flowers* 50 to 70 per cyathium; *pistillate flower*: gynophore long-exserted, 3-4 mm. long, recurved, glabrous, purplish, slender but thickened just beneath the ovary; ovary oblong, shallowly 3-lobed, glabrous or minutely scurfy; styles 3, 0.5 mm. long, bifid nearly to the middle, the slender divisions spreading; capsule oblong, shallowly 3-lobed, truncate at apex, 3.5-4 mm. long, widest at the middle, glabrous, greenish or purplish; columella about 3 mm. long, slender, clavellate; seed roundish-ovoid, 2.5 mm. long, whitish, dull, microvesicular, irregularly rugose; caruncle yellowish-vesicular, obscurely cordate, about 0.5 mm. long, sessile. Locally abundant in limestone deserts, lower parts of Hudspeth, Presidio, Brewster and Terrell cos. in the Trans-Pecos, after rains; Tex. s. to Qro. and Hgo.

When boiled in water the branches yield a good grade of wax.

10. *Euphorbia Wrightii* T.&G. Perennial herb 2-5 dm. tall, rushlike or scoparioid; caudexes fleshy or softly white-fibrous woody, 8-14 mm. thick, dark-barked, wrinkled after drying; stems several to numerous at each shoot, 3-5 mm. thick basally, narrowing to 1-2 mm. thick above, much-branched; stems and branches rather strictly ascending, striate; branching usually alternate in lower half, often becoming pseudodichotomous in the upper third; leaves alternate below, becoming opposite above at the floriferous nodes; blades linear to linear-filiform, 2-6 cm. long, 1.5-3.5 mm. wide, margins entire, subcartilaginous; petiole absent or indistinguishable from blade; stipules about 0.1 mm. long, glandlike; cyathia solitary at the upper nodes; peduncles 5-6 (-8) mm. long, slender, glabrous or sparingly strigillose, striate; involucre broadly campanulate, broader than long, 1.3-1.5 mm. long to base of glands or about 3 mm. long including glands and appendages, densely strigose; glands 5, subequal, erect, short-stalked or nearly sessile, rotundly elliptic-oblong, 0.9-1.1 mm. long, flat, cupped or with a shallow longitudinal

depression; appendages white to sordid-pink, semilunate, broader than the gland is long and about as long as the gland is wide, the margin nearly entire or minutely erose-crenate; *staminate flowers* 10 to 15 (to 20) per cyathium; *pistillate flower*: gynophore long-exserted, erect; ovary ovoid, densely white-strigose; styles 3, 0.6-1.2 mm. high or to 1.5-1.8 mm. if unrolled, bifid a fifth to half their length; capsule depressed-globose, 3-lobed (or often 1 of the lobes abortive), 3.7-4.2 mm. long and 4-4.5 mm. broad when fully mature, sparsely strigose to subglabrate; columella 3.5-3.9 mm. long, white, often with three fragile wings; seed plumply round-ovoid, 2.8-3 mm. long, with a few regular prominent pits, a shallow raphe and slight nipple at apex; caruncle minute, not visible without a good lens, set on a slight beveled ventral facet at the micropylar end. Infrequent on dry limestone outcrops, caprock of the Plains Country and w. Edwards Plateau (Garza and Taylor cos. s. to Upton, Pecos and Crockett cos.), summer-fall; also Coah.

11. *Euphorbia strictior* Holz. Perennial herb; stems diffusely branched near the base, 25-80 cm. tall, glabrous except in the upper cyathophorous portion; branches simple below, straight, rigid, striate, alternate below, opposite or pseudodichotomous or trichotomous above; lower leaves alternate, 25-50 mm. long, about 2 mm. broad or less, shorter above, entire, firm, essentially sessile; stipules absent or minute and glandlike; opposite leaves of the upper branches also linear but much shorter; cyathia solitary in the upper forks and axils; peduncles 3-8 mm. long, erect; involucre as broad as high, minutely puberulent; glands 4 or 5, yellowish; appendages merely narrow minutely scalloped margins; *staminate flowers* several per cyathium; *pistillate flower*: ovary well-exserted; styles 3, bifid about a third the length; capsule strongly tricocous; seeds ovoid, about 3 mm. long, gray-green, obscurely pitted, the chalazal end with a large pit. Infrequent in higher parts of the Plains Country (in Panhandle), Aug.-Sept.; apparently endemic.

12. *Euphorbia marginata* Pursh. SNOW-ON-THE-MOUNTAIN. Annual herb; main stem 2-5 mm. thick, erect, 3-10 dm. tall, simple below the pleiochasium, terete, villous on younger portions, glabrate on the older; internodes at midstem 15-40 mm. long; pleiochasial branches 3, terminal, 3 to several cm. long, whorled, divergent, densely villous, several times (repeatedly) dichotomous, the nodes floriferous; leaves of the stem alternate, sessile, oblong to ovate or elliptical, 3-8 cm. long, 2 to 4 times longer than broad, at apex acute or obtuse, at base rounded or subamplexicaul, marginally entire and the uppermost in some specimens with thin white margins, mostly green, thin and glabrous or sparingly ciliate along the margins, with stipules none or minute, glandlike and fugacious; leaves whorled at the base of the pleiochasial branches and opposite at the several forks, those at the forks narrowly lanceolate with white entire margins and apically acuminate; cyathia solitary in the forks of the pleiochasium; peduncles slender, erect, 7-15 mm. long, densely villous; involucre campanulate to turbinate, about 4 mm. long, green, villous; glands 5, oblong, about 1 mm. long, very narrow, cupped, ochroleucous; appendages white, 2-3 mm. long and almost as broad, obtuse, marginally erose; *staminate flowers* about 35 per cyathium; *pistillate flower*: gynophore exserted, reflexed; ovary shallowly 3-lobed; styles 3; capsule depressed-globose, with 3 rounded lobes, 5 mm. broad, usually pubescent; columella well-developed; seed ovoid to globose, about 4 mm. long, dark-gray but beset with light-gray tubercles in a reticulate pattern; caruncle small or absent(?). *Agaloma marginata* (Pursh) Löve & Löve. Locally abundant, usually in calcareous uplands, w. half of Tex. (rare in Rio Grande Plains and Trans-Pecos), late spring-fall; Mont. and Minn. s. to Tex. and N.M.

Cultivated extensively for the showy bracts. Contact with the plant causes dermatitis in many persons.

13. *Euphorbia bicolor* Engelm. & Gray. SNOW-ON-THE-PRAIRIE. Annual herb, very much like *E. marginata* but the leaves and especially the bicolored bracts much narrower, the leaves themselves rarely with white margins; the variegated bracts at the top of the plant linear or oblanceolate-linear, (2-) 3-6 cm. long, (2-) 3-4 (-5) mm. broad, the apexes merely acute. Locally abundant, usually in tight clay soil. Coastal Plain, s.e. Tex., rare inland in e. and n.-cen. Tex., w. to Bell and Travis cos., summer-fall; also Okla.

14. *Euphorbia bifurcata* Engelm. Slender mostly glabrous annual herb, 13-35 cm. tall; main stem erect, 1-2 (-4) mm. thick, rising simply 10-18 cm. and giving way higher to pseudodichotomous floriferous branching; lower branches opposite or alternate, more

slender than main stem, also rising to pseudodichotomies toward the summit, strictly ascending or absent; leaves opposite, occasionally imperfectly so and appearing alternate or occasionally at the base of the first dichotomy in a whorl of 3; blades thin, ovate when mature (upper leaves of the floriferous dichotomies often appearing obovate or oblong when young), truncate or narrowed at base, obtuse or rounded at apex, 17-40 mm. long, 10-27 mm. wide, less than twice as long as broad, sharply serrate marginally, the teeth larger and conspicuous near the base; petioles slender, about as long as the blades of the longer leaves but only about half as long in the smaller less mature blades; stipules minute, glandular; cyathia solitary or in twos or threes in the upper forks, the erect peduncles 0.5-2 (-3) mm. long; involucre obconic, 1.3-2 mm. long; glands 1 or 2 (rarely 3) per cyathium, cupped, short-stalked, oblong; appendage whitish, oblong, 1 to 4 times as long as the gland is wide and a little wider than the gland is long, entire or very slightly emarginate; *staminate flowers* few, only 3 to 5 per cyathium; *pistillate flower*: gynophore rather stout, long-exserted, ordinarily recurved at maturity; styles 3, bifid a little more than half their lengths, 0.8-1 mm. long, the divisions rather stout and flattened; capsule deeply and roundly 3-lobed, flattened basally and apically, 2.6-2.9 mm. long, about 3.5 mm. broad, smooth; columella 2.5-2.6 mm. long, often with 3 lacerate thin wings and apically irregularly clavate; seed ovoid, acute at apex, truncate at base, 2-2.1 mm. long, dark-gray with numerous pale-gray prominent tubercles except the caruncular facet which is smooth; caruncle vestigial, perhaps deciduous and contributing to the clavateness of the columella. *Zygophyllidium delicatulum* Woot. & Standl. Infrequent in creek bottoms, Davis (and perhaps Chisos) Mts. in the Trans-Pecos at elev. above 5,000 ft., July-Sept.; also N.M.

15. *Euphorbia exstipulata* Engelm. Annual herb 5-20 (-30) cm. tall; stems erect, 0.3-2 mm. thick, subglabrous to usually strigose or even densely scurfy-granular especially at the nodes and on the striae; lower branching normal, often decussate; main stem rising 4-15 cm., giving way above to pseudodichotomous floriferous branching; glandlike excrescences present at many of the nodes representing accrescent leaf bases after leaf-fall; leaves opposite; blade symmetrical, linear to ovate (see varieties), marginally subcartilaginous; petioles short and indistinct (blades long-acuminate to base); stipules minute, glandlike; cyathia solitary in the forks; peduncles stout, 0.5-1.5 mm. long; involucre 1-2 mm. long including the glands; glands 4, narrowly oblong to roundish, 0.5 mm. long, with a central depression or cup; appendages white, half to three times as long as wide, truncate to erose or lacerate or lacinate, occasionally regularly 2- to 4-fid to the base, the divisions triangular; appendages rarely obsolete or reduced to a narrow border; *staminate flowers* 8 to 14 per cyathium, often crowded to one side in the involucre by the developing gynophore after pistillate anthesis; *pistillate flower*: gynophore exerted, eventually recurved; styles 3, 0.8-1 mm. long, erect, bifid more than half their length; capsule ovoid-triangular, as broad as long, 2.5-3.4 mm. long; columella 2-2.4 mm. long; seed 2.2-2.9 mm. long, ovoid-quadrangular, broad and truncate at base, narrowed to micropylar end, with 2 broad tuberculate transverse ridges and a slight widening at the narrow apical end, with rounded protuberances at intersections of the ridges and longitudinal angles, beveled on the ventral apex, the surface buffy-fuscous, mottled gray or brown to grayish-white or almost chalky-white at times, microvesicular; caruncle minute, whitish, obscurely reniform, 0.1 mm. long or shorter.

Represented with us by 2 varieties as follows:

Var. *exstipulata*. Leaves including petioles 15-60 mm. long, 2-8 cm. broad; blades thin, linear to lanceolate, gradually acuminate to base, with teeth parallel to the margin; ratio of length including petioles to maximum width of the leaves at midstem greater than 5, often 8 to 12 or more; dimensions of the other parts of the plants usually approaching the lower limits given in the general description. Usually in shallow calcareous soil over limestone at moderate elev., less common in sandy soil over basic igneous rock, rarely in gypsiferous soil, in the Trans-Pecos, summer-fall; Tex., N.M., Ariz., Coah., Chih. and Son.

Var. *lata* Warnock & M. C. Johnst. Leaves including petioles 1-3 (-5) cm. long, 6-28 mm. broad; blades firm or at times subchartaceous, rather abruptly narrowed toward the bases, ovate to ovate-lanceolate, with salient teeth and slight tendency to roll; ratio of length including petioles to maximum width of leaves at midstem less than 5, often only

2 or 3; dimensions of other parts of plants usually approaching the upper limits given in the general description above. Infrequent in a variety of soils, Brewster and Presidio cos. in the Trans-Pecos, summer-fall; also Chih.

Some plants in Texas and Arizona are intermediate between these two varieties.

16. *Euphorbia hexagona* Nutt. Taprooted annual, usually with one stem from the base, (2-) 4-10 dm. tall, decussately and pseudodichotomously branched, the branches ascending, minutely strigillose; leaves opposite; blades linear, (15-) 20-50 mm. long, 1-3 mm. broad, acute at both ends, entire; petioles 1-3 mm. long; stipules absent or minute and glandlike; cyathia solitary in the upper forks and axils, on peduncles about 1 mm. long; involucre campanulate, about 1.5 mm. long, strigillose; glands 5, transversely elliptical, about 0.6 mm. long and 0.2 mm. broad, deeply cupped, olivaceous; appendages whitish or greenish-white, deltoid, about twice as long as the gland is broad; *staminate flowers* 20 to 40 per cyathium; *pistillate flower*: ovary long-exserted, subglobose; styles 0.5-0.8 mm. long, bifid about half their length, the branches subclavate; capsule about 4 mm. long, shallowly tricoccus; seeds 2.8-3 mm. long, ovoid, with low bumps scattered all over the surface, not angular nor deeply pitted. In loose sandy soil, local, Plains Country and n.-cen. Tex., late summer; Neb. and Colo., s. to Tex.

17. *Euphorbia bilobata* Engelm. Slender annual herb 15-40 cm. tall; main stem erect, 0.5-2.5 mm. thick, rising 5-20 cm. before giving way to pseudodichotomous floriferous branching above; lower branches normal, often decussate, more slender than main stem, ascending; leaves opposite; blades linear to linear-oblong, acute apically, long-tapering basally, 15-40 mm. long, 1.5-4 mm. wide (but folded along midvein in drying, appearing narrower), about 10 to 20 times longer than wide, entire marginally; petioles 2-3.5 mm. long; stipules oblong, about 0.05 mm. long, glandlike; cyathia solitary in the upper forks; peduncles 1-2.2 mm. long, slender; involucre narrowly campanulate, 1.1-1.6 mm. long including the glands and erect appendages; glands 5, subequal, flat or shallowly cupped, each deeply 2-lobed distally, with lobes pointing up, the whole thus broadly reniform or obcordate, 0.5 mm. long measured parallel with the lobes and 0.7 mm. long measured across the lobes; appendages white, 2 per gland (one on each lobe or one per gland bilobed to the base), erect, a little longer than the lobes of the gland, narrowly triangular or lanceolate, usually acute; *staminate flowers* 9 to 16 per cyathium; *pistillate flower*: gynophore long-exserted and reflexed at maturity; styles 3, bifid a third to half their length, 0.6-0.8 mm. long, erect; capsule deeply 3-lobed, 1.9-2.1 mm. long, about 2.5 mm. broad; columella about 1.3 mm. long; seed oblong-ovoid, weakly quadrangular in transverse section, with 4 or 5 strong transverse sulci on each facet, strongly angulate-tuberculate especially at the intersections of the transverse costae and longitudinal angles, dark reddish-brown to black, microvesicular, 1.8-1.9 mm. long, truncate basally; caruncle irregular and indistinct or appearing absent, sessile, vesicular, whitish. Rare along creeks, Davis Mts. and Eagle Mts. in the Trans-Pecos at elev. above 5,500 ft., Aug.-Sept.; Ariz., N.M. and Tex.

18. *Euphorbia eriantha* Benth. Robust annual herb 2-5 dm. tall; main stem 3-12 mm. thick, erect; branches numerous, usually alternate, occasionally opposite near base of plant, divergent or usually strict, ascending or erect; leaves alternate or occasionally appearing opposite; blades linear to linear-lanceolate, (2-) 4-6 (-7) cm. long, 1-6 mm. wide, at apex attenuate and mucronate, at base attenuate, marginally entire or with a few remote teeth; petioles 3-6 mm. long, strigose; stipules minute, glandlike; cyathia solitary or in irregular dense corymbiform clusters of 5 to 20 at summits of stems, the clusters subtended by whorls of 3 to 8 or many bracteal leaves; peduncles erect, 2-3 mm. long, whitish, densely scurfy-strigose; involucre turbinate, about 2 mm. long and broad, densely white-strigose; glands 3, very rarely 4, sessile, roundish, cupped, grayish; appendages each of 5 to 7 grayish strigose linear lobes attached at the exterior margin and curved upward and inward over the gland to hide it; *staminate flowers* 25 to 35 per cyathium; *pistillate flower*: gynophore exserted and reflexed at maturity; styles 3, entire, tapering to the apex, about 1 mm. long; capsule ovate-oblong to oblong, obscurely 3-lobed, longer than broad, about 5 mm. long, densely strigose; columella 4-4.2 mm. long; seed oblong, weakly quadrangular, 4 mm. long, truncate, dorsiventrally compressed, with 3 to 4 low rounded transverse ridges most noticeable on the ventral facets, mottled gray and white; caruncle reniform, 0.8 mm. long, wider than long, yellowish-vesicular. Desert

or subdesert areas, s. Brewster and Presidio cos. in the Trans-Pecos, Jan.-July; Tex. and Coah. w. to Calif. and Baja Calif.

19. *Euphorbia corollata* L. Perennial glabrous or minutely puberulent herb, (1-) 2-8 dm. tall; roots dark-barked; stems one or few from the crown, erect or ascending, with branches few and alternate for most of the length, opposite and pseudodichotomous or -trichotomous in the uppermost (cyathophorous) portion; leaves alternate (opposite or whorled only in the uppermost cyathophorous portion); leaf blade of the midstem (1-) 2-4 (-6) cm. long, mostly oblong or less commonly linear, rounded at apex, acute at base, entire marginally, the petioles short; opposite leaves much smaller, nearly sessile; stipules minute, glandlike; cyathia solitary in the upper forks; peduncles (1-) 2-30 mm. long; involucre campanuloid, 1.5-3 mm. long and broad; glands 5, cupped, transversely linear, 0.6 mm. long, 0.2 mm. broad; appendages 1.5-4 mm. long, white, conspicuous; *staminate flowers* about 10 to 15 per cyathium; *pistillate flower*: styles 3, about 0.7 mm. long, bifid about half their length, the divisions clavellate; capsule 2.5-4 mm. long, roundly tricoccous; seed 2.3-2.5 mm. long, ovoid, smooth, white. Incl. var. *angustifolia* Ell. and var. *mollis* Millsp., *E. paniculata* L., *E. ziniiflora* Small, *Agaloma corollata* (L.) Raf., *A. angustifolia* (Ell.) Raf. Frequent in sandy soils, e., s.e. and n.-cen. Tex., rare w. to e. edge of Edwards Plateau, June-Nov.; s.e. U.S.

20. *Euphorbia innocua* Wheeler. Perennial herb; roots 2-10 mm. thick, to 3 dm. long, deeply buried and tenacious; stems several from the crown, prostrate to decumbent or (in thick herbaceous vegetation) ascending, (5-) 10-45 cm. long, weak, often flattened, densely pilose with hairs to 1 mm. long; branches alternate below, pseudodichotomous at the cyathiferous nodes; leaves alternate below, opposite above, all rather densely pilose, alternate ones short-petiolate, the opposite ones subsessile; blades ovate to broadly oblong to even bluntly deltoid, 1 to 2 times as long as broad, 8-30 mm. long, entire, basally often shallowly cordate, apically blunt or rounded; stipules glandlike, minute; cyathia solitary in the distal forks on peduncles about 1 mm. long; involucre 1.5-2.5 mm. long and broad, campanuloid, densely pilose; glands 4, transversely elliptic, about 0.6 mm. long, 0.2 mm. broad, glabrous, cupped; appendages greenish white, a little longer than the gland is wide and wider than it is long, pilose beneath; *staminate flowers* 6 to 9 per cyathium; *pistillate flower*: ovary shortly exserted, pilose; styles 0.6-0.7 mm. long, bifid about half their length, the divisions subclavate; capsule depressed-globose, roundly tricoccous, 2.4-2.8 mm. long; seeds 1.6-1.8 mm. long, ovoid, white-ridged and shallowly brown-pitted all over, ecarunculate. *E. refugii* Croizat. Infrequent in sands near the coast, Refugio Co. to Willacy Co., late summer-Dec. (also spring); endemic.

21. *Euphorbia radians* Benth. Mostly glabrous perennial herb; fleshy tuberous root vertical, 5-13 mm. thick, branching toward the crown, brownish, deeply fissured in dried specimens; stems 5 to 20, 1-2 mm. thick, ascending or erect, 12-25 cm. long, essentially simple, glabrous; internodes 3-10 cm. long; floriferous branches very sparsely leafy and vernal; sterile branches leafy and appearing after anthesis; leaves alternate and sessile; blades on the floriferous stems few, 5-7 mm. long, oblong or oblanceolate, green, strigose along the entire margin; blades on sterile branches linear, 2-4 cm. long, densely long-strigose, attenuate at both ends, marginally entire; stipules for both kinds of leaves brownish, glabrous, glandular and minute; cyathia 4 to 8 in irregular corymbiform terminal clusters, subtended by a whorl of 5 to 9 or more bracteal leaves which are whitish to pinkish, somewhat green toward the apex, lanceolate to oblanceolate, 15-30 mm. long, sessile and glabrous; peduncles 1-3 mm. long, stout, purplish, erect; involucre campanulate, 3 mm. long, broader than long, glabrous, greenish to brownish, with 5 white long fimbriate lobes at the summit; glands 1 to 3, deeply cupped, pinkish or purplish, oblong, fleshy, exappendiculate; *staminate flowers* 40 to 50 per cyathium; *pistillate flower*: gynophore very long-exserted and reflexed at maturity; styles 3, stout, recurved, glabrous, bifid two thirds their length, the divisions tapered to the apex; capsule obovate to ovate, 4-5 mm. long, obscurely 3-lobed, brownish, glabrous; columella unknown; seed 4-5 mm. long, narrowly ovoid, with a smoothish white coat and shallow irregular brownish depressions all over; caruncle a minute glandlike structure about 0.2 mm. in diameter. *Poinsettia radians* (Benth.) Kl. & Gke. Grama grasslands, above 4,500 ft. elev. in the Trans-Pecos, Mar.-May; Oax. n.w. to Ariz. and Tex.

22. *Euphorbia dentata* Michx. Annual herb 1-4 (-6) dm. tall; main stem erect, 1-4 mm. thick, with dense short sordid retrorse pubescence and also some relatively long white trichomes; branches decussate, generally many, more slender than main stem, ascending, often as tall as main stem; leaves opposite, rarely alternate; blades narrowly lanceolate to narrowly ovate, 15-60 mm. long, acute at apex, acuminate and shortly attenuate at base, marginally dentate, sparsely scurfy-pubescent beneath; petioles 5-25 mm. long, pubescent like the stems; stipules absent or minute and glandlike; cyathia irregularly clustered at summits of stems, the clusters subtended by opposite leaves that are somewhat pale but never discolored basally; peduncles 1-2 mm. long, glabrous, erect; involucre campanulate, 1.5-2.2 mm. long, glabrous, laciniately toothed, greenish; glands 1 to 3, short-stalked, cupped, exappendiculate; *staminate flowers* many per cyathium; *pistillate flower*: gynophore stout, exserted, reflexed at maturity; ovary broader than long, roundly 3-lobed, glabrous; styles 3, 1-2 mm. long, bifid nearly to the base, the divisions slender; capsule shallowly 3-lobed, 2-3 mm. long, 4-5 mm. broad, green, glabrous; columella narrowly 3-winged, 2.5 mm. long; seed plump, ovoid to subspherical, 2.2-2.5 mm. long, dark-brown, densely microtuberculate, pointed apically; caruncle situated on beveled ventral surface at micropylar end, short-stalked, yellowish-vesicular, heart-shaped, about 0.6 mm. long. *Poinsettia dentata* (Michx.) Kl. & Gke. Abundant in a variety of soils throughout, spring-fall; s. Mex. to Ariz., Wyo., S.D., Minn. and N.Y.

23. *Euphorbia cyathophora* Murr. Mostly glabrous herbs 2-5 (-7) dm. tall, annual in our area; taproot yellowish, 2-7 mm. thick, vertical; main stem 1-5 mm. thick, erect, greenish, 2-7 dm. tall; branches few to many, often decussate at the lowermost nodes, alternate at midstem, pseudodichotomous in the uppermost (inflorescence) regions, more slender than main stem, ascending to erect, equal to main stem in height, green; internodes at midstem 5-10 cm. long; leaves opposite or occasionally alternate; blades linear-lanceolate to linear or narrowly obovate, the wider ones panduriform, acuminate at both ends, 6-15 cm. long, marginally serrate or entire, bright, rather glossy-green, rather thin, usually with scattered minute appressed hairs on lower surfaces, the uppermost leaves often with small reddish splotches near the base; petioles very slender, 4-12 mm. long; stipules absent or minute and glandlike; cyathia irregularly clustered at summit of stem and branches (actually terminal in the extreme distal pseudodichotomies with greatly shortened internodes), the clusters subtended by decussate leaves that are pale-reddish basally; peduncles stout, costate, 1.5-3 mm. long, glabrous, broadened just beneath the involucre; involucre narrowly urceolate-campanulate, 2-2.5 mm. long, toothed; gland usually solitary, deeply cupped, shallowly bilabiate, with a narrowly oblong opening 1 mm. long, green, sessile, exappendiculate; *staminate flowers* many per cyathium; *pistillate flower*: gynophore long-exserted and reflexed at maturity; ovary roundly 3-lobed, essentially smooth, green; styles 3, about 2 mm. long, bifid about a third their length; capsule roundly 3-lobed, 3-4 mm. long, 5-6 mm. broad; columella about 2 mm. long, narrowly 3-winged; seed ovoid or subglobose, not angular, 2.9-3.1 mm. long including caruncle, truncate at the base, pointed at the apex, dark-brown but covered with low pale-brown tubercles; caruncle very small. *Poinsettia cyathophora* (Murr.) Kl. & Gke. Scattered throughout the state, though rare in the deeper soils of the Coastal Plain, May-Sept.; rather widely distributed in temp. N.A., s. to Oax.

The name *E. heterophylla* has for a long time been used for both this species and the next, through failure to observe their distinctness. Plants of this species are often cultivated for the attractive bracts.

24. *Euphorbia heterophylla* L. CATALINA. Annual herbs (1-) 2-8 dm. tall; main stem 1-5 mm. thick, erect, (1-) 2-8 dm. tall; branches several and the lowermost 1 or 2 nodes opposite but always alternate over most of the height, then pseudodichotomous at the extreme top of the plant (inflorescence-region) and more slender then but almost as high as the main stem; internodes at main stem (3-) 5-11 cm. long; leaves opposite at the lowest 1 or 2 nodes, alternate over most of the height, opposite again in the uppermost (inflorescence) region; blades mostly ovate to ovate-elliptic or rhombic-ovate, rarely notched at the sides (panduriform), rarely broadly lanceolate, (3-) 4-10 cm. long, marginally serrate (rarely subentire), acute at apex, rounded to acuminate at base, thin, the uppermost blades (subtending the clusters of cyathia) never red basally but often slightly discolored whitish or purplish near the base; petioles (5-) 10-40 mm. long, often sparsely hispid; stipules absent or minute and glandlike; cyathia irregularly clustered at

summit of stem and branches; peduncles stout, 1-3 mm. long; involucre narrowly urceolate-campanulate, 2-2.5 mm. long, toothed; gland usually solitary, deeply cupped, with a circular opening much less than 1 mm. broad, green, short-stalked, exappendiculate; *staminate flowers* numerous; *pistillate flower*: gynophore long-exserted and reflexed at maturity; ovary roundly 3-lobed, essentially smooth, green; styles 3, 1-2 mm. long, bifid about half their length; capsule roundly 3-lobed, 4 mm. long, 6 mm. broad; columella about 3 mm. long, narrowly 3-winged; seed ovoid, 3-3.5 mm. long including caruncle, truncate basally, in transection angular (with a dorsal keel and 2 lateral angles), dark brownish-gray mottled, with coarse blunt tubercles; caruncle very small. *Poinsettia heterophylla* (L.) Kl. & Gke. Infrequent in loamy soil, Rio Grande delta in extreme s. Tex., waifed elsewhere near the coast, spring-fall; widespread in trop. Am.

25. *Euphorbia acuta* Engelm. Strongly perennial herb; rhizomes stout, woody, 3-15 mm. thick, at least 1 dm. long and occasionally longer than 9 dm., dark-barked, gemmiferous, often vertical near the crown but horizontal and spreading deep underground; stems several to many from the woody crown, erect or ascending, (5-) 10-20 (-30) cm. long, 0.5-1.5 mm. thick, often densely white-woolly when young, often pseudodichotomously branched distally; leaves opposite; blades ovate-acuminate to ovate-lanceolate, 8-15 (-20) cm. long, 3-8 mm. wide, rather rigid, olive-green, sparingly long-villous to densely canescent-appressed-tomentose beneath, less pubescent or glabrate above, marginally entire and subcartilaginous, often revolute, produced at acute apical angle into a sharp spinulose point, at base subequilateral and rounded or truncate; petioles shorter than 1 mm., white-woolly to glabrate; stipules minute to absent; cyathia solitary at the nodes, often in the upper forks; involucre narrowly campanulate to usually urceolate, 1.8-2.2 mm. long, whitish-villous or strigose; glands 4, oblong-elliptic; appendages 0.5-1 mm. long, uniformly crenate, white, ascending to erect; *staminate flowers* 20 to 25 per cyathium; *pistillate flower*: gynophore exserted, villous; styles 3, bifid about half their length, about 1 mm. long; capsule oblong-triangular, 2.8-3.1 mm. long, white-villous, more densely so on the angles; columella 2.7-2.8 mm. long; seed oblong, distinctly quadrangular, 2.2-2.5 mm. long, facets slightly concave, superficially microreticulate, white, ecarunculate. *Chamaesyce acuta* (Engelm.) Millsp. Common in dry limestone uplands, Edwards Plateau, e. to Uvalde Co., w. to Crane, Pecos and Brewster cos., Apr.-Nov.; N.M., Tex. and Coah.

26. *Euphorbia angusta* Engelm. Perennial herb 10-45 cm. tall; taproot woody, 3-10 mm. thick, slenderly napiform or branched at one or both ends; stems 6 to 50 from the woody crown, erect, 10-45 cm. long, sparingly branched (branching occasionally pseudodichotomous distally), strigose; leaves opposite; lowest (spring) blades elliptic to linear-oblong, 7-25 mm. long, acute at both ends, marginally entire, glabrous above, strigose beneath; higher (summer) blades narrower, linear, more than 12 times as long as broad, acute at both ends or basally rounded, marginally entire, strigose below, less densely so above; petioles 0.5-1.5 mm. long; stipules minute, distinct, subulate, about 0.3 (-0.9) mm. long, deciduous, apparently often absent except for glandlike bases; cyathia solitary at the distal nodes or in the forks; involucre narrowly campanulate, about 1 mm. long, strigose; glands 4, narrowly oblong, depressed centrally; appendages white, 2 or 3 times as long as gland is wide, erect or ascending, marginally erose or irregularly toothed; *staminate flowers* 16 to 26 per cyathium; *pistillate flower*: styles 3, shortly bifid, about 0.5 mm. long, the divisions spreading and clavellate; capsule ovoid, roundly triangular, 2-2.6 mm. long, broader than long, strigose; columella 1.9-2.2 mm. long; seed broadly oblong, 1.5-2 mm. long, 1.3-1.4 mm. thick, bluntly quadrangular, grayish-white to chalky, with a few low irregularly anastomosing transverse ridges, ecarunculate. *E. Nealleyi* Coult. & Fish., *Chamaesyce angusta* (Engelm.) Small. Frequent, Edwards Plateau, from Travis and Bexar cos. w. to Tom Green, Pecos and Brewster cos., spring-fall; endemic.

27. *Euphorbia lata* Engelm. Perennial herb 5-15 cm. tall; rhizomes slender, 2-5 mm. thick, shallowly buried, gemmiferous with shoots at intervals, branched, at least 3 dm. long in some specimens; stems solitary or several at each shoot, erect or ascending, 1-3 cm. long, reddish-brown, crisply white-pubescent to glabrate, giving way above to pseudodichotomous branching with internodes 5-20 mm. long and greenish-gray, densely crisply white-hairy; leaves opposite; blades narrowly to broadly deltoid, occasionally acuminate, usually falcate and appearing narrower by revolution of the entire margin,

4-12 mm. long, 2-9 mm. wide, truncate at base, above grayish-brown to olive-drab or sordid, minutely crisply white-hairy, beneath white-strigose; petioles 0.5-1 mm. long, densely white-strigose; stipules united, subulate, about 1 mm. long, densely white-strigose; cyathia solitary in the distal forks; involucre campanulate, 1-1.3 mm. long to base of glands, crisply white-hairy; glands 4, short-stalked, oblong, folded or shallowly cupped, 0.5-0.8 mm. long; appendages occasionally obsolete, usually well-developed, ochroleucous, about as long as gland is wide or shorter, semilunate, marginally erose to crenate; *staminate flowers* 12 to 35 per cyathium; *pistillate flower*: styles 3, 0.3-0.8 mm. long, bifid almost to the base, the spreading divisions blood-red and clavate; capsule ovoid-triangular, 1.9-2.3 mm. long, about as broad as long, acutely angled, white-strigose especially on the angles; columella 1.5-1.8 mm. long; seed oblong, obscurely quadrangular, 1.5-1.8 (-2) mm. long, apically acute, ventral facets often concave, superficially smooth, brownish to white, ecarunculate. *Chamaesyce lata* (Engelm.) Small. Dry calcareous sandy plains, Plains Country, Trans-Pecos and w. part of Edwards Plateau (rarely e. as far as Coryell Co.), Apr.-Sept.; Colo. to Kan. s.w. to Coah. and Tex.

28. *Euphorbia carunculata* Waterfall. Prostrate glabrous annual herb; stems several to many, 2-4 mm. thick, prostrate, 1-10 (-15) dm. long, somewhat succulent, buttressed at the nodes, branching pseudodichotomous distally; internodes 2-12 cm. long, usually much longer than the subtending leaves; leaves opposite; blades ovate to elliptic-oblong, 10-26 mm. long at midstem and usually about half as broad, at apex acute (85-95°) and mucronate, at base slightly asymmetrical and truncate or even occasionally shallowly cordate, marginally entire, rather firm and with no tendency to roll on drying; petioles 3-7 mm. long; stipules lanceolate, 0.9-1.8 mm. long, bifid, rarely trifid, the divisions subulate, thin to subscarios; cyathia solitary in the forks and at the distal nodes; peduncles elongating after anthesis to 3-6 (-7) mm.; involucre broadly campanulate, 2-2.2 mm. long to base of glands; glands 4, short-stalked, erect, rotund, 0.3-0.8 mm. long, 0.2-0.7 mm. wide, flat or usually cupped; appendages sometimes absent, sometimes forming a mere narrow margin or in some specimens prominent, erect, yellowish, 0.8-1.1 mm. long, 0.8-1.5 mm. wide, with entire or erose margin; *staminate flowers* (15 to) 18 to 26 per cyathium; *pistillate flower*: styles 3, 0.7-0.8 mm. long, bifid about a third their length, the divisions tapering to a mucro; capsule ovoid, narrowed apically, narrowly truncate basally, (4.5-) 5-6 mm. long, 4-5 mm. broad, deeply 3-lobed, the lobes sharply angled; columella 4-5 mm. long, slender, whitish, clavellate; seed very distinctive, laterally compressed, not at all angulate except perhaps medially near the micropyle, acuminately narrowed from base to micropylar end, (3.7-) 4.3-5 mm. long, 1.6-2 mm. thick radially near the base and 0.7-0.9 mm. tangentially, grayish-white or mottled reddish-brown or fuscous, much paler to even whitish at the apex which is enlarged or apiculate dorsally and reflexed very slightly away from the raphe; "caruncle" (if it is properly to be called that) actually rather small, linear, white, 0.5 mm. long, protruding slightly in the median ventral angle at the micropylar end. *Chamaesyce carunculata* (Waterfall) Shinners. Locally plentiful in loose quartz dune sand, Plains Country (Crane, Hardeman, Ward, Wheeler, and Wilbarger cos.), summer-fall; Okla., Tex. and Chih.

29. *Euphorbia ammannioides* H.B.K. Glabrous annual herb, often glaucous; stems 6 to 25, prostrate, 5-100 cm. long, 0.4-2 mm. thick; leaves opposite; blades usually narrowly oblong, about 3 times as long as broad, 4-15 mm. long, at apex obtuse or sometimes mucronate, oblique and obtuse or rounded at base, marginally entire; petioles 1-2 mm. long; stipules distinct, 1-1.3 mm. long, parted into usually 3 linear segments; cyathia solitary in the upper forks; involucre campanulate, 1-1.6 mm. long to the base of the gland; glands 4, usually elliptical, 0.4-0.6 mm. long; appendages usually about twice as long as the gland is wide; *staminate flowers* 4 to 13 (rarely to 16) per cyathium; *pistillate flower*: styles 3, 0.2-0.5 mm. long, bifid about half their length, the branches often slightly thicker than the united basal portion; capsule ovoid, triangular, about 2 mm. long, broader than long, the 3 lobes usually narrowly rounded; columella 1.7-1.8 mm. long; seed ovoid, plump, very shortly if at all acute at apex, 1.2-1.6 mm. long, about 1 mm. thick, pale reddish-brown to nearly white, ecarunculate, essentially smooth. *Chamaesyce ammannioides* (H.B.K.) Small. Abundant on loose fine sands along the coast and in extreme s. Tex. inland as far as Brooks Co., spring-fall; Coastal States, Va. to Ver., and nearly all Gulf and Carib. beaches.

Exceedingly closely related to and probably conspecific with *E. Geyeri*. According to recent work by A. Dugand, the correct name for this species may be *E. bombensis* Jacq.

30. *Euphorbia Geyeri* Engelm. Glabrous annual herb; stems 6 to 25, prostrate, 5-45 cm. long, 0.4-1.4 mm. thick; leaves opposite; blades oblong to ovate-oblong or elliptic-oblong, 4-11 mm. long, about twice as long as broad, obtuse or emarginate at apex, often mucronate, oblique and obtuse or rounded at base, marginally entire; petioles 1-2 mm. long; stipules distinct or the ventral united occasionally, 1.1-1.5 mm. long, usually trifid, the divisions filiform; cyathia solitary in the upper forks; involucre turbinate to narrowly campanulate, 0.9-1.5 mm. long to the base of the glands; glands 4, broadly oval to round, 0.2-0.4 (-1.6) mm. long; appendages white, half to twice as long as the gland is wide, entire to slightly erose or absent (see varieties below); *staminate flowers* 5 to 15 (to 25) per cyathium, pale, even the anthers often whitish or ochroleucous, not yellow as in most species; *pistillate flower*: styles 3, usually erect and fairly rigid, 0.2-0.3 (-0.6) mm. long, bifid a third to a half their length, the divisions terete to subclavate; capsule ovoid, triangular, about 2 mm. long and 2.5 mm. broad, the 3 lobes angular to narrowly rounded; columella 1.7-1.8 mm. long; seed ovoid, plump, acute at apex, 1.3-1.4 (-1.6) mm. long, 1 mm. thick, pale reddish-brown to nearly white, ecarunculate, superficially smooth. *Chamaesyce Geyeri* (Engelm.) Small. Plants of sandy soils, widely distributed and actually making up the inland race of the coastal *E. ammannioides*.

We have two races as follows:

Var. *Geyeri*. Glands with appendages. Sandy soils of the Plains Country, s. and w. to Ward, Winkler and Crane cos., rarely e. to n.-cen. Tex.; N.D., Wisc., Minn. and Ia. s. to our area.

Var. *Wheeleriana* Warnock & M. C. Johnst. Glands without appendages. Rare and local in dune areas in the e. part of El Paso Co.; endemic.

31. *Euphorbia Parryi* Engelm. Glabrous annual herb; stems 5 to 25, 0.5-3 mm. thick, prostrate in our area, 10-50 (-85) cm. long; leaves opposite; blades linear, 5-28 mm. long, (5 to) 8 to 12 times as long as broad, rounded and mucronate at apex, slightly inequilateral at base, marginally entire; petioles 1-2 mm. long; stipules distinct, triangular, 0.8-1.2 mm. long, usually deeply bifid, the divisions narrowly lanceolate to subulate, whitish to purplish with a definite narrow yellowish transverse zone of abscission basally; cyathia solitary in the upper forks; involucre campanulate-calyculate, 1-1.2 (-1.5) mm. long to the base of the glands; glands 4, rotundly elliptic, deeply cupped, 0.3-0.5 mm. long; appendages narrow, white, forming a margin on the gland, entire, occasionally as long as the gland is wide, usually erect or sometimes forming a cup; *staminate flowers* 34 to 55 per cyathium, the anthers yellow; *pistillate flower*: styles 3, rather short, rigid, 0.7-0.8 mm. long, white to ochroleucous, bifid a third to two thirds their length, the divisions terete; capsule globose to ovoid, triangular or even more deeply 3-lobed, 2-2.1 mm. long; columella about 1.8 mm. long, clavate; seed ovoid, plump, acute, very obscurely and roundly triangular, 1.3-1.5 (-1.8) mm. long, about 0.9 mm. thick, uniformly pale reddish-brown to tawny-white or occasionally mottled brown and white, ecarunculate. *Chamaesyce Parryi* (Engelm.) Rydb. Local in blowing sand areas of the Trans-Pecos (El Paso and Culberson cos.), July-Nov.; Calif. and Ut., s.e. to Tex.

Closely related to *E. missurica* and doubtless to be considered merely the western race of that species.

32. *Euphorbia missurica* Raf. Glabrous annual herb to 1 m. tall; stems several, ascending to erect or often arcuate-ascending, 7-100 cm. long, 0.5-4 (-6) mm. thick, much-branched; leaves opposite; blades linear to oblong, at midstem 10-28 mm. long, 1.5-5 mm. broad, 4.7 to 14 times as long as broad, rounded to truncate or subemarginate at apex, occasionally subacute and often mucronate, at base narrowed or shortly rounded and slightly asymmetrical, marginally entire, usually folded up along the midvein or revolute; petioles 1-2 (-3.2) mm. long, slender; stipules linear to triangular-subulate, distinct to partly united, entire to parted, 1-1.5 mm. long, the divisions subulate, whitish or purplish with a distinct narrow yellow transverse zone of abscission basally; cyathia solitary in the upper forks or appearing cymose by shortening of the distal internodes and leaves; involucre narrowly to broadly campanulate, 1.2-1.7 mm. long to base of glands; glands 4, round or slightly elliptic, 0.2-0.4 mm. in diameter, cupped or folded; appendages white to pink, ovate, entire, subacute to rounded, occasionally emarginate, 1.5 to 4 times as

long as gland is wide, usually spreading and often reflexed or arched outward; *staminate flowers* 29 to 53 per cyathium; *pistillate flower*: styles 3, white, 0.7-1.2 mm. long, rather stout, bifid half their length, the terete divisions usually arched and widely spreading; capsule globose-ovoid, roundly triangular or more deeply 3-lobed, 2-2.5 mm. long, 2.5-3 mm. broad; columella 1.9-2.1 mm. long; seed plumply ovoid to broadly ovoid-triangular, 1.8-2 mm. long, 1.2-1.4 mm. thick, brownish-white, the angles (if any) broadly rounded, ecarunculate. Incl. var. *intermedia* Wheeler, *Chamaesyce missurica* (Raf.) Shinnors and var. *callicola* Shinnors. Common and widespread e. of Trans-Pecos (rare in extreme e. Tex.), June-Nov.; Minn. to Mont., s. to Tex. and N.M.

There have been attempts to distinguish "varieties" on the proportions of the leaves, the angularity of the achenes and the length of peduncles. There is a slight tendency toward narrower leaves on calcareous soils and broader ones on sandy soils, but it is absolutely impossible to erect meaningful varieties in our area.

33. *Euphorbia revoluta* Engelm. Glabrous annual herb 3-23 cm. tall; main stem erect, 2-6 cm. long, 0.7-1.1 mm. thick, giving way above to widely divergent pseudodichotomous branching, the branches progressively finer and wirelike, the ultimate ones 0.14-0.25 mm. thick, dark-purple or almost black, occasionally yellowish on one side and black on the other; leaves opposite; blades narrowly linear, 2.5-26 mm. long, 1-1.2 mm. broad, usually 9 to 13 times as long as broad, acute at apex, in some specimens mucronate, almost symmetrical and acute at base, marginally entire, revolute, green, firm; petioles 0.5-1.5 mm. long; stipules distinct, entire, linear-subulate, 0.3-0.8 mm. long; cyathia solitary in the forks or appearing cymose-clustered by shortening of distal internodes; involucre shortly campanulate, 0.7-0.9 mm. long to base of glands; glands 4, discoid, 0.15-0.3 mm. across, lightly cupped; appendages white to dark-purple, occasionally obsolete, usually shortly ovate, a little shorter than to occasionally a little longer than the gland is wide, spreading, rather rigid, marginally entire; *staminate flowers* 3 to 8 per cyathium; *pistillate flower*: styles 3, 0.3-0.5 mm. long, white, rather stout, entire or very shortly notched apically; capsule ovoid, acutely triangular, basally truncate, 1.3-1.7 mm. long; columella 1.2-1.5 mm. long; seed ovoid, sharply angled, 1.2-1.3 mm. long (to 1.5 mm. when moistened) and 0.7-0.8 mm. thick (1.1 mm. when moistened), very slightly flattened dorsiventrally, with about 3 prominent transverse ridges, these not or scarcely involving the angles; "testa" brownish, covered with a thick white coat which is hydrophilic and upon moistening becomes a thick white mucilaginous villous fur, ecarunculate. *Chamaesyce revoluta* (Engelm.) Small. Locally abundant on rocky desert slopes in the Trans-Pecos (El Paso, Hudspeth, Jeff Davis, Presidio and Brewster cos.), July-Oct.; Colo., s. to Chih. and w. to Ariz.

34. *Euphorbia hyssopifolia* L. Annual mostly glabrous herb to 6 dm. tall; main stem erect, 0.8-3 mm. thick, a few cm. tall, giving way above to ascending branches, pseudodichotomous distally; stems occasionally with scattered pilose hairs especially on the younger parts; leaves opposite; blades lanceolate to oblong, often falcate, 5-30 mm. long, rounded to very acute at apex, inequilateral and rounded to truncate at base, marginally serrate, occasionally some pilose hairs on blades (especially near the bases); petioles 1-1.5 mm. long; stipules mostly united or at distal nodes partly distinct; cyathia solitary in the distal forks and by shortening of internodes clustered; involucre turbinate, 1.2-1.7 mm. long to base of glands; glands circular to slightly elliptic, 0.15-0.3 mm. long; appendages white to reddish or purplish, semilunate, much shorter than to twice as long as the gland is wide, entire; *staminate flowers* 4 to 15 per cyathium; *pistillate flower*: styles 3, 0.5-0.9 mm. long, bifid more than half their length; capsule ovoid-triangular, 1.5-2.1 mm. long; columella 1.3-1.6 mm. long; seed ovoid-quadrangular, 1-1.4 mm. thick, the angles definite, larger (dorsal) 2 facets with 2 or 3 transverse sulci and low rounded ridges (not involving the angles), pale-brownish to whitish, ecarunculate. *Chamaesyce hyssopifolia* (L.) Small. Locally abundant in moist canyons in Trans-Pecos mts. (Brewster, El Paso, Jeff Davis and Presidio cos.), July-Oct.; Arg. n. to S.C., La., N.M. and Ariz.

35. *Euphorbia nutans* Lag. EYEBANE. Annual herb, in some areas to 1 m. tall; main stem erect, 2-5 mm. thick, only a few cm. long, giving way above to long erect or ascending pseudodichotomous branches distally, 1-4 mm. thick, distal internodes often crisply white-pubescent on one or two sides; leaves opposite; blades often with central splotch, oblong-lanceolate to oblong, often slightly curved or falcate, 8-35 mm. long, rounded or

acute at apex, inequilateral and rounded or truncate at base, marginally serrate, mostly glabrous above, usually pilose beneath at least at base; petioles 1-1.5 mm. long; stipules mostly united or at distal nodes distinct, triangular to subulate, 0.5-1 mm. long, lacerate or ciliate; cyathia solitary in the forks or in cymose clusters; involucre turbinate, 0.8-1.1 mm. long to bases of glands; glands 5, stalked, circular or slightly elliptic, 0.1-0.3 mm. in diameter; appendages obsolete or even a little longer than the gland is wide, entire or irregularly lobed; *staminate flowers* 5 to 11 per cyathium; *pistillate flower*: styles 3, bifid about half their length, 0.6-1 mm. long, yellowish; capsule ovoid-triangular, 1.9-2.3 mm. long; columella 1.8-2 mm. long; seed ovoid, 1.1-1.6 mm. long, 0.9-1.1 mm. thick, finely and irregularly wrinkled (with 5 to 9 faint wrinkles) or rippled, whitish to fuscous, ecarunculate. *Chamaesyce nutans* (Lag.) Small, *E. Preslii* Guss. Abundant nearly throughout (local in Plains Country and Trans-Pecos), May-Nov.; widespread in warmer parts of the world, in Am. n. to S.D., Minn., Mich., N.Y. and N.E.

In recent years many authors, through error, have applied the name *E. maculata* to this species. Reputedly poisonous.

36. *Euphorbia hypericifolia* L. Annual glabrous herb 1-5 dm. tall; main stem erect, 1-2 (-3) mm. thick, only a few cm. long, giving way above to the erect or ascending branches, pseudodichotomous distally, about 1 mm. thick; internodes glabrous; leaves opposite; blades oblong-lanceolate varying from oblong to oblong-spatulate or even lanceolate, 10-35 mm. long, marginally serrulate especially toward apex and on the lower margin, oblique and blunt at base, usually rounded at apex; petioles 1-1.5 mm. long; stipules distinct or united, deltoid, membranous, 1-2 mm. long, sometimes ciliate on the inner edge; cyathia strongly clustered in lateral and terminal nearly leafless stalked glomerules 5-10 mm. across; peduncles of the individual cyathia 0.4-2 (-4) mm. long; involucre obconical, 0.4-0.9 mm. across, glabrous; glands 5, subcircular, 0.05-0.2 mm. across; appendages white to purplish-white, rotund and usually thrice as wide as the larger glands, developing late and appearing absent on young cyathia; *staminate flowers* 2 to 20 per cyathium; *pistillate flowers*: styles 3, bifid to about their middle, about 0.4 mm. long; capsules ovoid, roundly triangular, about 1.3 mm. long; columella about 1.1 mm. long; seed ovoid, 0.9-1 mm. long, about 0.5 mm. thick, with slight irregular depressions separated by very low smooth ridges, brownish or reddish with a very thin whitish bloom. *Chamaesyce hypericifolia* (L.) Millsp., *C. glomerifera* Millsp. Locally abundant in extreme s. Tex. (Cameron and Hidalgo cos.), occasionally waifed in flower beds farther n. (Webb, Jefferson and Matagorda cos.), spring-fall; Venez. and Col., n. to Ga., Fla. and Tex.

37. *Euphorbia hirta* L. Taprooted pubescent annual; stems few, erect to decumbent, 2-60 cm. long, 1-1.5 mm. thick, strigose and (especially the distal internodes) commonly pilose with long yellowish tapering hairs; internodes 5-30 (-70) mm. long; leaf blades prevailing broadly rhombic-lanceolate, varying to narrowly lanceolate to ovate, 4-40 mm. long, above sparsely strigose and glabrate, below with appressed to spreading crisped hairs, at base strongly inequilateral, acute at apex, marginally sharply to bluntly serrate; petioles 1-2 mm. long; stipules deltoid, long and slenderly attenuate, about 1 mm. long, distinct, mostly with a few linear lobes near the base and with short scattered hairs; cyathia in dense stalked essentially leafless glomerules in the upper axils; involucre obconic-campanulate, 0.6-0.9 mm. thick, antrorsely strigose; glands 5, stipitate, cupuliform to patelliform, circular to transversely oval, 0.15-0.3 mm. thick; appendages white, glabrous, entire, small or often absent; *staminate flowers* 2 to 8 per cyathium; *pistillate flower*: ovary antrorsely short-strigose; styles 0.2-0.4 mm. long, bifid half to two thirds their length; capsule 1-1.2 mm. long, sharply 3-angled, widest below the middle; seeds ovoid, sharply quadrangular, 0.7-0.9 mm. long, 0.5-0.6 mm. thick, truncate basally, with subregular to quite irregular low smooth wrinkles, pale-brown. *Chamaesyce hirta* (L.) Millsp. Very rare as a waif in coastal s. Tex., not persistent, summer; widespread in the warmer parts of the world.

38. *Euphorbia pycnanthema* Engelm. Perennial herb (or some lasting only one season?) a few cm. tall; stems 5 to 50 from the crown, about 1 mm. thick, 5-35 cm. long, prostrate or ascending at the ends, tan to rubescent, closely and crisply white-pubescent, all sparingly branched; leaves opposite; blades ovate-oblong to ovate-lanceolate, (5-) 7-4 (-22) mm. long, at base very inequilateral and truncate or occasionally obscurely

cordate, at apex rounded or often acute with 40-90° angle, marginally mostly entire or the abaxial longer side with a few teeth, grayish-green to greenish-gray, clothed with short crisped whitish hairs or occasionally glabrous above; petioles 0.3-1 mm. long, purple to reddish-tan, with whitish hairs; stipules well-developed on both sides of stems at least at the distal nodes, distinct, lanceolate to subulate, usually unequally bifid or trifid and the finer division subulate, 0.8-1.2 mm. long, whitish to pinkish, submembranaceous, apparently deciduous; cyathia in dense cymose glomerules and a few of them borne singly in the penultimate forks; involucre turbinate to campanulate, 0.9-1.3 mm. long to base of glands, short white-hairy; glands 4, short-stalked or sessile, nearly round, reddish to dark-maroon; appendages white to pinkish-white, conspicuous, 1 or 2 times as long as the gland is wide, erose or irregularly crenate; *staminate flowers* 10 to 18 per cyathium; *pistillate flower*: styles 3, bifid more than half their length, the slender divisions occasionally clavellate; capsule oblong-ovoid, roundly triangular, 1.3-1.9 (-2) mm. long, longer than broad, shortly white-hairy; seed narrowly oblong-quadrangular, 1.1-1.4 mm. long, 0.6-0.8 mm. thick, acute apically, with faint low regular or irregular transverse wrinkles, brownish or whitish-brown, ecarunculate. *Chamaesyce pycnanthema* (Engelm.) Millsp. Local in Chih. Desert in s. Brewster Co. in the Trans-Pecos, Apr.-Nov.; Chih., Coah. and Tex.

Our plants are related to and have been considered conspecific with *E. capitellata* Engelm. of Ariz., Son. and Baja Calif.

39. *Euphorbia cinerascens* Engelm. Perennial herb; taproot woody, 1-8 mm. thick, dark-barked, sometimes branched; stems numerous, prostrate, 4-35 cm. long, somewhat branched, crisply white-strigillose; leaves opposite; blades ovate to ovate-elliptic or ovate-oblong, 2-9 mm. long, 2-6 mm. wide, obtuse at apex, slightly inequilateral and truncate or rounded at base, marginally entire, white-strigillose at least below, dark olive-green to almost canescent grayish-green; petioles about 1 mm. long; stipules dorsally united, ventrally distinct at least at distal nodes, 0.15-1.3 (-1.4) mm. long, lanceolate to subulate, densely white-strigillose; cyathia solitary at distal nodes or in forks; involucre turbinate, 0.8 mm. long to base of glands, whitish-strigillose; glands 4, round to oblong, 0.1-0.4 mm. long, flat to cupped, dark-purplish to cherry-red; appendages occasionally absent, usually developed but shorter than the gland is wide, white to purplish or cherry-red, marginally erose; *staminate flowers* 10 to 20 per cyathium; *pistillate flower*: styles 3, 0.2-0.4 (-0.8) mm. long, bifid to the base, cherry-red, the divisions terete to slightly clavellate; capsule ovoid, roundly triangular, 1.2-1.5 (-1.75) mm. long, white-strigose especially on the purple angles; columella 1.1-1.3 mm. long; seed oblong-quadrangular, 1-1.3 (-1.5) mm. long, 0.5-0.7 (-0.9) mm. thick, smooth, apically narrowed and acute, white to tawny-white, ecarunculate. *Chamaesyce cinerascens* (Engelm.) Small. Common on calcareous uplands and deserts in the Trans-Pecos (w. to Hudspeth Co.), w. Edwards Plateau and Rio Grande Plains (e. to Kimble and Duval cos.), Apr.-Nov.; S.L.P., Tam. and Chih. n. to Tex.

40. *Euphorbia serpyllifolia* Pers. Glabrous annual herb, 5-200 mm. tall; stems few to numerous, 0.5-1.5 mm. thick, usually prostrate (more commonly ascending on calcareous soils), 5-35 cm. long, much-branched, the branching occasionally pseudodichotomous distally, usually the distal internodes and occasionally the older ones "winged" (meaning flattened in the plane of the leaves with narrow decurrent buttresses); leaves opposite; blades very variable, usually oblong or obovate-oblong, often falcate or appearing bowed-in along the sides by revolution of the lateral margins, 3-12 (-17) mm. long, 2 to 4 (to 7) times as long as broad, proportionately narrower on calcareous soils, inequilateral at base, usually rounded at apex, marginally toothed at least toward the apex (use lens) and on the abaxial longer side toward the base often with an elongate median splotch; petioles slender, less than 1 mm. long; stipules relatively large and conspicuous, distinct, usually deeply bifid to trifid, the divisions subulate, membranaceous, 1.1-1.6 mm. long; cyathia solitary at the nodes and distal forks or appearing cymose-clustered by shortening of the distal internodes; involucre turbinate to narrowly campanulate, occasionally slightly urceolate, about 0.5 mm. long to base of glands; glands 4, sessile to short-stalked, oblong, 0.15-0.25 mm. long, cupped; appendages about as long as gland is wide or shorter, apron-shaped, marginally entire to crenulate or subdentate; *staminate flowers* 5 to 18 per cyathium; *pistillate flower*: styles 3, 0.2-0.5 mm. long,

merely notched or bifid less than a third their lengths; capsules ovoid-triangular, 1.5-1.9 mm. long; columella 1.3-1.6 mm. long; seed narrowly oblong-quadrangular, 1-1.4 mm. long, apically acute, smooth or with a few indistinct low rounded transverse wrinkles, tawny-white to sordid purplish-white to ochroleucous, ecarunculate. *Chamaesyce serpyllifolia* (Pers.) Small. Frequent in desert grasslands in the Trans-Pecos, infrequent to rare in Edwards Plateau e. to Edwards Co., July-Nov.; Jal. and Qro. n. to B.C., Alta., and Minn.; adv. in Eur. and S.A.

41. *Euphorbia glyptosperma* Engelm. Glabrous annual herb; stems 5 to 45, 0.5-1.5 mm. thick, prostrate, 5-33 cm. long, much-branched; branching occasionally pseudodichotomous distally; internodes not at all winged, a few aberrant specimens have lines of short hairs on the stems; leaves opposite; blades oblong, occasionally obovate-oblong or rarely ovate-oblong, 2-8 (-15) mm. long, usually (2 or) 3 or 4 (to 6) times as long as broad, often subfalcate by revolution of lateral margins, very inequilateral and rounded or truncate at base, marginally serrulate at least at the rounded apex (use strong lens) and often on the abaxial side toward the base; petioles about 0.3-1 mm. long; stipules glabrous, distinct, bifid or trifid, the divisions subulate, 0.3-1 mm. long, membranaceous; cyathia solitary at the distal nodes or in the forks; involucre turbinate, 0.4-0.6 mm. long to base of glands; glands 4, minute, short-stalked to sessile, oblong to almost rotund, about 0.1 mm. long, cupped; appendages apron-shaped, usually shorter than gland is wide or even occasionally obsolete, entire to erose or subcrenate; *staminate flowers* 1 to 5, usually only 4, per cyathium; *pistillate flower*: styles 3, 0.15-0.3 mm. long, bifid about a third to half their length, the terete divisions occasionally subclavellate; capsule ovoid-triangular, 1.4-1.7 mm. long; columella 1.2-1.4 mm. long; seed oblong-quadrangular, 1-1.3 mm. long, 1.7-1.9 mm. thick, apically acute, all facets traversed by 4 to 6 (to 8) definite transverse ridges occasionally anastomosing but usually distinct and regular and usually somewhat involving the four definite angles, tawny with thick white coat, ecarunculate. *Chamaesyce glyptosperma* (Engelm.) Small. Frequent over much of Tex. (rare in extreme e.), June-Sept.; widespread in N.A.

42. *Euphorbia theriaca* Wheeler. Glabrous annual herb; stems 5 to 40, prostrate or ascending, 5-30 cm. long, 0.3-1.5 mm. thick, flexuous or rarely zigzag, much-branched (distal branching occasionally pseudodichotomous); leaves opposite; blades oblong-orbicular or shortly ovate to obovate or shortly oblong, 2-5.5 mm. long, about 1 to 2.2 (to 2.7) times as long as broad, at apex rounded or truncate, occasionally emarginate, at base rounded, marginally entire; petioles 0.7-1.2 mm. long; stipules glabrous, 0.7-1 mm. long, on lower side usually united into an entire or shortly bifid scale, on upper side usually distinct, subulate, entire; cyathia solitary at the distal nodes; involucre campanulate or hemispheric, occasionally suburceolate, 0.9-1.5 mm. long to base of glands; glands 4, sessile or short-stalked, nearly round or slightly elliptic, 0.3-0.6 (-0.7) mm. long; appendages absent or present, white, semilunate or bib-shaped, essentially entire, narrower than the diameter of the gland; *staminate flowers* (15 to) 23 to 36 per cyathium; *pistillate flower*: styles 3, 0.3-0.4 mm. long, bifid about half their length, the divisions clavellate; capsule ovoid, roundly and rather deeply 3-lobed or merely triangular in some specimens, 1.1-1.6 mm. long, 1.5-1.7 mm. broad; columella 1-1.3 mm. long; seed oblong-quadrangular, 1-1.2 mm. long, 0.7-0.8 mm. thick, acute apically, rounded or truncate basally, the facets convex with 2 to 4 very definite high rounded transverse ridges meeting the ridged angles, tawny with whitish seed coat, ecarunculate. *Chamaesyce theriaca* (Wheeler) Shinn. Locally abundant in deserts, s. Brewster and Presidio cos. in the Trans-Pecos, July-Oct.; Tex., Chih. and Coah.

The Brewster Co. specimens have suborbicular dark-green leaves with slender contorted petioles, exappendiculate glands and capsules that are deeply and roundly 3-lobed in transection. The Presidio Co. specimens have shortly oblong, yellow-green leaves, appendiculate glands and capsules which are triangular in transection.

43. *Euphorbia Golondrina* Wheeler. Glabrous annual herb; stems several, prostrate, 5-35 cm. long, 0.7-1.5 mm. thick, occasionally zigzag below with slenderer branches at the nodes, distally more normally pseudodichotomous; leaves opposite; blades oblong or ovate-oblong to narrowly elliptic-oblong or even almost orbicular, 5-10 mm. long, inequilateral and rounded at base, rounded at apex, marginally entire; petioles 1-1.7 (-2) mm. long; stipules on lower side of stem single (united), subulate, bifid, occasionally with a

few minute hairs near the tip, those on upper side of stem distinct and subulate; cyathia solitary at the nodes and in the forks; involucre shortly rounded, slightly urceolate, 0.9-1 mm. long to base of glands; glands 4, remote, stalked, erect, round, 0.15-0.5 mm. in diameter, cupped; appendages sometimes obsolete, usually slightly developed, white, semilunate, narrower than the gland; *staminate flowers* 28 to 40 per cyathium (reportedly 39 to 50 in the type specimen); *pistillate flower*: styles 3, ochroleucous, 0.2-0.3 (-0.4) mm. long, notched or bifid; capsule ovoid-triangular, 1.8-2 mm. long, green; columella 1.7-1.8 mm. long; seed narrowly oblong-quadrangular or occasionally the 2 ventral facets almost plane, 1.7-1.8 mm. long, about 0.8 mm. thick (when moistened 1.8-1.9 mm. long and about 1 mm. thick), apically acute, tawny-white with thick white hydrophilous "coat," smooth or with 6 to 8 very faint low rounded transverse wrinkles on the ventral facets, ecarunculate. *Chamaesyce Golondrina* (Wheeler) Shinn. Local in alluvial or eolian soil, deserts of s. Brewster Co., Tex., July-Oct.; endemic.

44. *Euphorbia micromera* Engelm. Mostly glabrous annual herb; stems 5 to 40, prostrate, 5-22 cm. long, 0.1-1.5 mm. thick, usually not markedly zigzag, much-branched, the distal branching occasionally pseudodichotomous; leaves opposite; blades ovate-oblong to ovate-elliptic, 2-5 mm. long, 1-2.7 mm. broad, usually less than twice as long as broad, very inequilateral and truncate at base, rounded at apex, marginally entire, greenish, rather firm, occasionally almost appearing dimorphic because of reduction in size at the floriferous nodes; petioles 0.2-0.8 mm. long; stipules 0.4-0.6 mm. long, subulate, distinct on upper side of stem, approximate or united on lower side at least at the distal nodes, distinctly short-ciliate at least at the tip; cyathia solitary at the distal nodes and forks; involucre campanulate, sometimes suburceolate, 0.4-0.5 mm. long to base of glands; glands 4, remote (the minutely ciliate subulate lobes of the involucre clearly visible between them), short-stalked, often erect, nearly round, 0.05-0.15 mm. in diameter, flat or faintly cupped; appendages absent; *staminate flowers* 2 to 5 per cyathium (usually exactly 5); *pistillate flower*: styles 3, 0.1-0.2 mm. long, stout and rigid, pinkish to purplish-white, notched or bifid, the divisions shortly clavellate; capsule ovoid-oblong, roundly triangular, 1.2-1.4 mm. long, about as broad; columella 1-1.2 mm. long; seed narrowly oblong-quadrangular, 0.8-1.1 mm. long, about 0.5 mm. thick, acute at apex, essentially smooth or with very faint irregular wrinkles, tawny with thick white hydrophilic coat, ecarunculate. *Chamaesyce micromera* (Engelm.) Woot. & Standl. Infrequent in sandy deserts in the Trans-Pecos (common near El Paso), Aug.-Oct.; Ut., Calif. and N.M., s. to Chih. and Coah.

45. *Euphorbia simulans* (Wheeler) Warnock & M. C. Johnst. Glabrous perennial herb (or occasionally behaving as a winter annual?) 1-12 cm. tall; stems 10 to 25, 7-32 cm. long, 0.4-2 mm. thick, usually prostrate, occasionally ascending, buttressed at the nodes, greenish to dark-purple or reddish or almost black, usually distinctly zigzag from node to node with more slender secondary branches at each node complementary to the main ones or distally the branching occasionally pseudodichotomous; leaves opposite; blades shortly oblong, 2-4 (-5) mm. long, usually about 1 to 1.7 times as long as broad, very inequilateral and truncate or rounded at base, truncate or rounded at apex, occasionally emarginate, marginally entire, firm and a little thickened; leaves at the distal floriferous nodes somewhat reduced, the foliage almost dimorphic at times; petioles 0.8-1.6 mm. long; stipules united on lower side of stem into a single lanceolate bifid structure, the divisions subulate, ochroleucous to pale-purple, sometimes minutely ciliate near the tips; stipules on upper side of stem (at least at the floriferous nodes), distinct, each subulate, whitish to purplish, occasionally minutely ciliate toward the tip, with a definite zone of abscission sometimes visible at the base, deciduous, 0.5-0.8 mm. long; cyathia solitary at the distal nodes or in the forks; involucre campanulate, 0.8-1.2 mm. long to base of glands; glands 4, approximate, sessile or nearly so, rotundly oblong, about 0.5 mm. long, nearly flat or folded; appendages absent; *staminate flowers* 15 to 32 per cyathium; *pistillate flower*: styles 3, stout, 0.2-0.3 mm. long, bifid two thirds their length, the usually erect divisions firm and terete; capsule ovoid, roundly triangular, 1.5-1.7 mm. long, about as broad, columella 1.2-1.5 mm. long; seed oblong, roundly quadrangular, 1.1-1.3 mm. long, apically acute, with 6 to 8 very faint low rounded transverse regular or irregular wrinkles especially visible on the ventral facets, tawny with thick white coat, ecarunculate. *E. polycarpa* Benth. var. *simulans* Wheeler, *Chamaesyce polycarpa* (Benth.) Parish var. *simulans* (Wheeler) Shinn. Locally abundant in sandy and rocky deserts, s.

Brewster and s. Presidio cos. in the Trans-Pecos, Apr.-Oct., rarely Dec., Feb.; endemic.

46. *Euphorbia perennans* (Shinners) Warnock & M. C. Johnst. Glabrous perennial herb, 13-47 cm. tall; taproot 3-10 mm. thick, woody; stems 5 to 20, 0.5-3 mm. thick, erect, pseudodichotomously branched; herbage somewhat glaucous; leaves opposite; blades rather firm, rather variable in shape, the older ones usually ovate-deltoid to nearly orbicular and the ones at the floriferous nodes relatively narrower and usually ovate or ovate-elliptic, at apex rounded, at base rounded to truncate or even cordate, marginally entire, 5-17 mm. long, 4-16 mm. wide, often nearly as broad as long; venation in some specimens evident, showing 5 to 7 veins from the base, with the midvein much the most prominent; petioles 0.8-2 mm. long; stipules usually approximate but distinct on "lower" side of stem, usually united above into a single linear bifid structure, the subulate divisions 0.4-0.7 mm. long; cyathia solitary in the forks; involucre campanulate to hemispheric, often very slightly urceolate, 1.5-2.2 mm. long to base of glands; glands 4, short-stalked or usually sessile, erect, elliptic to oblong, distinctly cupped, 0.7-1 mm. long; appendages absent; *staminate flowers* 35 to 45 per cyathium; *pistillate flower*: styles 3, 0.7-1.1 mm. long, curved and spreading when young, becoming erect with age, bifid about half their length, the rather stout divisions terete; capsule ovoid-triangular, 3-3.3 mm. long; columella 2.7-2.8 mm. long; seed oblong-triangular or subquadrangular (the ventral facets almost parallel and plane), 2.2-2.4 mm. long, acute at apex, rounded at base, essentially smooth or only with faint irregular wrinkles, the ventral facets slightly concave, whitish or pinkish with a thick white hydrophilic (mucilaginous) coat, ecarunculate. *Chamaesyce perennans* Shinners. Deserts of s.w. Brewster Co. (Terlingua-Lajitas areas), July-Sept.; endemic.

47. *Euphorbia Fendleri* T.&G. Glabrous low perennial herb; taproot woody; stems many, slender, to about 15 cm. long, often pseudodichotomously branched; leaves opposite; blades acute at apex, inequilateral at base, marginally entire, rather firm, occasionally glaucous, occasionally reticulate-veiny; petioles 0.5-1 mm. long; stipules approximate or sometimes united into a bifid structure or at the floriferous nodes distinct, subulate, 0.5-1 mm. long, occasionally lacerate along the margins near the tip with the divisions hairlike; cyathia solitary at the nodes or in the forks; involucre turbinate to campanulate, 1.2-1.8 mm. long to base of glands; glands 4, usually quite sessile, oblong, 0.4-1 mm. long, more or less cupped, with or without appendages; *staminate flowers* 8 to 35 per cyathium; *pistillate flowers*: styles 3, 0.3-0.7 mm. long, bifid at least half their length, the divisions terete and occasionally slightly clavellate; capsule ovoid-triangular, some plumply so, mostly less than 2.2 mm. long; columella 1.6-1.9 mm. long; seed oblong-quadrangular (or the ventral facets sometimes almost parallel, making it triangular), the angles rounded or at least obtuse, acute at apex, truncate at base, essentially smooth or with a few faint irregular wrinkles, pale pinkish-brown to tawny with a white coat, ecarunculate. *Chamaesyce Fendleri* (T. & G.) Small. Widespread in the western drier half of the state and represented with us by three varieties, as follows:

Var. *Fendleri*. Taproot usually 1.5-3 mm. thick, the crown often buried along with the basal parts of the many stems which are all annual, 0.1-0.3 mm. thick and decumbent; leaf blades ovate, 1 or 2 times as long as broad, 2-6 mm. long, at base truncate to rounded or slightly cordate; glands purplish-green to reddish-brown; appendages absent or obtuse and shorter than the gland is wide; staminate flowers 15 to 22 per cyathium; anthers ochroleucous; capsule 1.9-2.1 mm. long; seed 1.4-1.8 mm. long. Frequent in calcareous or sandy soil in the w. half of Tex., e. to n.-cen. Tex. and caliche cuerdas of the Rio Grande Plains, Apr.-Sept.; Okla. and Kan. to Wyo. and Ut., s. to Tex.

Var. *chaetocalyx* Boiss. Taproot 3-9 mm. thick at summit; crown usually aerial; some stems basally persisting and perennial, often thicker than 0.3 mm. at least basally, erect or ascending; leaf blades ovate-lanceolate to linear-lanceolate, 6-11 mm. long, 3 or 4 (to 6) times as long as broad, basally acute to truncate; appendages lanceolate or deltoid, 1 to 3 times as long as the gland is broad, sometimes bifid or coarsely crenate; staminate flowers 8 to 20 per cyathium; anthers yellowish or ochroleucous; capsule 2-2.3 mm. long; seed 1.8-2 mm. long. *E. chaetocalyx* (Boiss.) Tidestr., *Chamaesyce chaetocalyx* (Boiss.) Woot. & Standl., *C. Fendleri* var. *chaetocalyx* (Boiss.) Shinners. Frequent in dry calcareous soils of desert mts. in the Trans-Pecos, Apr.-Sept.; Tex. and N.M. w. to Ariz. and Calif.

Var. *triligulata* Wheeler. Taproot 8-15 mm. thick at summit; crown usually aerial; stems at least basally often perennial and suffrutescent and becoming woody with a gray minutely longitudinally fissured bark, the stems basally thicker than 0.3 mm. and ascending; leaf blades lanceolate to linear-lanceolate, 3-6 mm. long, 3 or 4 (to 6) times as long as broad, basally acute to truncate; glands usually bright-green; appendages longer than the gland is broad, parted to the base into 3 to 5 linear-subulate white lobes 0.5-1.5 mm. long; staminate flowers 22 to 35 per cyathium; anthers violet; capsule 1.8-2.1 mm. long. *Chamaesyce Fendleri* var. *triligulata* (Wheeler) Shinn. Rare, known only from limestone cliffs above Boquillas Canyon, s. Brewster Co. in the Trans-Pecos, July-Sept.

48. *Euphorbia jejuna* Warnock & M. C. Johnst. Glabrous low perennial herb; taproot 3-14 mm. thick, dark-barked; stems 20 to 60 from the woody crown, annual, decumbent, 1-9 cm. long, 0.2-1.1 mm. thick, often flexuous, much-branched, the branching often pseudodichotomous or even whorled with several leaves and branches emerging at a single node; leaves opposite; blades rotundly obovate or ovate or nearly elliptical, 3-6 (-8) mm. long, 1 to 1.5 times longer than broad, at apex rounded or angled (90°-180°), at base shortly rounded or truncate and inequilateral, marginally entire, rarely glaucous, occasionally reticulate-veined; petioles 0.7-1 mm. long; stipules on both sides of stems united into a very short scale which is lacerate to lacinate or rarely bifid, firm, lanceolate or muticous-deltoid, less than 1 mm. long, not conspicuous without a strong lens, or at floriferous nodes stipules rarely separate and each lanceolate on the upper side of the stem; cyathia solitary at the upper nodes in the forks; peduncles 0.9-2 mm. long; involucre hemispheric or broadly campanulate, 1.2-1.5 mm. long to the base of the glands; glands 4, subequal, oblong, about 1.6 mm. long, cupped; appendages conspicuous, erect or spreading, white, about 0.6 mm. long, rarely entire or merely crenate, usually deeply dissected into 4 or 5 acute or acuminate lobes or even parted nearly to the base into 4 to 6 distinct segments, the form rather variable even on a single individual; *staminate flowers* 12 to 25 per cyathium; *pistillate flower*: styles 3, about 0.5 mm. long, entire (not bifid), thickly round-capitate; capsule ovoid, plumply triangular, olive-green, 1.8-2.2 (-2.7) mm. long; columella 1.7-2 (-2.3) mm. long; seed oblong, angled, 1.6-2 (-2.3) mm. long, apically narrowed and acute, the facets with faint irregular transverse wrinkles or with up to 10 or 11 faint but definite low rounded transverse ridges, pale-brownish or tawny-pink with a thick white coat, ecarunculate. Rare and local in calcareous soils in the Trans-Pecos, Edwards Plateau and Plains Country (Brewster, Mitchell, Nolan, Terrell and Val Verde cos.), Mar.-May; endemic.

49. *Euphorbia astyla* Boiss. Glabrous low perennial herb; root 5-12 mm. thick; stems several to many from the crown, succulent (wrinkled upon drying), 0.7-1.2 mm. thick, 4-23 cm. long, prostrate; leaves opposite, essentially sessile; blades orbicular-reniform to deltoid-oblong, 2-8 mm. long, almost as broad, rounded or truncate at apex, cordate to clasping and inequilateral at base, marginally entire, green to somewhat glaucous, firm; stipules on both sides of the stem united into a white scale about 0.2 mm. long, wider, erose or minutely lacerate and sometimes fringed; cyathia solitary at the most distal nodes; involucre hemispheric to broadly campanulate, about 1.2 mm. long to base of glands, wider; glands 4, shallowly cupped, oblong, about 0.5 mm. long; appendages entire, shorter than the gland is wide, forming a narrow margin; *staminate flowers* 22 to 26 per cyathium; *pistillate flower*: styles 3, 0.2-0.3 mm. long, entire (not bifid), the ends thickly round-capitate; capsule ovoid, plumply triangular, 1.9-2.6 mm. long; columella 1.8 mm. long; seed oblong-quadrangular, 1.5-1.7 mm. long, 0.8-1 mm. thick, apically subacute, basally subrounded, with low irregularly anastomosing transverse ridges separated by narrow grooves, the angles often notched at these grooves, the thick coat white and mucilaginous, obscuring any deeper coloration, ecarunculate. *Chamaesyce astyla* (Engelm.) Millsp. Rare in low calcareous areas, perhaps alkaline soils, in the Trans-Pecos (Pecos Co. only), summer; Coah., Dgo. and Tex.

50. *Euphorbia albomarginata* T.&G. Glabrous low perennial herb; taproot woody in age, to 3-4 mm. thick; stems several to many, 0.5-1.5 mm. thick, some of the older ones persistent and perennial and becoming dark-barked, mostly annual, 10-35 cm. long, usually quite prostrate, often rooting at the nodes, often flexuous, much-branched, the branching often pseudodichotomous; leaves opposite; blades orbicular to oblong, 3-8 mm. long, almost as broad, rounded at apex, occasionally emarginate or apiculate, strongly inequilateral and rounded at base, marginally entire; petioles 0.5-1.2 mm. long; stipules on both sides of stem united into a white membranous deltoid to acuminate lanceolate

scale 1-2 mm. long and entire to lacerate or erose; cyathia solitary at the nodes and in the forks; involucre turbinate, about 1 mm. long to the base of the glands; glands 4, shallowly cupped, oblong, 0.5-1 mm. long; appendages usually conspicuous, white, 1 to 3 times as long as gland is wide, entire to erose; *staminate flowers* 15 to 30 per cyathium; *pistillate flower*: styles 3, 0.5-0.7 mm. long, bifid nearly their entire lengths, the divisions slender; capsule ovoid, sharply triangular, 1.3-2 mm. long; columella 1-1.3 mm. long; seed oblong-quadrangular (or the ventral facets nearly parallel), 1.2-1.7 mm. long, 0.7-0.9 mm. thick, apically acute, basally truncate, essentially smooth or minutely punctulate in transverse lines, pale-brown with a white coat. *Chamaesyce albomarginata* (T. & G.) Small. Widespread in w. and s. halves of Tex., usually in poorly drained clay soil, Apr.-Sept.; Okla., N.M. and Nev. s. to Sin., Dgo. and Tam.

51. *Euphorbia serpens* H.B.K. **HIERBA DE LA COLONDRINA**. Glabrous annual herb (or occasionally winter annuals or over-wintering?); stems numerous, 0.1-1.1 mm. thick, 5-20 (-50) cm. long, prostrate, often rooting at the nodes, often flexuous, much-branched, the branching occasionally pseudodichotomous distally; leaves opposite; blades ovate-orbicular or broadly oblong to orbicular, 2.7 mm. long, almost or quite as broad; rounded at apex, rounded and somewhat inequilateral at base, marginally entire; petioles about 0.5 mm. long; stipules on both sides of stem united into a white to pink membranous scale 0.2-1.2 mm. long and entire to erose or lacerate; cyathia solitary at the nodes and in the forks; involucre urceolate-turbinate, about 0.7 mm. long to base of glands; glands 4, oblong, short-stalked, about 0.1 mm. long, cupped; appendages about as long as the glands are wide, marginally erose, sometimes obsolete; *staminate flowers* 3 to 8 (to 10) per cyathium; *pistillate flower*: styles 3, about 0.5 mm. long, notched; capsule ovoid-oblong, triangular, 1-1.2 mm. long; columella about 1 mm. long; seed narrowly oblong, quadrangular, sometimes roundly so, 0.7-0.9 mm. long, apically acute, essentially smooth, brownish with white coat, ecarunculate, the ventral facets slightly concave. *Chamaesyce serpens* (H.B.K.) Small. Usually in calcareous soils, throughout Tex. but less frequent in the w. half, Mar.-Nov.; widespread in trop. and temp. Am. n. to Ont., O., Ind., N.M. and Ariz.

52. *Euphorbia cordifolia* Ell. Glabrous taprooted annual; stems numerous, prostrate, (4-) 15-60 cm. long; leaf blades elliptic-orbicular to oblong and ovate-oblong, 4-12 mm. long, more or less inequilateral and often cordate at base, marginally entire; petioles about 1 mm. long; stipules parted to the base into few to several filiform segments to 1.4 mm. long, mostly with short scattered hairs at least when young, the dorsal ones distinct, the ventral ones often united; peduncles 0.4-4 mm. long; cyathia solitary at the nodes and at the branch tips but often congested by the marked shortening of the upper internodes; involucre broadly campanulate, 1.3-1.6 mm. across; glands transversely elliptical to oblong, often strongly folded, 0.5-0.9 mm. long; appendages 1 to 3 times as long as the gland is high, to 1.3 mm., the wider ones radially broadly elliptical to reniform, glabrous, entire or with 2 or 3 low blunt teeth; *staminate flowers* 29 to 44 per cyathium; *pistillate flower*: styles bifid to the base, 0.6-0.9 mm. long; capsule glabrous, sharply 3-angled, wider below the equator, 1.7-2.1 mm. long; seeds ovoid-triangular, 1.2-1.5 mm. long, 0.7-0.9 mm. broad and thick, ovate to oblong-ovate, usually acute, with low faint wrinkles, slightly concave to slightly convex, the angles blunt and the coat white, micro-reticulate. *Chamaesyce cordifolia* (Ell.) Small. Frequent in openings on sandy soil, e. and s.e. Tex., s.w. in sand stringers to Atascosa Co. and s. near the coast to Cameron Co., summer-fall; Coastal States, N.C. to Tex.

53. *Euphorbia setiloba* Engelm. Pubescent annual herb; stems several, 0.5-1.1 mm. thick, 5-20 cm. long, prostrate, profusely branched (occasionally pseudodichotomously but usually unequally), the larger ("main") stems appearing zigzag, villous with long white trichomes; leaves opposite; blades oblong or orbicular to rarely oblong-ovate, 2-7 mm. long, 1 to 2 times longer than broad, rounded at apex, rounded and very inequilateral at base, marginally entire, villous like the stems but less densely so on upper surface; petioles 0.5-1 mm. long; stipules distinct, 0.1-1.2 mm. long, subulate and hairlike, caducous; cyathia solitary at the distal nodes; involucre slenderly urceolate, 1-1.3 mm. long to base of glands; glands 4, oblong, 0.2 mm. long, shallowly cupped, erect; appendages white to pink, much larger than the glands, 0.5-0.8 mm. long, parted at least half their lengths into 3 to 6 lanceolate acuminate lobes; *staminate flowers* 3 to 7 per cyathium; *pistillate flower*: styles 3, 0.2-0.3 mm. long, bifid about half their length, the divisions

slender; capsule ovoid-triangular, 1.1-1.4 mm. long, villous; columella 1-1.2 mm. long; seed oblong-triangular or quadrangular (the ventral facets variously forming a dihedral angle or nearly parallel), 0.9-1.1 mm. long, apically acute, basally truncate, sharply angled, essentially smooth or with very faint rounded irregular wrinkles, tawny with a thin white coat, ecarunculate. *Chamaesyce setiloba* (Engelm.) Millsp. Gravelly and sandy desert plains, s. Brewster Co. in the Trans-Pecos, Aug.-Sept.; N.M. w. to Calif., s. to Sin., Baja Calif; also Tex.

54. *Euphorbia arizonica* Engelm. Pubescent low perennial herb (occasionally behaving as winter annuals^p); taproots 1-5 mm. thick; stems several to many, 0.3-2 mm. thick, 7-30 (-40) cm. long, decumbent to ascending, densely pubescent with fine spreading translucent clavellate hairs, much-branched, the branches alternate and slender and often flexuous or rarely approaching the pseudodichotomous condition; leaves opposite; blades deltoid-ovate to ovate or the uppermost (smallest) ovate-oblong, 1-10 mm. long, 1.2 to 2 times as long as broad, rounded at apex, rounded and inequilateral at base, marginally entire, often slightly revolute, pubescent like the stems but less densely so on upper surface; petioles 1-2 mm. long; stipules minute, not visible without a strong lens, the lower united, the upper distinct; cyathia solitary at the nodes and in the forks; involucre narrowly cylindrical and urceolate, 1-1.5 mm. long to base of glands, pubescent with fine spreading white hairs; glands 4, shortly oblong, cupped, very small; appendages much larger than the glands, flabellate, 2 to 4 times as long as the glands (thus to 1 mm. long), spreading, usually entire marginally; *staminate flowers* 5 to 15 per cyathium; *pistillate flower*: styles 3, 0.5 mm. long, bifid less than half their lengths, the divisions slender; capsule ovoid, roundly triangular or sometimes widest at the middle, about 1.5 mm. long and about as broad, villous with clavellate hairs; columella about 1 mm. long; seed oblong or ovoid-quadrangular, 1-1.2 mm. long and about 0.6 mm. thick, apically acute, the facets traversed by rounded irregularly anastomosing transverse ridges separated by narrow grooves, the angles thus slightly crenulate, orangish with whitish bloom, ecarunculate. *Chamaesyce arizonica* (Engelm.) Arthur. Locally common in deserts of Brewster and Presidio cos. in the Trans-Pecos, July-Dec.; Tex. w. to Calif. and Baja Calif. and s.w. to Chih. and Dgo.

55. *Euphorbia villifera* Scheele. Pubescent or rarely glabrous perennial herb (flowering the first year), 5-25 cm. tall; stems few to many from the crown, 0.2-2 mm. thick, a few persistent at the base and becoming woody but these only about 1-2 cm. long, most of the stems annual and ascending or erect, 5-25 cm. long (or perhaps at times even longer), pilose with long white tapering hairs (rarely glabrous), pseudodichotomously much-branched; leaves opposite; blades ovate to ovate-oblong or the youngest ones sometimes ovate-deltoid, (3-) 5-8 (-10) mm. long, 1.2 to 2 times as long as broad, rounded or rarely subacute at apex, truncate and strongly inequilateral at base, marginally toothed at least on the distal half around the apex, beset with some very thin white spreading hairs 0.8-1.2 mm. long, at least near the margin on the lower surface and very sparse elsewhere; petioles slender, 0.5-1.7 mm. long; stipules united at the nonfloriferous nodes and distinct at the floriferous ones on both sides of the stem, at the nonfloriferous nodes forming an acuminate-deltoid scale which is serrulate or laciniate along the margins and about 1 mm. long, at the floriferous nodes narrowly deltoid-acuminate and serrulate or laciniate marginally and about 0.5 mm. long; cyathia solitary in the forks; involucre campanulate, sometimes narrowly so, 0.8-1.1 mm. long to the base of the glands, glabrous; glands 4, elliptical to nearly orbicular or oblong, 0.2-0.4 mm. long, cupped, erect, sessile or short-stalked; appendages 1 or 2 (to 4) times as long as the gland is wide and considerably wider than long, spreading or nearly erect, marginally entire; *staminate flowers* 9 to 23 per cyathium; *pistillate flower*: ovary deeply 3-lobed, quite glabrous and broader than long; styles 3, 0.4-0.6 (-0.7?) mm. long, bifid half to two thirds their length, the divisions spreading and terete; capsule 1.3-1.9 (-2.1) mm. long, broader than long, deeply 3-lobed, glabrous, the lobes oblong or occasionally narrowly deltoid; columella 1.1-1.5 mm. long; seed elongate-ovoid and rounded-quadrangular, 1-1.3 mm. long, 0.7-1 mm. thick, apically obtuse, essentially smooth, orange or ochraceous with thick white coat, ecarunculate. Incl. var. *nuda* Engelm., *Chamaesyce villifera* (Scheele) Small. Dry uplands, Trans-Pecos and Edwards Plateau e. to Bell and Travis cos., May-Oct.; Tex. s. and s.e. to Guat. and Yuc.

The diverse plants included here need much further analysis; possibly more than one species is represented.

56. *Euphorbia serrula* Engelm. Low annual herb; stems few to many, 0.5-1.5 mm. thick, prostrate, 5-25 cm. long, pilose with spreading hairs about as long as the stem is thick or longer, repeatedly pseudodichotomously branched; leaves opposite; blades oblong to slightly ovate- or obovate-oblong, 3-11 mm. long, 1.3 to 3 (to 4) times as long as broad, rounded at apex, very inequilateral and truncate at base, marginally sharply serrulate at least apically and on the abaxial margin, often with a median splotch, often falcate or at least appearing so by revolution of the lateral margins, pilose but more sparsely so than the stems or even glabrate; petioles 0.5-1.2 mm. long; stipules distinct, glabrous to rarely ciliate, deltoid, marginally fimbriate, 0.5-1.2 mm. long; cyathia solitary in the forks; involucre shortly campanulate, 0.5-1 mm. long to base of glands, mostly glabrous; glands 4, oblong to nearly round, 0.1-0.2 mm. long; appendages 1 to 4 times as long as the gland is wide, rounded, marginally entire to erose, spreading to erect; *staminate flowers* 7 to 13 per cyathium; *pistillate flower*: styles 3, 0.3-0.4 mm. long, bifid half to all their length, the divisions clavellate to terete; capsule broadly ovoid, plumply triangular, 1.9-2.2 mm. long, 3-3.5 mm. broad, truncate basally, glabrous; columella 1.7-1.9 mm. long; seed oblong, plumply quadrangular, 1.4-1.5 mm. long, about 1 (-1.5) mm. thick, angles sharp except the raphal one, apically acute, basally rounded to truncate, superficially smooth or porous like unglazed pottery, chalky-white to grayish-white, ecarunculate. *Chamaesyce serrula* (Engelm.) Woot. & Standl. Abundant in calcareous deserts in the Trans-Pecos, June-Sept.; Tex. to N.M., Ariz., Zac., Dgo. and Coah.

57. *Euphorbia indivisa* (Engelm.) Tidestr. Annual herb; stems several, 0.5-1 mm. thick, prostrate, 5-15 (-25) cm. long, crisply villous or basally glabrate, sparingly branched; branching unequally pseudodichotomous; leaves opposite; blades ovate-deltoid to oblong, 5-8 (-13) mm. long, 1.5 to 2 times as long as broad, acute at apex, very inequilateral at base, often falcate by the bowing inward of the abaxial margin, marginally serrulate, mostly glabrous above, sparsely crisply villous beneath or glabrate; petioles about 1 mm. long; stipules distinct, larger and more conspicuous on the lower side of the stem, subulate, 1-1.7 mm. long, usually entire or on the lower side of stem usually trifid with the middle lobe longest, crisply pubescent or the margin fimbriate; cyathia solitary at the distal nodes, often clustered by shortening of distal internodes; involucre narrowly campanulate or subcylindric, about 1 mm. long to base of glands; glands 4, oblong, cupped, erect, the 2 near the sinus 0.4-0.6 mm. long, the 2 distal ones 0.2-0.3 mm. long; appendages white to red to purple, on the distal glands symmetrical and only about 0.2 mm. long, on the proximal glands very asymmetrical and distended 1.1-1.4 mm. toward and beyond the glands, the margins erose or nearly entire; *staminate flowers* 5 to 15 per cyathium; *pistillate flower*: styles 3, essentially entire, 0.7-1.3 mm. long; terete; capsule ovoid-triangular or more deeply 3-lobed, 1.4-1.6 mm. long, truncate basally, strigose; columella 1.2-1.4 mm. long; seed oblong-quadrangular, 0.9-1.2 mm. long, 0.4-0.6 mm. thick, apically acute, basally truncate, with 3 to 5 transverse ridges separated by deep sharp grooves somewhat involving the angles, pale pinkish-brown with white coat, ecarunculate. *Chamaesyce indivisa* (Engelm.) Millsp. Grasslands on soil derived from dark basic igneous rocks, 4,500-6,500 ft. elev. in the Trans-Pecos, July-Aug. (-Sept.); Tex., N.M., Ariz., s. to Jal. and S.L.P.

58. *Euphorbia maculata* L. Low pubescent annual herb; stems several, usually prostrate or decumbent, mostly shaggy pubescent (villous) or glabrate basally, 10-45 cm. long; leaves opposite; blades elliptic-ovate or oblong-ovate to linear-oblong, 4-17 mm. long, apically various, basally inequilateral and truncate, marginally serrulate to subentire, sparsely villous, less densely so to glabrate above; petioles 1-1.5 mm. long, pubescent like the stem; stipules present, usually deltoid, acuminate, 1-1.5 mm. long, usually 2- or 3-parted, villous; cyathia solitary at the distal nodes but clustered by shortening of the distal internodes; involucre turbinate, about 0.8 mm. long to base of glands, villous; glands 4, oblong and very small; appendages short, white, irregularly crenate; *staminate flowers* 2 to 5 per cyathium; *pistillate flower*: styles 3, 0.3-0.4 mm. long, bifid a fourth to a third their length, the divisions clavellate; capsule ovoid-triangular, strigose, about 1.4 mm. long; columella slender, about 1.2 mm. long; seed oblong-quadrangular, about 1 mm. long, the facets with subregular low transverse ridges often slightly including the angles,

pale-brownish with white coat, ecarunculate. *E. supina* Raf., *Chamaesyce maculata* (L.) Small, *C. supina* (Raf.) Raf. In a variety of soils (commoner in disturbed sandy areas) e. of the Trans-Pecos, rare in the higher parts of the Plains Country and in the Edwards Plateau, summer-fall; throughout e. U.S.; adv. in Calif., Ore. and Eur.

59. *Euphorbia humistrata* Gray. Exceedingly similar to *E. maculata* but tending to root at the lower nodes and having bifid styles almost half as long as the capsule. *Chamaesyce humistrata* (Gray.) Small. Rare in disturbed sandy soil, e. and s.e. Tex. (Angelina, Bowie and Harris cos.), summer-fall; O., Ill. and Kan., s. to Ala., La. and Tex.

60. *Euphorbia stictospora* Engelm. Low annual pubescent herb; stems several, 0.8-1.5 (-3.5) mm. thick, prostrate, 5-25 (-35) cm. long, crisply villous, branching sparse to profuse, not pseudodichotomous, mostly consisting of many very short floriferous laterals with internodes only 1-3 mm. long; leaves opposite; blades shortly oblong to nearly orbicular or even oblong-obovate, 3-7 (-10) mm. long, 0.9 to 2.1 times as long as broad, rounded or usually bluntly pointed at apex, inequilateral and truncate or rounded at base, marginally serrulate at least toward the apex, shortly crisply villous, less densely so above or glabrate; petioles about 1 mm. long; stipules often united on lower side of stem and distinct above but variable, when united broadly deltoid, 2- to 6-laciniate, the lobes subulate and fimbriate, when distinct narrowly deltoid and acuminate, 2- or 3-laciniate or entire, the lobes subulate, the whole 0.5-0.8 (-1) mm. long; cyathia solitary at the nodes but mostly on congested short densely leafy lateral branches; involucre narrowly turbinate, 0.7-0.9 mm. long to base of glands, white-strigose; glands shortly oblong to round, 0.1-0.3 mm. long, cupped, often blood-red; appendages ochroleucous to pinkish (not white), 1 to 2 times as long as the gland is wide, marginally entire to erose; *staminate flowers* 3 to 7 per cyathium; *pistillate flower*: styles 3, about 0.2 mm. long, essentially entire, subclavellate, often yellowish-brown with slightly enlarged blood-red tip; capsule ovoid, roundly triangular, 1.4-1.6 (-1.9?) mm. long, truncate basally, with spreading or strigose pubescence more dense on the margins; columella 1.2-1.3 mm. long; seed oblong-quadrangular, 1.1-1.2 (-1.4?) mm. long, apically acute, basally truncate, with shallow irregular pits to subregular indistinct transverse wrinkles, pale-brown with thin white coat, ecarunculate. *Chamaesyce stictospora* (Engelm.) Small. Commonest in disturbed calcareous areas or areas of dark basic igneous rocks in the Trans-Pecos, infrequent in the Plains Country and Edwards Plateau, rare as a waif e. to n.-cen. Tex., July-Sept.; Wyo. and S.D., s. to Coah. and Zac., rare s. to Jal.

61. *Euphorbia prostrata* Ait. Pubescent annual herb; stems several to many, 0.3-1.5 mm. thick, prostrate, 7-20 mm. long, crisply short-villous or glabrate basally; branches numerous, occasionally but not usually pseudodichotomous; leaves opposite; blades oblong to ovate-oblong, 3-11 mm. long, 1.3 to 3 times as long as broad, rounded at apex, inequilateral and rounded at base, marginally serrulate especially toward the apex, sparsely short-villous below, nearly glabrate above; petioles 0.5-1 mm. long; stipules mostly distinct but approximate on lower side of stem, narrowly deltoid, subulate, yellowish to purplish, white-strigose along margins; cyathia solitary at the distal nodes; involucre turbinate, 0.4-0.7 mm. long to base of glands, sparsely villous; glands 4, nearly round, maroon, cupped, 0.05-0.15 mm. long; appendages pinkish-white, shorter than the gland is wide, erose; *staminate flowers* 2 to 5 per cyathium; *pistillate flower*: styles 3, 0.1 mm. long, bifid to the base or nearly so; capsule ovoid-triangular; 1.1-1.3 (-1.4) mm. long, yellowish, strigose or crisply villous along the angles; columella about 1 mm. long; seed oblong, quadrangular, 0.9-1 mm. long, acute at apex, sharply angled, pale pinkish-brown with a white coat, the facets with 5 to 7 low sharp transverse ridges, ecarunculate. *Chamaesyce prostrata* (Ait.) Small. Common in disturbed soils, most of Tex. but infrequent in the far w. part., June-Sept.; widespread in the lowlands of N.A. including the W.I.

For several years, through error, this species went under the name "*E. Chamaesyce* L.," but that name is correctly applied to an Old World species.

62. *Euphorbia laredana* Millsp. Exceedingly similar to *E. prostrata*; distinguished by the seeds averaging slightly larger (1.1-1.3 mm.) with broader more rounded transverse ridges and the herbage grayish-pilose-tomentose. *Chamaesyce laredana* (Millsp.) Small. Local in caliche-sand uplands, Rio Grande Plains (Duval, Frio, Hidalgo, Jim Hogg, McMullen, Starr and Webb cos.), Mar.-Nov.; also Tam.

FAM. 103. CALLITRICHACEAE LINK
WATER-STARWORT FAMILY

Aquatic or terrestrial annual or perennial herbs with delicate stems; leaves opposite, entire, without stipules; flowers unisexual, either both kinds on one plant or on separate plants, the perianth lacking, each flower subtended by a pair of falciform or obliquely oval bracteoles (or these wanting); *staminate flowers* 1 to 3 in the axil of a foliage leaf, consisting of a single anther and slender filament; *pistillate flowers* 1 or rarely more, similarly placed, composed of a single pistil of 2 carpels; styles 2, slender, often much longer than the ovary; carpels splitting on maturity and usually forming a fruit of 4 achenelike mericarps; mericarps flattened, winged, margined or smooth, each bearing 1 seed.

A monotypic family.

1. CALLITRICHE L.¹¹⁹

WATER-STARWORT. WATER-CHICKWEED

Characters of the family. A group of highly polymorphic species due to apomixis in many of the species and to variations and different outward appearances resulting from the same species inhabiting diverse habitats, either amphibious or terrestrial.

About 25 species distributed throughout the world.

1. Fruit as high as wide or a little higher, rarely slightly wider than high; stigmas to 6 mm. long; stamens elongating to 1.5-3 mm. as the fruit matures; anthers to 1.5 mm. wide; flowers with 2 whitish inflated bracteoles at base; leaves of various types on different or the same plant; plant amphibious, growing entirely submersed or with a terminal rosette of floating leaves, or as a mat on mud (2)
1. Fruit broader than high; stigmas to 1 mm. long; stamens to 1.2 mm. long and not elongating as the fruit develops; anthers 0.1-0.2 mm. wide; flowers without bracteoles; leaves essentially uniform; plants mostly terrestrial or on mud (3)
- 2(1). Height of fruit exceeding the width by 0.2 mm.; lower end of mericarps curved outward so that the fruit is thickest at base1. *C. verna*.
2. Height of fruit equaling width or not varying by more than 0.1 mm.; lower end of mericarps straight so that fruit is thickest a little below the middle; commissural grooves very narrow2. *C. heterophylla*.
- 3(1). Fruit 0.3-0.8 mm. wide, more or less gibbous at base3. *C. peploides*.
3. Fruit 0.5-1.2 mm. wide, not gibbous at base (4)
- 4(3). Fruit pedicelled; wing and thin margin of carpel turned outward at right angles to the surface of the fruit or revolute and appearing like a thickened margin4. *C. Nuttallii*.
4. Fruit almost sessile; margin of carpel appearing as if not winged but under high magnification showing a minute wing; styles usually deflexed5. *C. terrestris*.

1. *Callitriche verna* L. (*emend.* Kütz.) Fruits sessile, suborbicular, 0.6-1.4 mm. wide, the height always exceeding the width, the width greatest above the middle, the thickness at base greater than at summit; face of mericarps sharply reticulate, the reticulations appearing more or less clearly in vertical rows; margins of carpels widely spreading with a definite scarious wing that is always widest at summit and runs a greater or lesser distance down the sides; pale-green submersed aquatic or sometimes terrestrial on the margin of ponds or streams; stems to about 5 dm. long; leaves very variable, the lower submersed ones often linear, 0.3-1 mm. wide, 1-nerved, shallowly bidentate at apex, the upper ones often dilated and the terminal leaves petioled and narrowly obovate to spatulate and commonly in a floating rosette, various intermediate leaves are present on many plants. *C. palustris* L. In quiet shallow water or stranded on mud in e. and cen. Tex.,

¹¹⁹ Adapted from N. C. Fassett in *Rhodora* 53:137-155, 161-194, 209-222. 1951.

Mar.-June; from Greenl. to Alas., s. to Tex., N.M., Ariz. and Calif.; also Mex., Eur. and Asia.

Young fruits of *C. verna*, when pressed, sometimes widen as they flatten to simulate in outline those of *C. heterophylla*.

2. *Callitriche heterophylla* Pursh (*emend.* Darby). Fruit 0.6-1.2 mm. wide, the height equaling the width or not more than 0.1 mm. greater or 0.1 mm. less than the width; carpels more broadly rounded at summit than at base so that the outline of the fruit is slightly heart-shaped, convex on the face and thickest just above the base; margins of fruits wingless or rarely with a very narrow wing at the summit; styles 1-6 mm. long, erect or spreading, persistent or caducous; plants rather dark-green; leaves of many types, often linear and one-nerved at the lower nodes with a rosette of floating obovate leaves or (on plants stranded on mud) all linear or all obovate or oblong; linear one-nerved leaves shallowly bidentate at tip with an enlarged but scarcely excurrent nerve-ending. In quiet waters and on mud throughout Tex., Feb.-July; from e. Can., throughout the U.S., s. through Mex. to Guat.

3. *Callitriche peploides* Nutt. Fruit black when ripe, 0.5-0.8 mm. wide, not quite so high; mericarps narrowed and elongated at base, pushing against each other so that each is bent at an angle with the face and the fruit appears greatly thickened at base; stigmas about 0.2 mm. long, often persistent and loosely reflexed; filaments about 0.2 mm. long; anther about 0.1 mm. wide; stems rooting below and apparently creeping, the erect branches 1-5 cm. high; leaves only slightly crowded at the tips of the branches, 2-5 mm. long, cuneate to spatulate-obovate, 1- to 3-nerved but often so faintly as to appear nerveless. On mud and in wet sands throughout the e. half of Tex., Feb.-May; from S.C. to Fla., s.e. Ark. and w. to Tex.; also e. Mex. to C.R.

4. *Callitriche Nuttallii* Torr. Fruit with pedicels of various lengths, buried in the mud at maturity, 1 mm. wide, 0.6-0.8 mm. high, 0.3-0.5 mm. thick; mericarps with flat faces, the margins with a thin wing that is curled toward the face to give the appearance of thickened margins; stigmas about 0.8 mm. long, sometimes persistent and loosely ascending or somewhat reflexed; filaments 0.2-0.5 mm. long; anthers 0.2-0.3 mm. wide; plant a minute annual; leaves 3-4 mm. long, 0.5-1.5 mm. wide, oblanceolate-obovate, very obscurely 3-veined. In damp soil in fallow fields and flats in e. Tex., Mar.-May; along Gulf Coast from Ala. to Tex., inland to cen. Ala. and Ark.

5. *Callitriche terrestris* Raf. (*emend.* Torr.). Fruit 0.6-0.9 mm. wide, 0.4-0.7 mm. high, with pedicels mostly 0.2 mm. long or rarely reaching 0.6 mm. long; mericarps usually equally rounded at each end but rarely broadly rounded above so that the fruit becomes slightly heart-shaped; faces of mericarps flat; outer edges of mericarps appearing scarcely winged but under high magnification showing a very narrow wing with radii but little anastomosing of radii; stigmas 0.2-0.4 mm. long, usually persistent and deflexed; anthers 0.1-0.2 mm. wide, on filaments 0.1-0.2 mm. long; a minute annual with simple to much-branched slender stems to about 35 mm. long; leaves rather uniform, obovate-oblanceolate to spatulate, 2-3.5 mm. long, 0.6-1 mm. wide, very obscurely 3-nerved; *C. Austinii* Engelm., *C. deflexa* A. Br. var. *Austinii* (Engelm.) Hegelm. On damp soil, moist pathways, wet open spots in lawns and other such places in e. Tex., Mar.-June; from N.E., s. to s.e. Va., w. Ala., La., Tex., Mo. and Ill.

FAM. 104. ANACARDIACEAE LINDL.¹²⁰

SUMAC FAMILY

Trees, shrubs or vines with resin-ducts in the bark and sometimes in the herbage, with a resinous or milky and usually acrid juice; leaves alternate or rarely opposite, simple to 3-foliolate or pinnate, deciduous or persistent, usually essentially exstipulate; flowers numerous, small, in terminal thyrses or axillary panicles, or rarely in clusters of spikes, perfect or unisexual through abortion, mostly regular with 5-parted (less often 3- or 4-parted) whorls; receptacle various, flat, concave or convex, sometimes forming a cushionlike gynophore, developing into a ring- or cup-shaped disk; calyx inferior, rarely

¹²⁰ Adapted partly from Fred A. Barkley in C. L. Lundell, *Flora of Texas* III:89-108. 1943.

lacking; corolla seldom lacking; stamens as many as and alternate with the petals, sometimes twice as many or partially aborting; carpels 1 or 2 to 5 united; styles separate or more usually coalesced; fruit various, dry or drupaceous, with resinous or ceriferous mesocarp and crustaceous or bony endocarp (stone); seed with little or no endosperm.

About 60 genera and nearly 600 species, mostly in the tropics. The African sumac [*Searsia lancea* (L. f.) Barkl.] has been introduced into Texas as an ornamental, and it may eventually become naturalized. It is an innocuous shrub or small tree somewhat similar in appearance and in fruit characteristics to our native virulently poisonous swamp sumac (*R. Vernix*), but it is an upland plant that usually has three or rarely five leaflets and resinous, not waxy, mesocarps.

- 1. Flowers without perianth1. *Pistacia*, p. 987.
- 1. Flowers with sepals and petals (2)
 - 2(1). Flowers with twice as many stamens as petals; seed suspended; endocarp of fruit bony2. *Schinus*, p. 987.
 - 2. Flowers with as many stamens as petals (3)
 - 3(2). Style or stigma lateral on the fruit; seed basal; leaves simple; pedicels of sterile flowers at length becoming plumose3. *Cotinus*, p. 988.
 - 3. Style or stigma more or less at the apex of the ovary; leaves trifoliolate to imparipinnate4. *Rhus*, p. 988.

1. PISTACIA L.

A genus of about 10 species found in the Mediterranean region, with several in America. The Old World species, *P. vera* L., produces the edible nut of commerce.

1. *Pistacia texana* Swingle. AMERICAN PISTACHIO, MEXICAN PISTACHIO, LENTISCO. Shrub or small tree to about 4 m. high; branches slender, at first puberulent and grayish-tan, becoming glabrate and brownish; leaves alternate, imparipinnately compound with as many as 21 leaflets; leaflets thinly subcoriaceous, usually strongly falcate, obovate or rarely broadly lanceolate or ovate, to 2 cm. long and 1 cm. wide, rounded or obtuse and mucronate at apex, broadly cuneate at base, sparsely puberulent to glabrous, somewhat darker above, the margins entire or slightly irregular and subrevolute; rachis subalate; pistillate and staminate flowers on separate plants; flowers small, sessile or subsessile in lateral spikes; bracts deltoid-ovate, subacute, about 1.5 mm. long, sparsely puberulent; sepals and petals none; stamens 5; fruit red, a nutlike drupe, about 3.5 mm. wide and 5 mm. long, covered with a bloom, becoming almost black on drying. *P. mexicana* of auth. On limestone cliffs and along ravines, Bexar to Val Verde cos. on the Edwards Plateau, throughout the year; also n. Mex.

2. SCHINUS L. PEPPER-TREE

Dioecious evergreen or semievergreen trees or large shrubs; branches with resin-ducts in the cortex and pith; leaves alternate, simple or odd-pinnate, resinous; flowers in bracteate panicles, small, whitish; sepals 5; petals 5, imbricated; stamens 10; ovary sessile, producing a globose drupe.

About 30 species, mostly in South America.

- 1. Inflorescence a pseudoraceme, very short, congested; leaves simple, glabrous at maturity, thinnish, entire, spatulate, obtuse or rarely subacute at apex, narrowly cuneate at base, 2-5 cm. long; petioles 2-4 mm. long; stems spinescent1. *S. longifolius*.
- 1. Inflorescence a panicle, often exceeding the leaves in length; leaves pinnately compound, usually with 17 or more lanceolate leaflets; stems not spinescent2. *S. molle*.
- 1. *Schinus longifolius* (Lindl.) Speg. & Girola. Shrub or small tree; branches few, spinescent, glabrous; branchlets moderately slender; leaves with slender glabrous petioles 2-4 mm. long, at first with a few long hairs, soon glabrate, 2-5 cm. long, 3-12 mm. broad,

thin, narrowly cuneate at base, mostly obtuse at the apex, rarely subacute, essentially entire; inflorescence about 1 cm. long, congested, many-flowered, the axis glabrous or rarely with a few scattered hairs; bracts deltoid to ovate, subacute, glabrous or rarely very sparsely pilose on the dorsal surface, sparsely ciliate, at length deciduous; pedicels about 4 mm. long, slender, glabrous or rarely sparsely short-pilose below the abscission plate; sepals deltoid-ovate, rounded at apex, glabrous on the outer surface, densely ciliate with simple hairs on the margin; petals narrowly ovate, 2 mm. long, 1 mm. broad, with a few hairs on the veins on the dorsal surface or glabrous; anthers ovate; fruit about 6 mm. in diameter, lavender. Introd. into s. Tex. as an ornamental, and apparently naturalized in several localities; nat. of e.-cen. S.A.

2. *Schinus molle* L. PERUVIAN PEPPER-TREE, PIRUL. Tree to 15 m. high, with numerous slender drooping branches and branchlets to form a spreading crown; leaves with petioles 2-3 cm. long, imparipinnately compound, at length thick-membranaceous, to 3 dm. long, glabrous or very sparsely and minutely puberulent; leaflets 15 to 40, sessile, lanceolate to linear-lanceolate, to 6 cm. long, cuneate to obtuse at base, acuminate or rarely acute at apex, the tip usually curved, entire or nearly so, slightly darker above; inflorescences consisting of a terminal thyrus and much-branched panicles axillary in the uppermost leaves, each 8-15 cm. long and minutely puberulent; bracts deltoid, ciliate, very sparsely and minutely puberulent on the dorsal surface, caducous; flowers small, yellowish-white; pedicels about 2 mm. long, slender, puberulent below the abscission plate, glabrous above; sepals semiorbicular, glabrous on the outer surface, sparsely ciliate with simple trichomes; petals narrowly ovate, truncate, glabrous, about 2 mm. long; anthers oblong; fruit lavender-pink, 6-8 mm. in diameter, vernicose. Occasionally volunteering in the Brownsville district where it was introd. as an ornamental; nat. of S.A.

3. COTINUS MILL.

Two or three species in Europe and Asia, 1 in southwest China and 1 in North America.

1. *Cotinus obovatus* Raf. AMERICAN SMOKE-TREE, CHITTAM-WOOD. Small deciduous tree to about 10 m. high, with yellow wood, scaly bark and strong-smelling juice; twigs at first glaucous, later becoming brown; leaves alternate, with petioles 1.5-6 cm. long, scattered, thin, obovate to elliptic-obovate, to 17 cm. long and 9 cm. broad, rounded to obtuse or somewhat acutish at the apex, rarely emarginate, usually cuneate at the base, silky-pubescent beneath when young, at maturity dark-green and smooth above, paler and sparsely pubescent beneath, turning brilliant orange and scarlet in the autumn; staminate and pistillate flowers on separate plants or occasional flowers appearing perfect; flowers numerous, yellowish-white, 5-merous, in short lax terminal panicles about 1 dm. long, mostly abortive, the fruiting panicles about 3 dm. long; sterile pedicels with rather inconspicuous pale-purplish or brownish hairs; bracts of the inflorescence lanceolate, more or less persistent; sepals lanceolate, acute, 1 mm. long, 0.3 mm. broad, persistent, glabrous; petals oblanceolate, rounded, 2 mm. long, 1 mm. broad, glabrous; stamens inserted under the annular disk; fruit produced sparingly, 4 mm. long, reniform. *C. cotinoides* (Nutt.) Britt., *C. americanus* Nutt., *Rhus cotinoides* Nutt. In rocky woods and on hillsides and limestone outcrops, from Kendall and Kerr to Uvalde cos. on the Edwards Plateau, Apr.-May; Ala., Tenn. and Mo., s.w. to Okla. and Tex.

The Old World wig-tree, *C. Coggygria* Scop., is sometimes cultivated in Texas and may eventually become an escapee. It has glabrous leaves 3-8 cm. long, perfect flowers and fruits 3-4 mm. long.

4. RHUS L. SUMAC

Shrubs or small trees, rarely vines; leaves alternate, simple or compound (in ours); flowers polygamous, in axillary or terminal panicles; calyx lobes 4 to 6, usually 5, persistent; petals imbricated in the bud, spreading in anthesis; disk annular; stamens 5; ovary 1-celled, 1-ovuled; styles 3, terminal; drupe small, subglobose or compressed, pubescent or glabrous, the exocarp persistent or deciduous; seed solitary, inverted on a stalk that rises from the base of the ovary.

About 250 species of temperate and tropical regions, most abundant in South Africa. The vernacular name is commonly pronounced "shumac."

1. Drupes white or dun-colored, glabrous or sparingly pubescent, the pubescence not glandular; poisonous small trees, shrubs or vines (2)
1. Drupes red, noticeably pubescent; plants innocuous (5)
- 2(1). Leaflets 5 to 17; large shrubs or trees, in wet habitats 1. *R. Vernix*.
2. Leaflets typically 3; small shrubs or vines of usually dryish habitats (3)
- 3(2). Terminal leaflet oblong-elliptic, with broad blunt apex; leaflets entire or with shallow rounded lobes or broad blunt teeth; low creeping shrub 2. *R. Toxicodendron* var. *Toxicodendron*.
3. Terminal leaflet ovate or rhombic, with narrowed apex; usually with some leaflets deeply lobed or sharply toothed (4)
- 4(3). Petioles and lower surface of leaflets pubescent; low or high-climbing vine, sometimes creeping and with erect branches to 18 dm. tall 2. *R. Toxicodendron* var. *vulgaris*.
4. Petioles and leaflets glabrous; low shrub usually less than 10 dm. tall, forming beds from creeping rootstocks 2. *R. Toxicodendron* var. *eximia*.
- 5(1). Flowers in dense terminal thyrses, appearing after the leaves; bracts linear-lanceolate, deciduous, one subtending each flower; bracteoles absent; branches thick (6)
5. Flowers in terminal and lateral compound spikes, appearing with or before the leaves; bracts deltoid to ovate, persistent, one bract and two bracteoles subtending each flower (8)
- 6(5). Leaf rachis not winged; leaflets mostly sharply toothed 3. *R. glabra*.
6. Leaf rachis winged; leaflets mostly entire (7)
- 7(6). Rachis and its wings on at least some of the leaves over 4 mm. broad; leaflets 7 to 17, ovate-lanceolate, scarcely falcate, 2 to 4 times as long as wide; in eastern half of Texas 4. *R. copallina*.
7. Rachis and its wings usually less than 3.5 mm. broad; leaflets 13 to 19, linear-lanceolate, strongly falcate, 4 to 9 times as long as wide; in north-central Texas, Edwards Plateau and Trans-Pecos regions 5. *R. lanceolata*.
- 8(5). Flowers usually appearing with the leaves; evergreen shrubs and trees; leaves coriaceous, imparipinnately compound; axillary inflorescences surpassed by the subtending leaves (9)
8. Flowers usually appearing before the leaves; mostly deciduous shrubs; leaves usually herbaceous (10)
- 9(8). Leaflets sparsely pubescent beneath, soft to the touch; inflorescences few, usually terminating the branches 6. *R. virens*.
9. Leaflets glabrous, not soft to the touch; inflorescences usually numerous, both axillary and terminal 7. *R. choriophylla*.
- 10(8). Spinescent shrubs with very small 3- to 9-foliolate leaves; rachis winged; bracts and bracteoles approximately the same size 8. *R. microphylla*.
10. Gracefully diffuse or subscaudent shrubs; leaves 3-foliolate; rachis not winged; bracteoles much smaller than the bracts (11)
- 11(10). Terminal leaflet 25-60 mm. long, more or less narrowed at apex 9. *R. aromatica* var. *serotina*.
11. Terminal leaflet 15-33 mm. long, abruptly narrowed to truncate at apex (12)
- 12(11). Mature leaves glabrous 9. *R. aromatica* var. *flabelliformis*.
12. Mature leaves densely pubescent 9. *R. aromatica* var. *pilosissima*.

1. *Rhus Vernix* L. POISON SUMAC, POISON ELDER, POISON DOGWOOD. Shrub or small tree to 7 m. high; branchlets glabrous, glaucous at first, gray at maturity; leaves odd-pinnate, with glabrous petioles; leaflets 5 to 13, short-stalked, elliptic to elliptic-oblong, 4-10 cm. long, acuminate at apex, cuneate at base, entire, slightly pubescent at first, becoming quite glabrous, with 8 to 12 pairs of veins; flowers greenish, in slender axillary panicles to 2 dm. long; fruit subglobose, compressed, 5-6 mm. across, whitish or light yellowish-gray. In swamps, on seepage slopes and in wet thickets in e. Tex., Apr.-June; from Fla. to Tex., n. to N.E. and s.e. Minn.

The plant, at all seasons, is virulently poisonous to the touch. The leaves turn to orange or scarlet in the fall and are most attractive but dangerous!

2. *Rhus Toxicodendron* L. POISON IVY, POISON OAK, HEDRA. Small shrub or vine with slender glabrate to densely pubescent or puberulent stems and branches, sometimes with aerial roots and/or subterranean stolons; leaflets 3, very rarely with some 5, variable, at first more or less pubescent, later glabrate (especially above) or somewhat pubescent beneath, ovate to elliptic or rhombic to obovate, entire or irregularly serrate or dentate to regularly lobate-dentate with 3 to 7 rounded blunt or rarely subacute lobes, rounded to acute or acuminate at apex, rounded to cuneate at the base; terminal leaflet 3-20 cm. long, 1.5-13 cm. wide, with a petiolule 1-4.5 cm. long; lateral leaflets somewhat smaller than terminal one, inequilateral, often subentire on the upper margin and 3- to 7-lobed on the lower margin, with petiolules 1-5 mm. long; inflorescence composed of lateral panicles; fruit mostly whitish or cream-colored, subglobose, 5-7 mm. in diameter, glabrous or somewhat pubescent; seeds about 4 mm. broad, spring-summer; N.S. to B.C., s. to Fla., Ariz. and Oax.

The plants are commonly showy in autumn with the brilliant scarlet or orange tint of their leaves that are very poisonous to the touch. The fumes from burning plants can also be very poisonous. The following varieties, whose difference are given in the key, are in our region.

Var. *eximia* (Greene) McNair [*Rhus verrucosa* Scheele, *R. radicans* var. *verrucosa* (Scheele) Fern. and var. *Rydbergii* (Small) Rehd., *Toxicodendron eximium* Greene, *T. radicans* var. *eximium* (Greene) Barkl. and var. *verrucosum* (Scheele) Barkl.]. In uplands and on limestone outcrops, rather frequent in cen. and w. Tex.

Var. *Toxicodendron* [*Rhus Toxicodendron* var. *quercifolia* Michx., *Toxicodendron quercifolium* (Michx.) Greene]. In sandy woods and open areas mostly in e. Tex.

Var. *vulgaris* Michx. [*Rhus Toxicodendron* var. *microcarpa* Michx. and var. *radicans* (L.) Torr., *R. radicans* L. and var. *vulgaris* (Michx.) DC., *Toxicodendron radicans* (L.) O. Ktze.]. Stream bottoms or hillside woods or thickets, fencerows and disturbed soils, rather frequent throughout most of Tex.

3. *Rhus glabra* L. SMOOTH SUMAC, SCARLET SUMAC. Shrub or small tree to 3 m. high; branchlets glabrous and somewhat glaucous; leaflets 11 to 31, lanceolate to oblong-lanceolate, to 12 cm. long, acuminate at apex, sharply serrate, glaucous beneath; flowers greenish, in a large dense terminal panicle to 25 cm. long, puberulous; fruit scarlet, viscid-pubescent, compressed, about 4 mm. in diameter, in dense panicles. On dry sandy hillsides and banks, in e. Tex. w. to Brazos, Eastland and Armstrong cos., May-July; from N.E. and Que. s. to Fla., Tex., Ariz. and n. Mex.

This species has bright autumn foliage and scarlet fruiting panicles. The somewhat similar staghorn or velvet sumac (*R. typhina* L.), of eastern United States, is occasionally cultivated in Texas and may eventually be found as an escapee. It may be distinguished from *R. glabra* by its densely pilose branchlets and inflorescences.

4. *Rhus copallina* L. WING-RIB SUMAC, DWARF SUMAC, SHINING SUMAC. Large shrub or small tree to 10 m. high, with rather slender branches; older branches with numerous conspicuous lenticels, glabrate, the new branches villous-tomentose; buds tan, lanuginous; leaves compound, to 35 cm. long, with petioles 3-6 cm. long; leaflets 7 to 11, sessile or with the terminal one petiolulate, elliptic-lanceolate to ovate-lanceolate, thin, subrevolute, green, glabrous or sparsely pilose and shining above, somewhat lighter and glandular-hairy on the dull lower surface, entire or serrate-margined, to 85 mm. long and 4 cm. wide, obtuse to acute or less often acuminate at the apex, usually somewhat unequally cuneate at base; rachis segments 15-25 mm. long, winged, the uppermost broadly so; inflorescence a large terminal thyrses about 12 cm. long and 1 dm. broad; flowers greenish-

white; fruit about 4 mm. in diameter, somewhat flattened, with red glandular hairs; seeds 2.5 mm. in diameter, smooth or somewhat roughened, usually larger at one end. *R. copallina* var. *latifolia* Engl. On rocky hills and in woods and bottomlands in the e. half of Tex.; from N.E. to Ill., s. to Ga., Ala., La. and Tex.

Occasionally planted for its lustrous leaves that change to reddish-purple in the fall and for its crimson fruit clusters.

5. *Rhus lanceolata* (Gray) Britt. Small tree or large shrub to 10 m. high, with slender branches; older branches with numerous lenticels on the brown bark, the younger ones villous but soon glabrate; buds whitish, tomentose; leaves compound, with petioles 25-35 mm. long; leaflets 13 to 19, sessile or the terminal one petiolulate, linear-lanceolate, falcate with the abaxial side wider than the adaxial side, thin, subrevolute, entire or subserrate-margined, green and shining above, pilose and somewhat glandular-hairy on the lighter and dull lower surface, to 55 mm. long and 12 mm. wide near the apex, long-acuminate to acuminate, asymmetric at the cuneate base; rachis segments 13-17 mm. long, winged (the lower ones often obscurely so); inflorescence a large terminal thyrse, about 1 dm. long and 7 cm. broad; flowers whitish; fruit 3.5 mm. long, 4 mm. broad, somewhat flattened, red; seeds 3 mm. long, 2 mm. broad, smooth, slightly larger at one end. *R. copallina* var. *lanceolata* Gray. On limestone and in calcareous soils from n.-cen. Tex. and the e. edge of the Edwards Plateau, w. to the Trans-Pecos; also N.M.

6. *Rhus virens* Gray. EVERGREEN SUMAC, TOBACCO SUMAC, LENTISCO. Shrub or small tree to 3 m. high or more; branches brown, at first puberulent, later glabrate; leaves compound, evergreen, with petioles about 15 mm. long; leaflets mostly 5 to 9, petiolulate, rhombic-ovate to rarely ovate or ovate-lanceolate, cuneate at the base, coriaceous, subrevolute and entire-margined, pubescent but shining and dark above, pale and sparsely soft-pilose (with some glandular hairs) beneath, to 4 cm. long and 2 cm. wide; flowers creamy-white or white, in terminal panicles about 4 cm. long; fruit about 6 mm. long, pubescent with simple and glandular hairs. *Schmaltzia virens* (Lindh.) Small. In gullies and on rocky bluffs, slopes and banks, on dry hillsides and mt. sides in the Edwards Plateau and Trans-Pecos; w. to n. Mex.

7. *Rhus choriophylla* Woot. & Standl. EVERGREEN SUMAC, TOUGH-LEAVED SUMAC. Low shrub or small tree to about 3 m. high, with few branches; branches maroon-brown, with a gray puberulence; leaves evergreen; leaflets 3 or 5, petiolulate, ovate, acute to short-acuminate at apex, obtusely rounded to subcuneate at base, coriaceous, glabrate, subrevolute and entire-margined, pale-green, rather dull above and beneath, to 5 cm. long and 25 mm. wide; flowers whitish or creamy-white, in terminal and axillary panicles about 5 cm. long; fruit red, about 7 mm. long, pubescent with simple and glandular hairs. *Schmaltzia choriophylla* (Woot. & Standl.) Barkl. On hills and mts. in the extreme w. Edwards Plateau and Trans-Pecos; w. to Ariz. and n. Mex.

This plant is very close to *R. virens*, from which it differs in having usually larger, glabrate leaflets and more frequently occurring axillary inflorescences.

8. *Rhus microphylla* Engelm. DESERT SUMAC, SCRUB SUMAC, SMALL-LEAVED SUMAC, CORREOSA. A much-branched shrub or rarely small tree to about 5 m. high, usually much smaller; branches tending to be spinescent, brown, at first puberulent; leaves deciduous, the rachis winged; leaflets 5 to 9, sessile, not leathery or shiny, pilose, less than 2 cm. long and 6 mm. wide, rounded to acutish at apex; flowers appearing before the leaves, not very numerous, often in axillary as well as terminal inflorescences about 5 cm. long; fruits red when mature, glandular-pubescent, about 5 mm. in diameter. *Schmaltzia microphylla* (Engelm.) Small. In scrub, dry uplands, thickets and open alkali flats, on desert plains, dry rocky river-banks, mesas and foothills in the w. three-fourths of Tex.; w. to Ariz. and n. Mex.

9. *Rhus aromatica* Ait. POLECAT BUSH, FRAGRANT SUMAC, SWEET-SCENTED SUMAC, LEMON SUMAC. Straggly to upright shrub with ascending branches, to about 2 m. high, pungently fragrant when bruised; branches light-brown at first, usually slender, puberulent or sometimes glabrate; leaves deciduous, with petioles to about 25 mm. long; leaflets 3, thin to somewhat thickened, sessile or subsessile, at first puberulent, later glabrate; terminal leaflet broadly ovate to rhombic-ovate, 2-9 cm. long, 1.5-8 cm. broad, crenate-dentate to serrate near the apex, entire and abruptly cuneate at the base; lateral leaflets oval, 35-45 mm. long, 17-35 mm. wide, crenate-dentate to serrate near the apex, entire

and obtuse at the base; inflorescence a terminal compound spike, about 6 cm. long and 3 cm. broad; flowers pale-yellow; fruit red, subglobose-compressed, 5-6 mm. in diameter, pubescent with simple and glandular hairs. *Schmaltzia crenata* (Mill.) Greene. Apr.-May; from Fla. to Tex., n. to N.E. and Que., w. to Neb., Kan. and Okla.

A conspicuous plant in early spring with its yellow flowers and in fall with the leaves turning orange and scarlet. The following varieties, whose differences are noted in the key, occur in our region.

Var. *flabelliformis* Shinnery (*Rhus trilobata* of auth.). In scrub on limestone outcrops and rocky slopes, prairies, mesquite plains and in sandy woodlands in cen. and w. Tex.

Var. *pilosissima* (Engl.) Shinnery [*Rhus trilobata* var. *pilosissima* Engl., *Schmaltzia trilobata* var. *pilosissima* (Engl.) Barkl.]. In loose sands, sandy soil and on hills in the Panhandle and Trans-Pecos.

Var. *serotina* (Greene) Rehd. [*Schmaltzia serotina* Greene, *S. trilobata* var. *serotina* (Greene) Barkl.]. In sandy woodlands and in ravines in the e. half of Tex.

FAM. 105. CYRILLACEAE ENDL.*

CYRILLA FAMILY

Shrubs or trees; leaves alternate, simple, without stipules, usually borne at the ends of the branchlets, chartaceous to coriaceous, entire, persistent, petiolate; flowers small, regular, perfect, borne in narrow lateral or terminal racemes or panicles; calyx usually 5- (rarely 4- to 8-) parted; sepals equal or unequal, imbricate, persistent; petals hypogynous, the same number as the sepals, sessile or short-clawed, free (in ours), slightly convolute, deciduous; stamens hypogynous, 5 or 10, when 5 alternate with the petals, when 10 those opposite petals shorter; filaments subulate or flattened, distinct, sometimes appendaged; anthers basifixed or dorsifixed, 2-celled, longitudinally dehiscent; disk annular, subcupular or cylindric, confluent with the base of the ovary; ovary superior, 2- to 5-celled, terete or angled; ovules anatropous, 1 or 2 pendulous from the apex of the cell or 3 (rarely 2 or 4) attached to a short placenta pendulous from the apex of the cell; style elongate or wanting; stigma entire or 2- to 5-lobed; fruit small, crustaceous or spongy, indehiscent, sometimes winged; seed usually solitary in each cavity, elongated, with fleshy endosperm; embryo central, elongated; radicle superior.

A small American family of 3 genera and about 13 species.

1. Flowers in lateral racemes; petals lanceolate, acute; stamens 5; ovary 2-celled; fruit ovoid, not winged1. *Cyrilla*, p. 992.
1. Flowers in terminal racemes; petals obovate, rounded; stamens 10; ovary 3- or 4-celled; fruit usually 3-winged2. *Cliftonia*, p. 993.

1. CYRILLA L.

A variable but apparently monotypic American genus.

1. *Cyrilla racemiflora* L. LEATHERWOOD, BLACK TITI. Usually small trees, to 10 m. tall, with a trunk to 3 dm. in diameter; leaves alternate, petiolate, oblanceolate, chartaceous to coriaceous, usually widest above the middle, entire, usually turning a rusty-red or -yellow in the fall; racemes slender, lateral, clustered, arising at the base of twigs of current year, 6-18 cm. long, spreading; flowers numerous, fragrant; pedicels 1.5-3 mm. long, basally jointed, with 1 conspicuous persistent bract at base and 2 persistent bractlets below the calyx; calyx small; sepals 5, equal, acute, coriaceous; petals 5, white, lanceolate to oblong-lanceolate, 2.5-3.2 mm. long; stamens 5, equal, inserted at the base of the corolla; filaments subulate; disk cylindric; ovary oblong, 2-celled; style short, stigma 2-lobed; ovules 3 (rarely 2 or 4) attached to a short placenta pendulous from the apex of the cell; fruit small, indehiscent, ovoid, subterete, 2-3 mm. long, 2-celled, pericarp spongy, cells 1-seeded. In bottomlands, swamps and along streams in s.e. Tex., n. to Trinity Co., May-July; from s. Va., s. to Fla., w. along the coast to Tex.

We have two noticeably distinct flowering forms; plants with racemes mostly less than 10 cm. long and suborbicular-ovoid apically blunted fruits and plants with racemes more than 10 cm. long and narrowly ovoid pointed fruits.

* Cf. C. L. Lundell, *Flora of Texas* III: 109-111. 1943 for a more detailed treatment.

2. CLIFTONIA GAERTN. F.

A monotypic genus of southern United States.

1. *Cliftonia monophylla* (Lam.) Sarg. BUCKWHEAT-TREE. Usually small trees to 15 m. tall, with a trunk to 5 dm. in diameter; leaves alternate, subsessile, coriaceous, elliptic-oblong, obtuse, to about 4 cm. long and 2 cm. wide, usually widest above the middle, entire; flowers very fragrant, in terminal stoutish racemes 2-6 cm. long; pedicels basally jointed, with 1 deciduous bract at base and 2 deciduous bractlets below the middle, 1.5-2.5 mm. long (to 6 mm. in fruit); calyx small; sepals 5 to 8, united at base, equal or unequal; petals 5 to 8, oblong-obovate, narrowed into a short claw, hooded at apex, obtuse or rounded, 3.5-4.3 mm. long; stamens 10, inserted at the base of the corolla, unequal, the 5 opposite the petals shorter; filaments flattened below the middle, subulate above; disk subcupular; ovary 3- to rarely 4-angled, 3- to rarely 4-celled; stigma subsessile, 3- to rarely 4-lobed; ovules solitary in each cell, pendulous from the apex; fruit small, indehiscent, 3- to rarely 4-winged, 3- to rarely 4-celled, 6-7 mm. long, cells 1-seeded; seeds with a soft testa. In pineland swamps on the Coastal Plain from Ga. to n. Fla., w. to La., Apr.-May.

Although at present unknown from Texas it is included here on the basis of its probable occurrence in low savannah-pinelands of the southeastern part of the state.

FAM. 106. AQUIFOLIACEAE BARTL.¹²¹

HOLLY FAMILY

Shrubs or trees, usually evergreen, mostly polygamo-dioecious; leaves alternate, simple, usually stipulate, petiolate, margin entire to toothed or sometimes spiny; inflorescence normally cymose, pedunculate or sessile, axillary, solitary or fasciculate, 1- to many-flowered; flowers regular, small, usually 4- to 6-parted, sometimes more; calyx small, free from the ovary and drupe, persistent, the lobes imbricate; corolla white or greenish, deciduous; petals imbricate, rarely valvate, alternate with the sepals, free or united at the base; stamens usually 4 to 6, inserted at the base of the corolla, alternate with the petals, all fertile; filaments subulate, erect, shorter than the petals; anthers introrse, 2-celled, longitudinally dehiscent; staminodia in pistillate flowers similar to stamens, smaller in size, sterile; ovary free, superior, angled or lobed, sessile, usually 2- to 6- (rarely many-) celled; stigma capitate or discoid, usually sessile, with as many lobes as cells in the ovary; ovules 1 (rarely 2) in each cell, suspended, anatropous; ovary in staminate flowers abortive; fruit drupaceous, globose to ellipsoid or rarely lobed, usually containing 4 to 8 (rarely to 18) horny or crustaceous stones; stones smooth, ribbed or striate, usually 1-seeded; seed suspended, the testa membranaceous, the fleshy endosperm copious.

A family of three genera containing about 500 species.

1. ILEX L. HOLLY

Shrubs or trees; leaves alternate, petiolate, persistent or deciduous, entire to dentate or spinescent; stipules minute, deciduous; staminate and pistillate flowers on separate plants or occasional flowers appearing perfect, small, axillary, cymose, fasciculate or solitary, usually pedicellate; calyx minute, 4- to 9-parted, persistent; corolla rotate; petals 4 to 9, hypogynous, elliptic or oblong, obtuse, free or united at the base, white or greenish, deciduous; stamens inserted on the base of the corolla, as many as and alternate with the petals; filaments subulate; anthers attached on the back, oblong, usually rudimentary in the fertile flower; ovary free, sessile, subcylindrical, usually 2- to 8-celled, rudimentary in the sterile flower; style usually wanting; stigmas as many as the cells of the ovary, distinct or confluent; ovules 1 or 2 in each cell, suspended from near the apex, collateral, anatropous; fruit drupaceous, subglobose, crowned by the persistent stigma, usually containing 4 to 8 bony or crustaceous stones; stones 1-seeded, smooth, ribbed or striate.

¹²¹ Adapted partly from C. L. Lundell, *Flora of Texas III*: 112-122. 1943.

A genus of about 400 species, widely distributed over the temperate and tropical regions of the world, most abundant in China. Many species are grown as ornamentals.

1. Fruit red or black, sometimes yellow, with smooth stones; pistillate flowers with usually 6 to 9 petals and calyx lobes (2)
1. Fruit red or purple, sometimes yellow, with ribbed or striate stones; pistillate and polygamous flowers with usually 4 or 5 (rarely 6) petals and calyx lobes (4)
- 2(1). Sepals ciliate; leaves thin, deciduous 1. *I. verticillata*.
2. Sepals not ciliate but sometimes obscurely ciliolate or erose-denticulate; leaves coriaceous, persistent (3)
- 3(2). Young twigs velutinous-puberulent; leaves crenate or crenate-serrate above the middle, the 1 to 3 marginal teeth closely appressed to sinus, the apex not noticeably spine-tipped 2. *I. glabra*.
3. Young twigs glabrous or viscid-puberulent; leaves mostly spinescent-serrate above the middle, the several teeth erect or spreading, the apex spine-tipped 3. *I. coriacea*.
- 4(1). Leaves relatively thin, deciduous; inflorescence sessile, all the flowers solitary or fasciculate; pedicels without bractlets at base (5)
4. Leaves coriaceous, persistent; inflorescence peduncled, the flowers in cymes or solitary; pedicels with bractlets at base (9)
- 5(4). Sepals and petals ciliate 4. *I. montana*.
5. Sepals entire, not ciliate (6)
- 6(5). Pedicels of fertile flowers mostly less than 4 mm. long; leaf blades broadest at the middle or below it, glabrous beneath 5. *I. ambigua*.
6. Pedicels of fertile flowers 4 mm. or more long; leaf blades broadest above the middle, more or less pubescent beneath (7)
- 7(6). Pedicels 4-6 mm. long; leaf blades mostly spatulate to obovate, attenuate at base, commonly emarginate at apex 6. *I. decidua*.
7. Pedicels 6-30 mm. long; leaf blades typically obovate-elliptic, cuneate at base, acute to acuminate at apex (8)
- 8(7). Leaf blades short-hirtellous or puberulent along midvein beneath 7. *I. longipes* var. *longipes*.
8. Leaf blades hirsute along midvein beneath 7. *I. longipes* var. *hirsuta*.
- 9(4). Leaf blades coarsely toothed (rarely with some entire in *I. opaca*) (10)
9. Leaf blades essentially entire or rarely with several obsolescent teeth above middle (11)
- 10(9). Leaf blades only occasionally with some more than 4 cm. long 8. *I. vomitoria*.
10. Leaf blades usually much more than 4 cm. long 9. *I. opaca*.
- 11(9). Leaf blades typically linear, to 10 mm. wide 10. *I. myrtifolia*.
11. Leaf blades typically oblong-obovate, more than 15 mm. wide 11. *I. Cassine*.

1. *Ilex verticillata* (L.) Gray. BLACK ALDER, WINTER-BERRY. Shrub or small slender tree to 5 m. high; leaves with a petiole 1-1.5 cm. long, round-obovate to elliptic or elliptic-lanceolate, cuneate at base, more or less abruptly acuminate at apex, serrate, appressed-pilose or downy to glabrous beneath, dull above, thin-textured, deciduous, to 8 cm. long and 35 mm. wide; *staminate flowers* clustered, 2 to 10, all short-stalked, 4- to 6-merous; *pistillate flowers* short-stalked, 5- to 8-merous; calyx segments obtuse, ciliate; drupes bright-red varying to yellow, 5-7 mm. in diameter; stones smooth on the back. In or about swamps, pond-margins, river banks and damp thickets in s.e. Tex., Apr.-June; from Nfld. to Minn., s. to Ga. and e. Tex.

2. *Ilex glabra* (L.) Gray. INK-BERRY, GALLBERRY. Shrub to 4 m. high, usually much smaller; twigs slender, angled, finely puberulent; leaves persistent, rather crowded on the short twigs, with finely puberulent petioles usually 2-5 mm. long, coriaceous, lustrous

above, paler on undersurface, oblanceolate to obovate or elliptic, to 5 cm. long and 3 cm. wide, obtuse and mucronulate at apex, acute to subcuneate at base, the margin distantly serrate above the middle with 1 to 3 teeth on each side or rarely entire, punctate, puberulent above along the elevated midvein; inflorescence axillary, peduncled, the staminate with 3 or more flowers, the pistillate 1- to 3-flowered; peduncles slender, puberulent, to 1 cm. long in staminate inflorescence, shorter in pistillate; pedicels puberulent, those of staminate flowers 1-5 mm. long; flowers 5- to 8-parted; calyx glabrous, subcupuliform, 2-3 mm. in diameter, the ovate-triangular lobes often obscurely ciliate; corolla in staminate flowers to 7 mm. wide; petals united at base, broadly elliptic to suborbicular, to 3 mm. long, the margin subentire; stamens and staminodia shorter than the petals; ovary in pistillate flowers suburceolate, about 2 mm. long, 5- to 8-celled, the stigma discoid; drupe globose, black, 5-8 mm. in diameter, 5- to 8-sulcate, crowned by the persistent stigma; stones up to 8 in number, not ribbed, about 4 mm. long. In low sandy soil, usually in pine lands, pine barrens and swamps in n.e. Tex., rare, Feb.-July; from N.S. and e. Mass., s. to Fla. and Tex.

3. *Ilex coriacea* (Pursh) Chapm. BAY-GALL BUSH. Shrub, usually arborescent, evergreen, to 5 m. high and a trunk 5 cm. in diameter; twigs rather slender, subterete or inconspicuously angled, minutely puberulent; leaves with rather stout puberulent petioles 3-10 mm. long, coriaceous, often rigid, dark-green and lustrous above, paler beneath, elliptic to oblong-elliptic or obovate-elliptic to oblanceolate, to 9 cm. long and 3.5 mm. wide, the margin entire or with several small spinescent teeth above the middle, not crenulate, the spinescent apex acute to obtuse or rarely subacuminate, acute or sometimes rounded at base, the midvein puberulent above at first and beneath at base, punctate and sometimes glaucous on the undersurface, the costa conspicuous on both surfaces; flowers solitary or fasciculate, usually in the leaf axils, sometimes appearing racemose on short leafy twigs; pedicels without bractlets at base, those of staminate flowers glabrous and 3-6 (rarely 10) mm. long, those of pistillate flowers puberulent and 5-9 (rarely 15) mm. long; flowers 5- to 9-parted; calyx glabrous, the triangular lobes acute and erose-denticulate, equaling or surpassing the tube; corolla white; petals united at base, elliptic to oblong-elliptic, erose, in staminate flowers to 3.5 mm. long, in pistillate flowers smaller; stamens fully three fourths as long as the petals; staminodia about one half as long as the petals; ovary in pistillate flowers depressed-globose, about 2 mm. long including the short thick style, 4- to 9-celled, the stigma discoid; drupe globose, black, to 8 mm. in diameter, crowned by the persistent stigma; stones as many as 9, laterally compressed, smooth, to 4 mm. long. In swamps, low hammocks and along streams in s.e. Tex., Mar.-Apr.; from Va., s. to Fla. and Tex.

This species is commonly confused with the usually smaller *I. glabra*.

4. *Ilex montana* T.&G. MOUNTAIN-WINTERBERRY. Tall shrub or small tree with slender pubescent to glabrous branchlets, to about 10 m. high; leaves with a petiole about 5 mm. long, elliptic-lanceolate to ovate, membranaceous, broadly cuneate at base, acute to acuminate at apex, sharply serrate, to 1 dm. long and 3 cm. wide, glabrous to velvety-pubescent beneath, often clustered at tips of fruiting spurs; pedicels of pistillate flowers and fruits very short; flowers 4- to 6-merous; calyx ciliate and villous; drupes about 1 cm. in diameter, red or scarlet; stones striately many-ribbed on back. *I. Beadlei* Ashe. On rich wooded slopes in s.e. Tex., Apr.-May; from N.Y., s. to Ala. and e. Tex.

Plants characteristic of our area have been segregated as var. *mollis* (Gray) Britt. because of their pubescence.

5. *Ilex ambigua* (Michx.) Torr. CAROLINA HOLLY, SAND HOLLY. Shrub or small tree, rarely to 6 m. high; twigs slender, glabrous, sulcate at first, subterete with age; leaves deciduous; petioles slender, canaliculate, sparsely hirtellous above, 2.5-7 mm. long; blades membranaceous, sometimes chartaceous with age, slightly paler beneath, elliptic to ovate-elliptic or obovate-elliptic to lanceolate, to 65 mm. long and 33 mm. wide, acute to short-acuminate or sometimes obtuse at apex, cuneate at base, the margin serrulate or crenate-serrulate, the lower third usually entire, sparsely hirtellous above along the midvein, sometimes ciliate; inflorescence axillary, not peduncled, the staminate flowers fasciculate, the pistillate usually solitary; pedicels slender, 1-4 mm. long, glabrous; flowers usually 4- or 5-parted, rarely 3-parted; calyx glabrous, subcupuliform, 1.5-2 mm. in diameter, the broadly ovate lobes apiculate and ciliate; corolla rotate or subrotate;

petals united at base, broadly elliptic, to 2.8 mm. long, ciliolate; stamens and staminodia shorter than the petals; ovary in pistillate flowers ovoid, to 2.5 mm. long, 4- or 5-celled, the stigma capitate; fruiting pedicels very short, usually less than 3 mm. long; drupe subglobose, 5-7 mm. in diameter; stones 4 or 5, striate-sulcate, to 5 mm. long. *I. caroliniana* (Walt.) Trel. In sandy woods, along streams and in hammocks in e. Tex., spring; from N.C., s. to Fla., Ark. and Tex.

6. *Ilex decidua* Walt. POSSUM-HAW, DECIDUOUS HOLLY, WINTER-BERRY. Shrub or small tree to 10 m. high, the trunk to 25 cm. in diameter; twigs terete, pale silvery-gray, glabrous or rarely puberulent, the lateral ones usually spurlike and short, the vigorous shoots slender and elongate; leaves deciduous, usually fascicled on the ends of the short spurlike lateral branches; petioles canaliculate, densely puberulent above with incurved hairs, glabrous beneath, slender, 2-11 mm. long; blades at first membranaceous, firmer with age, pale on undersurface, oblanceolate to oblong-spatulate or obovate to broadly obovate-elliptic, to 8 cm. long and 45 mm. wide, obtuse to rounded or obtusely sub-acuminate at apex, usually emarginate, cuneate or narrowed and acute at base, the margin remotely crenulate-serrulate, the small incurved teeth tipped with glands; flowers solitary or fasciculate, usually aggregated at the ends of the lateral spurlike branches of the previous season, rarely solitary on the shoots of the year, appearing with the leaves; pedicels without bractlets at base, glabrous, those of staminate flowers slender and to 12 mm. long, those of pistillate flowers to 6 mm. long; flowers 4- or 5-parted; calyx lobes triangular, acute, entire or denticulate in staminate flowers, sometimes obscurely ciliolate in pistillate flowers, equaling or surpassing the tube; corolla white; petals united at base, elliptic to oblong-elliptic, 3-3.8 mm. long; stamens in staminate flowers slightly shorter than the petals; staminodia in pistillate flowers about three fourths as long as the petals; ovary in pistillate flowers ovoid, about 1.5 mm. long, usually 4-celled; stigma large, sessile, capitate; drupe globose or depressed-globose, bright-red or orange, to 7.5 mm. in diameter, crowned by the persistent stigma, often persisting on the branches until the leaves appear the following spring; stones usually 4, strongly ribbed, to 5 mm. long. In woods, often bordering streams, swamps or ravines in e. and cen. Tex., Mar.-May; from Va., w. to Ill., s. to Fla., Tex. and Kan.

7. *Ilex longipes* Chapm. GEORGIA HOLLY, CHAPMAN'S HOLLY. Shrub or small tree, rarely to 7 m. high; twigs slender, subterete, glabrous; leaves deciduous; petioles slender, canaliculate, puberulent above with minute incurved hairs, 3-10 mm. long; leaf blades membranaceous or chartaceous with age, dark-green above, paler beneath, elliptic to obovate or oblanceolate-elliptic, to 6 cm. long and 3 cm. wide, short-acuminate to acute or obtusish at apex, minutely mucronulate, subcuneate and acute at base, the margin subcrenulate-serrulate or serrulate, the teeth subappressed-mucronulate, sparsely short-hirtellous above along the midvein, irregularly ciliolate, short-hirtellous or puberulent beneath along the midvein and primary veins; inflorescence axillary, not peduncled, the staminate flowers fasciculate, the pistillate flowers usually solitary; pedicels slender, glabrous, usually 1-2 cm. long, sometimes to 3 cm. long; flowers 4-parted, small; calyx glabrous; staminate calyx subcupuliform, about 2 mm. in diameter, the triangular lobes acute and denticulate; calyx of pistillate flowers slightly larger; corolla rotate; petals united at base, elliptic, to 3.3 mm. long, not ciliolate; stamens subequaling petals, the staminodia a third shorter than petals; ovary in pistillate flowers ovoid, to 2.5 mm. long, 4-celled, the stigma capitate; drupe globose, 5.5-8 mm. in diameter; stones 4, inconspicuously striate-sulcate, to 5.5 mm. long. In woods, often on sandy banks of streams in s.e. Tex., Mar.-May; from N.C. and Tenn., s. to Fla. and Tex.

The var. *longipes* is usually a larger plant than var. *hirsuta* Lundell. Characters used in the key are the main ones for separating these two entities.

8. *Ilex vomitoria* Ait. YAUPON. Shrub or tree, evergreen, to 8 m. high; twigs usually short, rather stout, rigid, obtusely angled, densely puberulent; petioles puberulent, usually 1-3 mm. long, sometimes to 6 mm. long; leaf blades coriaceous, dark-green and lustrous above, paler beneath, elliptic to oblong or oblong-elliptic to ovate-elliptic, sometimes obovate-elliptic, to 55 mm. long and 28 mm. wide, usually much smaller, crenulate to crenate or crenulate-serrulate, the teeth mucronulate, obtuse and usually minutely emarginate and mucronulate at apex, obtuse to rounded or rarely acutish at base, at first puberulent above along the midvein and at base, glabrous otherwise; inflorescences

fasciculate in the leaf axils, the staminate usually 3-flowered, the pistillate 1-flowered; peduncle of staminate inflorescence short, usually puberulent; pedicels 1.3-3.8 mm. long, those of staminate flowers glabrous, those of pistillate flowers puberulent; flowers 4-parted; calyx glabrous, the broadly ovate or rounded lobes about 0.5 mm. long; corolla white; petals united at base, elliptic to oblong-elliptic, 2-3 mm. long, to 2 mm. wide; stamens subequaling the petals; staminodia shorter than the petals; ovary in pistillate flowers conic-ovoid, 1.5-2 mm. long, 4-celled, the stigma capitate; drupe globose, lucid, bright-red, to 6.5 mm. in diameter, crowned by the persistent stigma; stones 4, striate, to 4 mm. long. In low woods, hammocks and sandy pine lands in s.e. and s.-cen. Tex., Apr.-May; from Va., s. to Fla., Ark. and Tex.

This is the most abundant of our hollies. The leaves, which contain a caffeine, were used by the aborigines to decoct a ceremonial drink.

9. *Ilex opaca* Ait. AMERICAN HOLLY. Tree, evergreen, usually small, sometimes to 18 m. high; twigs rather stout, densely puberulent, subterete or striate-sulcate; petioles puberulent, usually 5-12 mm. long, sometimes to 18 mm. long, canaliculate; leaf blades variable, coriaceous, sometimes rigid, dark-green above, paler beneath, elliptic to obovate, to 12 cm. long and 6 cm. wide, acute to subacuminate and spine-tipped at apex, obtuse to rounded or sometimes acutish or subcuneate at base, spinose-dentate or sometimes nearly or quite entire, puberulent above at first along the midvein and at base, often sparsely short-hirtellous beneath along the midvein; inflorescences scattered or fasciculate in the leaf axils, the puberulent staminate cymes 3- to 10-flowered and to 25 mm. long, the pistillate usually 1-flowered; peduncle of staminate inflorescence to 1 cm. long; pedicels puberulent, those of staminate flowers to 7 mm. long and without bractlets, those of pistillate flowers 2-10 mm. long and bearing 2 bractlets near middle; flowers 4-parted; calyx sparsely puberulent or glabrous, ciliate, the ovate-triangular lobes 1-1.5 mm. long and acute or acuminate; corolla white or yellowish; petals united at base, usually elliptic, to 4 mm. long and 3 mm. wide, sometimes sparsely ciliolate; stamens equaling or exceeding the petals; staminodia shorter than the petals; ovary in pistillate flowers conic-ovoid, about 2.5 mm. long, 4-celled, the stigma capitate; drupe globose or ellipsoid, red, rarely yellow, to 12 mm. in diameter; stones 4, ribbed, to 8 mm. long. In moist woods, hammocks, along banks of streams and in swamps in e. and s.-cen. Tex., most abundant near the coast, Apr.-June; from Mass., w. to Wisc., s. to Fla. and Tex.

The small branches of this species, loaded with red "berries," are everywhere gathered for decorative use at Christmas time.

10. *Ilex myrtifolia* Walt. MYRTLE HOLLY. Shrub or small tree, evergreen, rarely more than 5 m. high; twigs rigid, usually slender, finely puberulent; leaves crowded; petioles puberulent above, usually less than 3 mm. long; leaf blades rigidly coriaceous, dark-green above, paler beneath, revolute, linear to narrowly oblong-elliptic or linear-lanceolate, usually 1-2.5 cm. long, sometimes to 4 cm. long, 1 cm. wide, entire or serrate above with a few subappressed spinescent teeth, obtuse or acute and mucronate at apex, obtuse to acutish at base, at first finely puberulent above along the midrib, usually glabrous otherwise, the midrib wide and conspicuous on underside, primary veins often scarcely evident; inflorescence short-peduncled, the staminate 3- to 9-flowered, the pistillate 1-flowered; flowers usually 4-parted; calyx glabrous, 1-1.5 mm. wide, the acute lobes ovate-triangular; corolla in staminate flowers to 5 mm. wide; petals united at base, oblong-elliptic; stamens shorter than corolla lobes; ovary about 2 mm. long, 4-celled, the stigma capitate; drupe red, globose, about 6 mm. in diameter, borne on pedicels about 5 mm. long; stones 4, ribbed. Extremely rare, if still extant, near mouth of Brazos River; to be looked for in and around cypress and pineland swamps near the coast, usually flowering in May; from N.C., s. to Fla. and Tex.

11. *Ilex Cassine* L. DAHOON, DAHOON HOLLY. Small tree, evergreen, to 10 m. high; twigs rather slender, glabrous or pubescent; petioles glabrous or pubescent, canaliculate, stout, to 12 mm. long; leaf blades coriaceous, dark-green and lustrous above, paler beneath, obovate-oblong to oblanceolate or oblong, to 14 cm. long and 45 mm. wide, acute to mucronate or rarely rounded at apex, acute at base, the margin revolute, entire or sometimes serrate above the middle with sharp mucronate teeth, puberulent above, at first densely pubescent beneath but glabrous at maturity except for occasional hairs on the lower surface of the broad midrib; inflorescence peduncled, to 25 mm. long, produced

from the young shoots or occasionally from branches of the previous year, the staminate 3- to 9-flowered, the pistillate usually 3-flowered; peduncles and pedicels pubescent, the peduncles to 15 mm. long but usually much shorter, the pedicels to 6 mm. long; flowers usually 4-parted; calyx glabrous, 1.5-2 mm. in diameter, the ovate-triangular lobes acute to acuminate and ciliate; corolla in staminate flowers to 5 mm. wide; petals united at base, oblong-elliptic, to 2.5 mm. long; stamens subequaling petals; staminodia in pistillate flowers shorter than petals, the small anthers abortive; ovary in pistillate flowers conical, about 2 mm. long, 4-celled, the stigma capitate; drupe globose, red, 5-6 mm. in diameter; stones 4, ribbed, about 4 mm. long. In swamps, hammocks and along streams in s.e. Tex., May-June; from Va., s. to Fla. and Tex.

Texas material is commonly referred to var. *latifolia* Ait.

FAM. 107. CELASTRACEAE R. BR.*

STAFF-TREE FAMILY

Shrubs, woody vines or small trees; leaves simple, opposite or alternate; stipules lacking or minute, fugacious; flowers with jointed pedicels, regular, perfect or unisexual, 4- or 5-merous, the perianth parts imbricated in the bud; stamens 4 to 10, commonly as many as the petals and alternate with them, inserted on a broad flat usually lobed disk that fills the bottom of the calyx and sometimes covers the ovary; ovules anatropous; styles completely united; fruit 1- to 5-celled, free from the calyx; seeds mostly arillate.

About 850 species in more than 50 genera, world-wide in distribution.

1. Leaves opposite1. *Euonymus*, p. 998.
1. Leaves alternate (2)
 - 2(1). Fruit a dehiscent capsule; branches flexible, often vinelike (3)
 2. Fruit a follicle or indehiscent capsule; branches typically rigid, commonly stiffly erect or spreading (4)
 - 3(2). Ovary free from the disk; ovules 2 in each cell; leaves herbaceous; plant scandent; in Trans-Pecos Texas2. *Celastrus*, p. 999.
 3. Ovary confluent with the disk; ovule 1 in each cell; leaves fleshy-coriaceous; plant shrubby; in Rio Grande Valley3. *Maytenus*, p. 999.
 - 4(2). Stamens 10; petals ligulate or oblanceolate; leaves narrowly obtuse to acute at apex4. *Forsellesia*, p. 1000.
 4. Stamens 4 or 5; petals broad; leaves broadly acute to rounded or notched at apex, occasionally mucronate (5)
 - 5(4). Leaves cuneate-obovate to broadly oblanceolate, rounded-cuneate and mostly notched at apex; flowers 4-merous; calyx not tubular; fruit somewhat fleshy, 2-seeded5. *Schaefferia*, p. 1000.
 5. Leaves oval to oblanceolate or suborbicular, acutish to obtuse at apex; flowers 5-merous; calyx tubular-obconic; fruit dry, 1-seeded6. *Mortonia*, p. 1001.

1. EUONYMUS L.

SPINDLE-TREE

Shrubs or small trees with 4-sided green-barked branchlets; leaves opposite, serrulate; flowers small, perfect, 4- or 5-merous, solitary or in loose pedunculate cymes in the leaf axils; sepals united at the base to form a short flat calyx; petals rounded, spreading; stamens short, inserted on the margin of a broad and flat 4- or 5-angled disk that coheres with the calyx to conceal the ovary and more or less adhere to it; style short or none; capsule 3- to 5-lobed and -valved, loculicidal; seeds 1 to 4 in each cell, enclosed in a red aril.

About 175 species, primarily in North America, Eurasia and Australia.

* See Appendix. Cf. C. L. Lundell, *Flora of Texas* II: 339-355. 1969 for a more detailed treatment.

1. Leaves often essentially sessile, with petioles less than 5 mm. long; flowers 5-merous; fruits tuberculate1. *E. americanus*.
1. Leaves with prominent petiole more than 5 mm. long; flowers 4-merous; fruit smooth (2)
- 2(1). Leaves ovate-elliptic to elliptic, acute or abruptly short-acuminate, persistently pubescent beneath2. *E. atropurpureus* var. *atropurpureus*.
2. Leaves lanceolate, attenuate at apex into a long acumen, entirely glabrous2. *E. atropurpureus* var. *Cheatumii*.

1. *Euonymus americanus* L. STRAWBERRY-BUSH, BURSTING-HEART. Low erect or straggling shrub to about 2 m. high; leaves sessile or essentially so, firm, bright-green above, pale beneath, ovate to elliptic or oblong-lanceolate, acute to acuminate, crenulate-serrulate, essentially glabrous, to about 1 dm. long and 35 mm. wide; flowers solitary or in few-flowered cymes, 5-merous, 1-1.2 cm. wide, greenish-purple; petals distinctly clawed; capsules rough-warty, 3- to 5-lobed, depressed, about 15 mm. thick, crimson when ripe, the aril and dissepiments scarlet. In mud along streams, river bottomlands and on forested stream banks in e. Tex., May-June; from Fla. to Tex., n. to N.Y., Pa., W.Va., Ind., Ill., Mo. and Okla.

2. *Euonymus atropurpureus* Jacq. BURNING-BUSH, WAHOO. Erect shrub or small tree to 8 m. high; leaves with petioles 1-2 cm. long, oblong-oval to lanceolate, acute to acuminate or long-attenuate, pubescent beneath or entirely glabrous, 7-13 cm. long, serrulate; peduncles 7- to 15-flowered; flowers dark-red or purple, 4-merous, mostly 6-8 mm. wide; ovules ascending, 2 in each cell; fruits red or purple, depressed-obovoid, about 15 mm. broad, deeply 4-lobed, smooth; seeds brown, with a scarlet aril. Rich moist woods, thickets and ravines, mainly in n.-cen. Tex., Apr.-July; from Ont. to Mont., s. to N.C., Tenn., Ala., Ark., Okla. and Tex.

We have two variants as noted in the key—var. *atropurpureus* and var. *Cheatumii* Lundell.

2. CELASTRUS L.

About 30 species, mostly in eastern Asia.

1. *Celastrus scandens* L. CLIMBING BITTERSWEET, AMERICAN BITTERSWEET. Twining high-climbing shrub to about 15 m. high, the primary stem to 25 mm. thick; leaves alternate, ovate-oblong to elliptic, acuminate, serrulate, 5-10 cm. long; flowers small, greenish, in panicles 3-8 cm. long; capsule globose, 3-valved, loculicidal, orange or orange-yellow, several together, about 1 cm. long, upon splitting exposing the fleshy scarlet to crimson aril-covered seeds; seeds 1 or 2 in each cell, ellipsoid, erect, about 6 mm. long. In woods and in and along streams in canyons of mts. in the Trans-Pecos, Apr.-June; from Que. to Man., s. to N.E., Ga., Ala., La. and Tex.

3. MAYTENUS MOL.

About 225 species in tropical and warm temperate regions.

1. *Maytenus texana* Lundell. GUTTA-PERCHA, LEATHERLEAF, MANGLE DULCE. A much-branched spreading or prostrate shrub with short thickish minutely puberulent branchlets; leaves alternate, thick, with petioles 1-3 mm. long, pale ashy-gray when dry, oblong-elliptic to elliptic-obovate, broadly obtuse to rounded and usually minutely apiculate at apex, rounded at base, 1.5-3 cm. long, 1-2 cm. wide, entire to often remotely several-toothed, sparsely puberulent, persistent; stipules minute, deciduous; flowers unisexual, yellowish-green, fasciculate in leaf axils; pedicels less than 2 mm. long; calyx lobes rounded, 5-parted, minutely erose-ciliolate, punctate, about 0.65 mm. long; petals 5, spreading, ovate, 1.2-1.5 mm. long, punctate, erose at apex; stamens 5, inserted below annular disk; capsules obovoid, coriaceous, about 12 mm. long; seeds lineate, oblong-obovoid, about 5 mm. long, covered with a red fleshy aril. *M. phyllanthoides* Benth. var. *ovalifolia* Loes. In thickets on clay and sandy-clay mounds and rises in the Brownsville area, also Kleberg and Nueces cos., Jan.-July; also adj. Mex.

4. FORSELLESIA GREENE¹²²

GREASE-BUSH

Small deciduous intricately branched shrubs with slender greenish angled mostly spinescent branches with decurrent lines from the nodes; leaves small, simple, entire, alternate, lanceolate to obovate, pubescent or glabrous, commonly with minute stipules, with 2 to 4 lateral veins parallel to the margin; flowers perfect, regular or nearly so, usually axillary, borne on slender pedicels with reduced scarious bracts at the base; sepals 5 or rarely 4 or 6, ovate, hyaline-margined; petals 5 or rarely 4 or 6, white, narrowly oblanceolate, distinct, deciduous, much longer than the sepals, inserted by a narrow base under the edge of a fleshy crenately 6- to 10-lobed disk; stamens equal or unequal, the longer ones inserted opposite the sepals; carpels 1 to 3, ovate, distinct, attenuate to the stigma, sessile upon the disk; ovary superior, 1-celled with 1 or 2 ovules; fruit an asymmetrical ovoid coriaceous striated follicle that opens along the ventral suture.

A small genus of 8 species in western United States.

1. Petiole with a swollen reddish base that usually produces obvious stipules; leafy branchlets typically erect, straight and elongated . . . 1. *F. planitierum*.
1. Petiole not as above, at most somewhat narrowly keeled, without obvious stipules; branchlets sparsely leafy, typically spreading or recurved-arcuate (2)
- 2(1). Plant with numerous short branchlets that are spinescent at tips; leaves lanceolate to narrowly oblanceolate; petals very narrowly oblanceolate, less than 1 mm. wide; in west and northwest Texas 2. *F. spinescens*.
2. Plant without spinescent branchlets; leaves very broadly oblanceolate; petals lanceolate, about 1.5 mm. wide; endemic in Uvalde and Val Verde cos. 3. *F. texensis*.

1. *Forsellesia planitierum* Ensign. Much-branched spinescent shrubs with numerous straight erect branchlets, 5-12 dm. high; leaves with petioles less than 2 mm. long, narrowly elliptic to oblanceolate, acute, pubescent, prominently venose beneath, 6-12 mm. long, 2.5-4 mm. wide; stipules subulate, to 1 mm. long; pedicels 1-3 mm. long; sepals 5, ovate, 1.5-2 mm. long, 1 mm. wide; petals 5, oblanceolate, 4-6 mm. long, 1.5-2 mm. wide; stamens 8, unequal in length; mature follicles ovoid, 4-5 mm. long. On bluffs, breaks and eroded slopes in the Plains Country, spring; also Okla.

2. *Forsellesia spinescens* (Gray) Greene. Densely and intricately branched shrub to 15 dm. high, the branches angulate, usually glabrous; leaves short-petiolate, oblanceolate, acute, 5-11 mm. long, 1-2.5 mm. wide, glaucous, soon deciduous; flowers subsolitary, axillary, short-pedicellate; sepals usually 5, ovate, 1.5-2 mm. long, hyaline-margined; petals 5, white, oblanceolate to ligulate, 3-7 mm. long, less than 1 mm. wide; stamens 6 to 10; follicles ovoid, coriaceous, asymmetric, acute, about 5 mm. long. *Glossopetalon spinescens* Gray. On rocky hills, ledges, rimrock and in dry washes in the Trans-Pecos, Mar.-July; from Okla. and Tex. to s. Calif. and n. Chih.

3. *Forsellesia texensis* Ensign. Tall closely branched nonspinescent shrub with young flexible branches about 1 mm. in diameter, glabrous, the older branches dark-gray; leaves with petioles about 1 mm. long, very broadly oblanceolate, acute to mucronate, frequently with margins and veins thickened, generally glabrous or with occasional pubescence, 1-2 cm. long, 3-5 mm. wide; pedicels about 5 mm. long, with 4 or 5 scarious bracts at base; sepals 5, entire, ovate, hyaline-margined, about 2 mm. wide; petals lanceolate, 5-7 mm. long, 1.5 mm. wide; stamens 7 to 9, equal; follicles very broadly ovoid, 4-5 mm. long. On chalk bluffs along the Nueces River near Montell, Uvalde Co. and on bluffs of Devils River in Val Verde Co., fall; endemic.

5. SCHAEFFERIA JACQ.

About 16 species from southern United States to the West Indies and South America.

1. *Schaefferia cuneifolia* Gray. DESERT YAUPON, CAPUL, PANALERO. Shrub mostly 1-2 m. high, glabrous, with rigidly and intricately branched somewhat spinescent twigs; bark light-gray; spur branches mere knobs to 2 mm. high; leaves sessile, alternate or fasciculate,

¹²² Based on the treatment by Margaret Ensign in Am. Midl. Nat. 27:501-511. 1942.

exstipulate, cuneate-obovate to oblanceolate, broadly obtuse to shallowly emarginate at apex, 5-23 mm. long, 2-15 mm. wide, glabrous, coriaceous, pale-green to somewhat glaucous; staminate and pistillate flowers on separate plants; flowers solitary or several clustered, unisexual, 4-merous, sessile or with pedicels to 2 mm. long; sepals about 0.5 mm. long; petals greenish, oblong, about 3 mm. long; fruit subglobose, 2-celled, slightly obcompressed, shallowly bisulcate longitudinally between 2 seeds, 3-5 mm. long and wide, 2.5-4 mm. thick, with scanty flesh, orange to bright-red, translucent, shining. On rocky hillsides and breaks and in canyons in the Rio Grande Plains and Valley, and s. Trans-Pecos, Feb.-July; also n. Mex.

6. MORTONIA GRAY

Erect small shrubs; leaves alternate, numerous, persistent, entire, 1-nerved, usually coriaceous with the margins thickened or often revolute; stipules glandlike, caducous; flowers small, white, racemose or cymose with the cymes borne in the upper axils to form a terminal panicle; calyx tube 5-lobed, 10-angled; petals 5, erose-dentate to glandular-ciliolate; stamens 5; ovary imperfectly 5-celled; fruit an achene; seeds oblong, without an aril.

About 8 species in southern United States and Mexico.

1. Leaves oblanceolate, glabrous, leathery, the margins often thickened but not revolute, more than 1 cm. long; in Rio Grande Plains 1. *M. Greggii*.
1. Leaves ovate to oval or suborbicular, scaberulous-hispid to subglabrate, thick-coriaceous, the margins revolute, less than 1 cm. long (2)
- 2(1). Leaves 5-10 mm. long, 2.5-6 mm. wide; flowers many, usually in cymose panicles; widespread in mountains of the Trans-Pecos 2. *M. scabrella*.
2. Leaves 3-5 mm. long, 1.5-2 mm. wide; flowers few, in narrow racemes; rare near and along the Rio Grande in Val Verde Co. 3. *M. sempervirens*.

1. *Mortonia Greggii* Gray. AFINADOR. Erect slender shrub to 2 m. high, the branches puberulent; leaves oblanceolate, tapering at base to short petioles, obtuse-mucronate at apex, 15-25 mm. long, to 5 mm. wide, bright-green, glabrous; flowers about 5 mm. broad, numerous in cymose panicles to 7 cm. long and 5 cm. wide; calyx glabrous, about 3 mm. long, the lobes usually conspicuously scarious-margined; petals white, about 2 mm. long; fruit 4-5 mm. long. In thickets on gravelly hills in Rio Grande Plains, Dec.-May; also n.e. Mex.

2. *Mortonia scabrella* Gray. Yellowish-green shrub to 25 dm. high, usually much lower, densely branched with often elongate brittle rigidly erect branches; leaves short-petiolate, spreading or ascending, ovate to mostly oval or broadly elliptic, sometimes suborbicular, 5-10 mm. long, 2.5-6 mm. wide, rounded to bluntly acute at apex, scaberulous-hispidulous, very thick with the margins revolute; flowers about 5 mm. broad, mostly in terminal cymes 2-4 cm. long; calyx hirtellous, about 2 mm. long, the lobes rounded-deltoid; petals creamy-white, obovate-oblong, about 2 mm. long; fruit short-cylindroid, 4-5 mm. long, about 2 mm. thick. On rocky slopes, ridges, ledges and about rimrock in the Trans-Pecos, Feb.-Sept.; from Tex. to Ariz. and n. Mex.

3. *Mortonia sempervirens* Gray. Stiff intricately branched shrub about 6 dm. high; leaves bright grass-green, oblong-elliptic, usually recurved-ascending, shortly petiolate and mucronate at the subobtusate to acute apex, 3-5 mm. long, 1.5-2 mm. wide, glabrous (*fide* Gray) to more commonly minutely and sparsely hispidulous; flowers in narrow racemes about 1 cm. long, otherwise similar to those of *M. scabrella* but slightly smaller. On rocky hills and ledges near and along the Rio Grande in Val Verde Co., Apr.-May; undoubtedly also in adj. Mex.

FAM. 108. ACERACEAE JUSS.

MAPLE FAMILY

Trees and shrubs with watery saccharine sap, polygamo-dioecious; leaves opposite, simple and palmately lobed or pinnately divided; flowers small, regular, with or without petals; ovary 2-celled, 2-lobed; ovules 2 in each cell.

Three genera comprising about 200 species in the North Temperate Zone and tropical mountains.

I. ACER L. MAPLE

Deciduous trees or rarely shrubs; flowers mostly 5-merous, in racemes, panicles or corymbs; calyx colored, 5 (rarely 4 to 12)-lobed or -parted; petals either none or as many as the lobes of the calyx, equal, usually with short claws, inserted on the margin of a perigynous or hypogynous disk; stamens 3 to 12; ovary 2-celled, with a pair of ovules in each cell; styles 2, long and slender, united only below, stigmatic down the inner side; back of each carpel bearing a wing, converting the fruit into two 1-seeded eventually separable samaras or "keys."

Nearly 200 species in the Northern Hemisphere.

- 1. Leaves compound, with 3 to 9 pinnately veined leaflets 1. *A. Negundo*.
- 1. Leaves simple, palmately veined and mostly palmately lobed (2)
- 2(1). Distribution in canyons of the Edwards Plateau and of Trans-Pecos Texas 2. *A. grandidentatum*.
- 2. Distribution in the forests of east Texas (3)
- 3(2). Uncommon on forested hills and ravines of northeast Texas; leaf margins smooth; samaras 25-40 mm. long 3. *A. saccharum*.
- 3. Widespread in swamps and along streams in alluvial or flat woods in southeast Texas, rarely extending into northeast Texas; samaras very rarely more than 25 mm. long (4)
- 4(3). Leaf margins smooth, not closely serrate; terminal and upper lateral lobes of leaf with straight or concave sides, the lobes somewhat quadrate or squarish; base of sinus between lobes forming a rounded or obtuse angle; the yellowish flowers and fruits produced along with the leaves or after they develop; calyx bearded; fruit more or less pubescent 4. *A. barbatum*.
- 4. Leaf margins more or less closely serrate; terminal and/or at least the upper lateral lobes of the leaf with gradually rounded or tapering sides, the lobes triangular; base of sinus between lobes forming an acute angle; the reddish flowers and fruits produced before leaves develop; calyx and fruit glabrous 5. *A. rubrum*.

1. *Acer Negundo* L. BOXELDER, ASH-LEAVED MAPLE, ARCE, FRESNO DE GUAJUCO. Small tree with green pubescent to glabrous twigs and branchlets; leaves pinnate, with 3 to 9 petiolulate very veiny and more or less pubescent leaflets, when mature pubescent to glabrate beneath; leaflets 5-10 cm. long and 5-7.5 cm. wide; terminal leaflet elliptic to obovate; lateral leaflets narrower and coarsely few-toothed or entire; leaves of vigorous tips and sprouts with more numerous often lobed leaflets; flowers greenish, unisexual, produced just before the leaves, the staminate flowers fascicled and pendulous on filiform pedicels, the pistillate flowers racemose; petals and disk absent; samaras 25-35 mm. long, yellowish, strongly ascending, the seed prolonged. *Rulac Negundo* (L.) Hitchc. River banks, floodplain woods, waste places, fencerows mainly in the e. half of Tex., Feb.-Apr.; from Fla. to Tex., n. to w. N.E., N.Y., s. Ont. and s.e. Minn.; much cult. and naturalized e. to Maritime Provinces and e. Que.

Those trees with the branchlets more or less permanently puberulent are usually segregated as var. *texanum* Pax.

2. *Acer grandidentatum* Nutt. SUGAR MAPLE, BIGTOOTH MAPLE, PALO DE AZÚCAR. Tree to 15 m. high, with dark-brown scaly bark; branchlets glabrous; thickish leaves with stout petioles 3-5 cm. long, 3- to 5-lobed, with broad sinuses, 5-9 cm. wide, cordate to truncate at base, the lobes obtuse to acute and somewhat lobulate or very rarely entire, glaucescent and pubescent beneath mainly along the veins; flowers on slender drooping

villous pedicels in several-flowered short-stalked or nearly sessile corymbs; calyx often persistent under the fruit; corolla absent; wings spreading, often rose-colored in mid-summer, the wings to 25 mm. long, with the nutlets about 8 mm. long. *A. saccharum* var. *grandidentatum* (Nutt.) Sarg. In canyons of the Edwards Plateau and of the mts. in the Trans-Pecos, Mar.-Apr.; from Tex. to Wyo., Ut., N.M. and n. Mex.

Those plants with wings of the samara 15 mm. long or less and with smaller, less toothed leaves are usually referred to var. *brachypterum* (Woot. & Standl.) E. J. Palm. Although typical *A. grandidentatum* is found in the Sabinal Canyon, most of the material found in the canyons of the Edwards Plateau falls into var. *sinuosum* (Rehd.) Little, characterized by having the leaf divided into 3 large usually entire lobes.

Acer nigrum Michx. has been reported as occurring in west Texas but no specimens of this species have been seen from the state. This report might have been based on a misdetermination of *A. grandidentatum* which it superficially resembles.

3. *Acer saccharum* Marsh. SUGAR MAPLE, ROCK MAPLE. Large tree to 40 m. high, with spreading branches to form a conical crown and new brown branchlets, the older gray bark becoming deeply furrowed; leaves 3- to 5-lobed, to 15 cm. across, more or less cordate at base, the lobes acuminate, sparingly coarsely toothed with narrow and deep sinuses, dark-green above, glabrous and pale or somewhat glaucous beneath; flowers in subsessile corymbs, expanding with the leaves, campanulate, about 5 mm. long, greenish-yellow, on slender hairy pedicels 3-7 cm. long; corolla absent; stamens exerted in staminate flowers; style branches 5-6 mm. long; samaras 2.5-4 cm. long, the seeds 8-12 mm. long, the ascending wings 6-10 mm. broad. On forested hills and in ravines in n.e. Tex., Mar.-May; from e. Can. to e. Man., s. to Ga., Ala., Miss., Ark. and Tex.

The leaves turn yellow to scarlet in autumn. Its wood is highly valued and, in Canada and northeastern United States, it is one of the chief sources of maple syrup and sugar.

4. *Acer barbatum* Michx. FLORIDA MAPLE, SOUTHERN SUGAR MAPLE. Tree to 20 m. high, with thin whitish-gray smooth bark that becomes furrowed in age, the trunk to 7 dm. in diameter; branchlets grayish and purple-tinged, glabrous to short-pilose; leaves with glabrous to pilose petioles to 75 mm. long, 3- to 5-lobed, minutely pilose to glabrescent and somewhat glaucescent beneath, to 9 cm. long and 11 cm. broad, truncate to subcordate at base, with entire or slightly lobulate obtuse to acute lobes; flowers yellowish-green, with pedicels elongating to 5 cm., in many-flowered nearly sessile corymbs; calyx to 2.5 mm. long, with a conspicuous long white beard projecting from throat; corolla absent; ovary long-setose; samaras 1.5-3 cm. long, fruit body to 1 cm. long, sparingly villous while young, the wings to 9 mm. wide. *A. floridanum* (Chapm.) Pax, *A. saccharum* var. *floridanum* (Chapm.) Small & Heller. Along streams and in flat woodlands in s.e. Tex., Mar.-Apr.; from Fla. to s.e. Tex., n. to e. Va. and s.e. Mo.

This species might be considered as a small edition of *A. saccharum* since the two are undoubtedly closely related.

5. *Acer rubrum* L. RED MAPLE, SCARLET MAPLE. Tree to about 35 m. high, with spreading to ascending smoothish branches to form a globular crown, the trunk to about 1 m. in diameter; branchlets red; leaves with mostly reddish petioles to 1 dm. long, 3- to 5-lobed, to 1 dm. long and wide, the margins coarsely serrate, broadly cuneate to rounded or subcordate at base, the lobes triangular-ovate and short-acuminate, herbaceous to somewhat coriaceous, dark-green and lustrous above, glaucous and subglabrous to densely whitish- or tawny-pubescent beneath, mostly always pubescent on veins beneath; flowers appearing before the leaves, usually reddish, on slender stalks; petals linear-oblong, about 2 mm. long; samaras 15-25 mm. long, on pendulous stalks to 1 dm. long, glabrous, the fruit body about 8 mm. long, the wings to about 12 mm. wide. Usually in swamps, along streams or in alluvial woods in e. Tex., Feb.-Apr.; from Fla. to Tex., n. to Man. and e. Can.

The var. *rubrum* has, at most, hairs along the nerves on the lower surface of the leaves, whereas the var. *Drummondii* (H.&A.) Sarg. and var. *trilobum* K.Koch have the lower surface of their leaves densely and usually permanently hairy. In addition, the leaves of var. *trilobum* have only three well-developed lobes, with the smaller lateral basal lobes being suppressed.

FAM. 109. HIPPOCASTANACEAE DC.

BUCKEYE FAMILY

Trees or shrubs with exstipulate opposite palmately divided leaves, the leaflets pinnately straight-veined; perfect and unisexual flowers on same plant, in a large terminal panicle, irregular, showy; petals 5 or sometimes 4, brightly colored or whitish, unguiculate; fruit a leathery capsule, 3-celled and 2- or 3-seeded or (by abortion) 1-seeded, smooth or warty to spiny.

A family of two genera, *Billia* of Latin America, and the present Temperate Zone genus.

I. AESCULUS L.¹²³

BUCKEYE. HORSE-CHESTNUT

Shrubs to large trees; leaves deciduous, with 5 to 11 leaflets; flowers mostly with imperfect pistils and sterile; pedicels jointed; calyx campanulate to tubular, somewhat irregularly 5-lobed, often oblique or gibbous at base; petals more or less unequal, with claws, nearly hypogynous; stamens usually 7 or rarely 5, 6 or 8; filaments long, slender, often unequal in length; anthers elliptical, glandular-apiculate, 2-celled, opening longitudinally; style one; ovary 3-celled; seeds large, with a dull or shining thick coat and a large round pale scar.

About a dozen species in Eurasia and North America.

- 1. Calyx about 6 mm. long; petals subequal, villous-ciliate or dorsally glandular but not on margins; stamens exerted to almost twice the corolla length; flowers pale-yellow to greenish-yellow; fruit spiny or rarely smooth (2)
- 1. Calyx rarely less than 8 mm. long; petals unequal, the upper pair longer and narrower with minute spatulate blade and the claw often equaling the lateral petals; lateral petals with a wide and nearly rounded blade, with stipitate glands on margins; stamens included or only slightly exerted beyond the uppermost petals; flowers red or yellow, sometimes with these colors mixed; fruit smooth; leaflets 5 or rarely 7 (3)
- 2(1). Leaflets 7 to 111. *A. arguta*.
- 2. Leaflets 5 or very rarely some leaves with 6 or 72. *A. glabra*.
- 3(1). Flowers scarlet or yellow-red; primarily in the eastern half of Texas3. *A. Pavia* var. *Pavia*.
- 3. Flowers yellow throughout; confined to the Edwards Plateau3. *A. Pavia* var. *flavescens*.

1. *Aesculus arguta* Buckl. WHITE BUCKEYE. Large shrub or small tree to 7 m. tall, with a trunk to 15 cm. in diameter; bark smooth, gray, somewhat scaly with thin plates; leaves with a petiole to 1 dm. long; leaflets 7 to 11, sessile or shortly petiolulate, lanceolate to elliptic-lanceolate, tapering at base, acute to long-acuminate at apex, glabrous on upper surface, subglabrous to tomentose on lower surface, the margins sharply and unequally serrate, to 12 cm. long and 4 cm. wide; calyx campanulate, rarely more than 6 mm. long, the short lobes rounded to acute; corolla to 15 mm. long. *A. glabra* Willd. var. *arguta* (Buckl.) Robins., *A. glabra* var. *Buckleyi* Sarg., *A. Buckleyi* (Sarg.) Bush. Commonly in sandy soils in woods, thickets, along streams and in fencerows in n.e. and cen. Tex., Mar.-Apr.; from n.e. Kan., s. to cen. Tex.

Plants are occasionally found that are apparently hybrids of this species and *A. pavia*. This is evidenced by their intermediate leaflet size and floral coloration.

2. *Aesculus glabra* Willd. OHIO BUCKEYE. Tree to 10 m. tall; bark gray, much-furrowed and broken into scaly plates; leaves compound, with petioles 10-15 cm. long; leaflets usually 5, elliptic to obovate, more or less abruptly acuminate, narrowed at base, 7.5-13 cm. long, finely toothed; flowers in branched clusters 10-15 cm. long, showy, to about 3 cm. long, pale greenish-yellow, with villous-ciliate petals nearly equal in length; capsule to 5 cm. in diameter, prickly, with 1 or 2 poisonous seeds that are to

¹²³ Ref.: J. W. Hardin in Brittonia 9:173-195. 1957.

35 mm. wide. In woodlands and bottomlands in n.e. Tex. (*vide* Small), Mar.-May; primarily in the Ohio and Miss. Valley.

3. *Aesculus Pavia* L. Large shrub or tree to 10 m. tall; with a trunk to 5 dm. in diameter; bark smooth, gray or brownish; leaves with a petiole to 15 cm. long; leaflets essentially sessile or with a petiolule to 1 cm. long, lanceolate to elliptic or oblanceolate, tapering at base, more or less abruptly acuminate at apex, glabrous or sometimes tomentose on lower surface, the margins irregularly serrate or crenate-serrate, to 17 cm. long and 7 cm. wide; calyx 8-16 mm. long, very rarely shorter tubular or sometimes tubular-campanulate, with a gibbous base, the short lobes rounded; corolla to 3 cm. long. Incl. var. *discolor* (Pursh) T.&G., *A. discolor* Pursh, *A. austrina* Small, *A. discolor* var. *mollis* (Raf.) Sarg. Commonly in forests, along streams, in thickets and on rocky hills in the e. half of Tex., Mar.-May; from e. N.C., s. to n. Fla., w. to s. Ill., s.e. Mo., Ark. and Tex. We have two varieties.

The red-flowered var. *Pavia* (RED BUCKEYE) occurs frequently in east Texas but is rare south to Victoria County and on the eastern edge of the Edwards Plateau. The calyx is typically elongated and narrowly tubular but rarely it is rather short and somewhat campanulate. The margin of the orifice is glandular-ciliate but these adornments are sometimes obscured by long silky hairs.

Var. *flavescens* (Sarg.) Correll. This yellow-flowered plant is the representative of this species throughout most of the Edwards Plateau. It has been found as far west as Edwards and Kinney counties. Although flower color, in itself, is not sufficient reason for segregating a plant, the apparent geographic separation of the yellow-flowered plant from the red-flowered var. *Pavia* would seem to justify this distinction: We have not seen the yellow-flowered plant in Texas other than on the Edwards Plateau. On the eastern edge of the Edwards Plateau, especially in Hays, Kendall, Comal and Bexar counties, where var. *Pavia* and var. *flavescens* come together, plants are frequently found that have yellow flowers that are deeply tinged or marked with red.

FAM. 110. SAPINDACEAE JUSS.

SOAP-BERRY FAMILY

Trees, shrubs or vines; leaves always alternate (in ours), with or without stipules, simple or palmate to pinnate or odd-pinnate; staminate and pistillate flowers on separate plants or often some flowers appearing perfect; flowers regular or irregular, usually borne in racemes, panicles or cymes; sepals 4 or 5; petals commonly 4 or 5, often with scaly or hair-tufted nectaries on lower inner side; stamens usually more numerous than petals, typically 8 or 10 in 2 whorls; anthers 2-celled; fruit a berry or capsule, sometimes a schizocarp of samaralike mericarps.

About 150 genera and about 2,000 species, mostly in tropical Asia and America. Species of *Koelreuteria*, or China Tree, are cultivated in south Texas but they apparently do not escape from cultivation.

- 1. Flowers regular; leaves pinnate, the terminal leaflet absent 1. *Sapindus*, p. 1006.
- 1. Flowers irregular; leaves odd-pinnate with a terminal leaflet (2)
 - 2(1). Erect shrubs or small trees; flowers with 4 or 5 petals and 2 ovules in each cell 2. *Ungnadia*, p. 1006.
 - 2. Shrubby or herbaceous climbers; flowers with 4 petals and solitary ovules in each cell (3)
 - 3(2). Inflorescence umbelliform, with branches mostly about 1 cm. long; fruits 3-lobed and inflated, membranaceous, dehiscent, more or less acute at apex 3. *Cardiospermum*, p. 1006.
 - 3. Inflorescence racemose or paniculate, the branches longer than above; fruit consisting of 3 indehiscent samaras or 3-winged capsules, often notched at apex (4)
 - 4(3). Samaras seed-bearing in the middle; leaves minutely stipulate, trifoliolate 4. *Urvillea*, p. 1007.
 - 4. Samaras seed-bearing at apex; stipules obsolescent; leaves more dissected than above 5. *Serjania*, p. 1007.

I. SAPINDUS L. SOAP-BERRY

About 13 species in America and Asia.

1. *Sapindus Saponaria* L. var. *Drummondii* (H. & A.) L. Benson. JABONCILLO. Trees to about 15 m. high under optimum conditions, usually less than 10 m. high, with rough grayish or tan bark and yellow wood; leaves alternate, exstipulate, pinnate; leaflets as many as 18, elliptic-lanceolate to narrowly lanceolate-attenuate, acuminate, falcate, strongly veined on upper surface, to 1 dm. long and 4 cm. wide, entire; flowers 4-5 mm. broad, regular, white, in large dense terminal panicles; sepals and petals 4 or 5, with ciliate margins; petals usually 5, appendaged; stamens 8 or 10, with long hairs on the filaments; fruits globose, about 13 mm. in diameter, consisting of amber or yellowish translucent flesh surrounding the seed. *S. Drummondii* H. & A., *S. marginatus* of Coult. Commonly forming groves in fields and on the edge of woods, along streams and fencerows, scattered throughout Tex., Mar.-July; from La., n. to Kan., w. to N.M. and Mex.

2. UNGNADIA ENDL. TEXAS BUCKEYE. MEXICAN BUCKEYE

A monotypic genus.

1. *Ungnadia speciosa* Endl. MONILLA. Shrub or small tree, rarely to 10 m. high, with a trunk to 2 dm. in diameter, the thin bark light-gray; leaves alternate, odd-pinnate, exstipulate; leaflets 3 to 7, ovate to ovate-lanceolate, acuminate, serrate, to 12 cm. long and 4 cm. wide, pubescent beneath when young but soon glabrate; flowers in lateral fascicles, appearing before or with the leaves from the axils of the preceding season, pink to purplish-pink, fragrant; calyx deeply 5-lobed; petals 4 or 5, obovate, with a pilose claw, fimbriate-crested at apex of claw on inner side, to 1 cm. long; stamens 7 to 10; anthers cherry-red in color; fruit a large somewhat woody stipitate 3-lobed smoothish pod, pale-green, often suffused with red, 3.5-5 cm. thick; seeds spherical, 1-1.5 cm. in diameter, dark-brown to blackish, poisonous. Commonly in rocky areas in canyons and on slopes and ridges in s., cen. and w. Tex., e. to Dallas Co., Mar-June; also N.M. and adj. Mex.

3. CARDIOSPERMUM L. HEARTSEED. BALLOON-VINE

Mostly herbaceous climbers, with alternate twice-ternate to variously decompound leaves; leaflets entire to toothed or incised; flowers small, yellowish or whitish, in axillary racemose-paniculate or corymbose clusters on a slender peduncle and with 2 tendrils at the apex of the rachis; sepals 4 or 5, the 2 outer ones smaller than the inner ones; petals 4, stamens 8; fruit a membranaceous 3-lobed 3-celled inflated pod.

About 14 species, mostly in tropical America.

1. Leaflets dissected into linear-oblong segments that are to 1 cm. long and 4 mm. wide; sepals 5 1. *C. dissectum*.
1. Leaflets ovate-lanceolate to narrowly lanceolate, coarsely dentate and incised, the complete blade much more than 1 cm. long and 4 mm. wide; sepals 4 (2)
- 2(1). Vegetative parts sparsely pilose to subglabrous; peduncle, tendrils and the 3 verticillate floral branchlets all filiform; seed scar lunate, about 5 mm. long or the diameter of the seed 2. *C. Halicacabum*.
2. Vegetative parts (especially lower surface of leaflets) densely villose; peduncle, tendrils and the several floral branchlets all stout; seed scar suborbicular, at most notched, 2-3 mm. in diameter 3. *C. corindum* f. *villosum*.

1. *Cardiospermum dissectum* (Wats.) Radlk. Stems wiry, herbaceous, several-ribbed, sparsely hirsute to essentially glabrous; leaves to 1 dm. long, decompound and much-dissected, thinly hispidulous and ciliate, the rachis and petiolules winged or margined throughout; flowers several in a short contracted panicle; calyx puberulent, the elliptic-obovate inner sepals about 6.5 mm. long and conspicuously long-ciliate on the lower half; petals elliptic, about 5 mm. long; fruit somewhat quadrangular-obovate in outline,

glabrous, lustrous, about 15 mm. long and twice as wide. In gravelly soil on open-brushy hills in extreme s. Tex., July-Sept.; also Chih.

2. *Cardiospermum Halicacabum* L. COMMON BALLOON-VINE, FAROLITOS. Vine, sparsely pilose to subglabrous throughout; stem wiry, several-ribbed; leaves usually biternate; leaflets ovate-lanceolate to rhombic-lanceolate or narrowly lanceolate, acuminate at apex, decurrent on petiolules, incisely lobed and toothed, to about 8 cm. long and 3 cm. wide; flowers about 4 mm. long; petals obovate; fruit 3-4.5 cm. in diameter; seeds black, 5 mm. in diameter. Sprawling on ground and trailing over weeds and bushes in open waste ground or brushy areas in n.e., cen. and s. Tex., June-Nov.; widespread in warmer regions of the W. Hemis.

3. *Cardiospermum corindum* L. f. *villosum* (Mill.) Radlk. TROPICAL HEARTSEED. Vine, very similar to *C. Halicacabum* except for its typically smaller leaf segments, villous vestiture, difference in the inflorescence, somewhat larger (4-6 mm. long) flowers and different seed scar. *C. molle* of Coult. Uncommon in waste lands, brushlands and open woods in w. and s. Tex., Apr.-Aug.; throughout warmer regions in the W. Hemis.

4. URVILLEA H.B.K.

About 13 species primarily in tropical America.

1. *Urvillea ulmacea* H.B.K. APAAC. Shrubby climber, with alternate stipulate 3-foliolate leaves; stems wiry, hirsute with white incurved hairs; leaflets petiolulate, ovate to ovate-lanceolate, acuminate at apex, at base slightly decurrent on the petiolule and rounded to broadly cuneate or subcordate, to 1 dm. long and 5 cm. wide, coarsely dentate and somewhat incised, softly pubescent beneath; flowers whitish or yellowish-green, in axillary racemose panicles on a more or less elongated peduncle and with 2 coiled tendrils at the apex of the rachis; sepals 5, the 2 outer rounded ones smaller than the inner elliptic ones; petals 4, obovate, about 1.5 mm. long, twice as long as the hair-tufted clublike nectary at the base of each petal; stamens 8; fruit composed of 3 broadly winged membranaceous samaras that are seed-bearing in the middle, elliptic-oval in outline, 2-3 cm. long at maturity, narrowed at base, pubescent to glabrate; seed one in each cell. *U. mexicana* Gray. In woodlands and waste places in extreme s. Tex., May-Oct.; also adj. Mex., s. to Peru and Arg.

5. SERJANIA MILL.

Woody vines with alternate exstipulate ternate or odd-pinnate leaves and axillary racemes or panicles of small yellowish or whitish flowers, commonly with 2 tendrils at the apex of the floral rachis; sepals 5, imbricated, concave, the outer 2 smaller than the inner ones; petals 5; stamens 8; fruit composed of 3 broadly winged dorsally attached membranaceous samaralike mericarps that are seed-bearing at their apex, the wings usually produced beyond the axis to make the fruit notched at the apex.

About 215 species mainly in tropical America.

1. Fruits broadest below middle, about 10 mm. long, the wings lenticular; petals oblanceolate to spatulate, 2-2.5 mm. long, scarcely exceeding the nectary; sepals white-pubescent1. *S. brachycarpa*.

1. Fruits broadest above middle, to about 35 mm. long, the wings inflated; petals obovate, about 4 mm. long, twice as long as the nectary; sepals glabrate or puberulent2. *S. incisa*.

1. *Serjania brachycarpa* Gray. Stems wiry, several-ribbed, hirsute, often high-climbing; leaflets ovate to ovate-lanceolate, mucronulate, remotely and coarsely serrate, more or less shortly hirsute above and softly pubescent beneath, 1.5-5 cm. long, to 25 mm. wide, the terminal leaflet cuneate-tapering into a petiolule, the lateral leaflets essentially sessile; flowers greenish-yellow, in a thyrse; petals oblanceolate to spatulate, 2-2.5 mm. long, only slightly longer than the conspicuous platelike hairy nectary at the base of each petal; fruit 1-1.3 cm. long, puberulent to glabrate, cordate-ovate on outline, the wings 3.5 mm. wide. In thickets and scrub forests along and near the coast in s. and s.w. Tex. winter and spring; also adj. Mex.

2. *Serjania incisa* Torr. Stem hirtellous or glabrate; leaflets ovate-rhombic, incised-serrate or coarsely dentate, noticeably darker green on upper surface, pubescent or puberulent on both surfaces, acute at each end, 25-35 mm. long; flowers in racemiform panicles; outer sepals glabrate, the inner ones puberulent; petals obovate, 4 mm. long, about twice as long as the basally attached nectary; fruit to 35 mm. long and 2 cm. wide, at first pubescent, at length nearly smooth, from obovate-oblong to cuneate in outline, the seed-bearing portion reticulately veined, the wings 6-10 mm. wide. In the Rio Grande Plains and w. Edwards Plateau; also Coah.

FAM. 111. BALSAMINACEAE A. RICH. TOUCH-ME-NOT FAMILY

Herbs or undershrubs with bland watery juice; leaves alternate, opposite or rarely whorled, simple, exstipulate; flowers irregular, perfect, hypogynous; calyx petaloid, imbricated, spurred; stamens 5, with short flat filaments and introrse more or less connivent obconic anthers; ovary 5-celled; fruit a capsule or berry; seeds without albumen.

About 500 species in 4 genera, mostly in the tropics of Asia and Africa.

1. IMPATIENS L. TOUCH-ME-NOT. JEWEL-WEED. BALSAM

About 650 species, nearly all of which are in the Old World.

1. *Impatiens capensis* Meerb. SPOTTED TOUCH-ME-NOT. Succulent annual, glabrous, bright-green, to 15 dm. high, the stems simple or freely branched; leaves with petioles to 1 dm. long, broadly ovate to ovate-elliptic, obtuse-mucronate at apex, broadly cuneate to rounded at base, pale or glaucous beneath, to 12 cm. long and 8 cm. wide, coarsely crenate-mucronate; flowers axillary or paniced, often both normal and cleistogamous flowers produced; bracts of inflorescence linear-subulate; flowers 2-3 cm. long, pendulous on filamentous pedicels to about 2 cm. long, usually orange-color with crimson spots; sepals apparently 4, the anterior sepal notched at the apex, the large posterior saccate sepal longer than broad and its spur one third to half its length and bent back parallel with it; petals 3, bilobed; filaments appendaged with a scale on the inner side, the 5 scales connivent over the stigma; capsules about 2 cm. long, the 5 valves coiling elastically and dehiscing explosively when touched or shaken. *I. biflora* Walt. In moist woods, along streams and in springy places in open or shade in e. Tex., May-July; from Nfld. and Que. to Alas., s. to Fla. and Tex.

The yellow-flowered *I. pallida* Nutt. occurs in east-central Oklahoma. It should be looked for in northeast Texas.

FAM. 112. RHAMNACEAE JUSS.* BUCKTHORN FAMILY

Shrubs or small trees or woody vines or lianes; leaves opposite or alternate, seasonally deciduous, petiolate; stipules present, minute, caducous; flowers perfect except in a few species of *Rhamnus*, in cymes or small thyrses or umbels, or reduced to solitary flowers or appearing glomerate on short shoots, perigynous (or in a few species at early anthesis appearing epigynous because of the almost complete covering of the ovary by the disk), small, inconspicuous (except in *Ceanothus*), usually greenish or yellowish-green, with a hemispherical or campanulate floral cup at whose margins are borne (4 or) 5 triangular sepals, usually (4 or) 5 clawed or spatulate delicate often cucullate petals (these absent in some species) and (4 or) 5 stamens that are opposite the petals and alternate with the sepals and whose anthers are often partly hooded by the ends of the spatulate petals; disk usually present, fleshy or thin or firm, either annular and attached near the rim of the cup or lining the cup or in some species nearly filling the cup and often nearly hiding the ovary in the early stages of its development but not adhering to the ovary or adhering only to the basal portion of it at maturity; style solitary; ovary 1- to 4-celled, each cell

* Cf. M. C. Johnston in C. L. Lundell, *Flora of Texas* II: 357-392. 1969 for a more detailed treatment.

with one anatropous ovule; ovule attached at the base of the cell near the axis; fruit a drupe with 1, 2 or 3 stones or a schizocarpous capsule, in one genus (*Colubrina*) a partially spurious fruit in which the remains of the cup and disk (adherent to the base of the capsule) also partake of the dehiscence.

A family of more than 45 genera and about 600 species, widespread in the warmer parts of the world; easily distinguished as woody plants with the stamens alternate with the sepals.

1. Leaves opposite (2)
1. Leaves alternate or often fasciculate, when opposite (in *Ceanothus Greggii*) without spinescent twigs and with leathery leaves less than 1 cm. wide (3)
- 2(1). Unarmed shrubs; fruits drupaceous9. *Karwinskia*, p. 1015.
2. Twigs thorn-tipped; fruits capsular3. *Adolphia*, p. 1011.
- 3(1). Woody vine or liane, unarmed; fruits about twice as long as broad5. *Berchemia*, p. 1012.
3. Shrubs or small trees; fruits usually about as long as broad (4)
- 4(3). Fruit a 1- to 3-stoned indehiscent drupe (5)
4. Fruit capsular, essentially dry at maturity (8)
- 5(4). Fruit with 2 or 3 stones (6)
5. Fruit with solitary stone (7)
- 6(5). Flowers aggregated in more or less elaborate inflorescences terminating branches6. *Sageretia*, p. 1012.
6. Flowers in few-flowered axillary cymes4. *Rhamnus*, p. 1011.
- 7(5). Petals present; disk thickened around the ovary and partly hiding it in the early stages of anthesis7. *Ziziphus*, p. 1012.
7. Petals absent (except in *C. ericoides*); disk thin, if thickened at all then slightly near the rim of the floral cup8. *Condalia*, p. 1013.
- 8(4). Remains of cup and disk adhering to the base of the ovary at maturity and partaking of the more or less irregular dehiscence of the exo- and mesocarp1. *Colubrina*, p. 1009.
8. Cup and disk persistent on the pedicels at maturity, neatly separating from the parts of the fruit when they fall2. *Ceanothus*, p. 1010.

1. COLUBRINA BRONGN. SNAKEWOOD

Unarmed shrubs or small trees; leaves alternate, ovate, thinly tomentose (sparsely so above), usually with 3 principal nerves (only 1 in *C. texensis*); disk copious, overflowing the cup and essentially hiding the ovary at early stages of anthesis; petals present; ovary cells 3, rarely 4; fruit a slow-maturing hard capsule, the stony endocarp eventually dehiscing both septicidally and at least partly loculicidally releasing the seeds, this accompanied by more or less regular breaking up of the meso- and endocarp and of the remains of the postantheically accrescent disk and cup which adhere to the exocarp of approximately the lower third of the fruit, the entire process of dehiscence delayed for as much as 14 months after anthesis.

About 30 species, 21 of which occur in the New World, one in Hawaii, the remainder in Madagascar and southeast Asia.

1. Flowers appearing solitary or usually glomerate at short twiglike spur-shoots (the latter with numerous crowded nodes; flowers appearing in spring, each one in the axil of one of the nodes, thus glomeruled)3. *C. texensis*.
1. Flowers in axillary cymes or thyrses (2)
- 2(1). Inflorescence (including peduncle) at anthesis about 10 mm. long; leaves 3-6 cm. long, 2-4 cm. broad2. *C. stricta*.
2. Inflorescence (including peduncles) at anthesis 15-30 mm. long; leaves 5-23 cm. long, 3-11 cm. broad1. *C. Greggii*.
1. *Colubrina Greggii* Wats. MANZANITA. Shrub or small tree; leaves 5-23 cm. long, ovate, usually long-tapered to the acute apex, marginally serrate; cymes or thyrses usually

relatively elaborate, 15-30 mm. long, with 15 to 40 flowers; peduncles 5-20 mm. long. Rare in groves of sabal palms s.e. of Brownsville on the Rio Grande delta, summer-fall. Our plants are of the typical variety which otherwise occurs from Coah., s. to Hgo. and Ver. The var. *yucatanensis* M. C. Johnst. occurs in the Yuc. peninsula and Petén.

2. *Colubrina stricta* M. C. Johnst. Shrub; leaves 3-6 cm. long, 2-4 cm. broad, about 1 to 1.5 times as long as broad, apically rounded to acute; cymes or thyrses 10-13 mm. long, with 6 to 15 flowers; peduncles 2-8 mm. long. Rare near a spring in Comal Co., Edwards Plateau, not collected in the U.S. since 1851, late spring or early summer; otherwise known from one locality in N.L. (Lampazos in 1937) and one in Coah. (Muzquiz in 1935).

3. *Colubrina texensis* (T.&G.) Gray. Rounded shrub 1-2 m. tall; leaves the smallest of our Colubrinas, both the lateral veins and the marginal serrations suppressed to some extent; flowers solitary or few in glomerules, never in cymes. Locally abundant in Rio Grande Plains, infrequent n. to s. part of n.-cen. Tex. and s. part of Plains Country, rare in e. part of Trans-Pecos, late spring to early summer. Our plants are of the typical variety that occurs from Tex. s. to Coah., N.L. and Tam. The var. *pedunculata* M. C. Johnst., in which the flowers are in minute cymes, occurs in Coah. and Dgo.

2. CEANOTHUS L.

Armed or unarmed shrubs, sometimes weak, spindly, almost suffruticose; leaves opposite or alternate, 1- to 3-nerved basally, usually serrate; flowers relatively showy for the family, white, in elaborate sometimes umbelliform inflorescences either terminal on leafy branches or terminal on long nearly leafless axillary peduncles, often not only the petals white but also the whole exterior of the flower including portions of the peduncle; ovary 3- (4-) celled; fruit a capsule that dehisces septicidally and also partly loculicidally (along the ventral-axial angles of the 3 parts), the parts abscising from the post-anthetically accrescent cup and disk in which they are borne, the cup and disk persistent on the pedicel as a subtriangular pedestal.

A genus of about 55 species confined to North America and Central America. Some of the Mexican and Californian species have been extensively cultivated, and are usually known as French lilacs.

1. Leaves and branches opposite; much-branched low shrubs of Trans-Pecos mountains
.....1. *C. Greggii*.

1. Leaves alternate (2)

2(1). Low shrubs of Trans-Pecos mountains, with at least some of the branches thorn-tipped
.....2. *C. Fendleri*.

2. Branchlets never thorn-tipped; nearly suffruticose low shrubs of prairies, scrub or forests (3)

3(2). Leaves ovate to occasionally broadly elliptic, acute or rarely not, pilose above; peduncles elongate, mostly axillary, naked or few-bracted at summit
.....3. *C. americanus* var.

Pitcheri.

3. Leaves narrowly elliptic or elliptic-lanceolate, obtuse to barely acute, glabrous or nearly glabrous above; peduncles short, mostly terminating regular leafy branches
.....4. *C. herbaceus*.

1. *Ceanothus Greggii* Gray. Shrub 1-2 m. tall, with small leathery opposite leaves and showy vernal masses of white flowers. Arid mt. slopes in the Trans-Pecos, spring; from Oax. to Tex.

2. *Ceanothus Fendleri* Gray. Low shrub mostly not surpassing 1 m. in height; leaves alternate, small, with some close glandular serrations; branches often bluish-gray or glaucous, with some ordinarily thorn-tipped; flowers in showy masses. High elevations in the Trans-Pecos, Apr.-Aug.; from S.D. and Colo. to Chih. and Coah.

3. *Ceanothus americanus* L. var. *Pitcheri* T.&G. REDROOT, NEW JERSEY TEA. Low shrub, the flowering branches being vernal innovations of the same season (thus plants approaching suffruticose in habit); leaves more or less pilose above and below, rarely

glabrous, the apex usually pointed; peduncles long, axillary, naked below. Usually sandy soil, forests and forest-openings and prairies, e., s.e., n.-cen. and s.-cen. Tex., spring; in e. U.S. and s. Can. (This var. confined from n. Ga. to Ind., Ill., Ia., Kan. and Tex.).

In the Midwest the enormously enlarged burl-like "rootstocks" are known as "grubs." Before the pioneers could cultivate the land the grubs had to be laboriously "grubbed" out; they were too tough for the plows then in use. In colonial times the dried leaves were used as a substitute for tea.

4. *Ceanothus herbaceus* Raf. REDROOT. Much like *C. americanus* but nearly glabrous; leaves narrower, elliptic-oblong and usually not pointed; peduncles terminal and shorter. Incl. var. *pubescens* (T. & G.) Shinners, *C. ovatus* Desf. Mostly well-drained clays and loams in prairies or open brush, or in crevices of limestone bluffs, n.-cen. and s.-cen. Tex., the Panhandle and Edwards Plateau; s. Can. and e. U.S. This species, like *C. americanus*, produces large grubs near the ground surface.

3. ADOLPHIA MEISN. JUNCO

The genus consists of two species that are confined to North America.

1. *Adolphia infesta* (H.B.K.) Meisn. Low nearly glabrous much-branched shrub with greenish thorn-tipped branchlets; leaves opposite or nearly so, small, entire, linear-lanceolate, deciduous; flowers solitary or fasciculate at the axils, the pedicels often white, slender and longer than the cup; cup and disk loosely coherent to the base of the mature ovary, at anthesis often white; sepals 5, white and petaloid, broadly triangular; petals white, sometimes with yellow tips, very small, clasping the anther; fruit dry at maturity, of three 1-seeded carpels that fall from the floral cup and release the seed loculicidally. Arid slopes in the Trans-Pecos, late spring-summer; from Oax. to Tex.

The roots have an anise- or licorice-like odor.

4. RHAMNUS L. BUCKTHORN

Unarmed shrubs or small trees; leaves alternate, unlobed, often with some serrulation on the margin, usually glabrous or nearly so; cup and disk small, quite free from the ovary; sepals 5, small, not colored; petals small, wrapped around the filament; flowers perfect or in 2 of our species unisexual, either solitary in the axils or in axillary pedunculate cymes far-surpassed by the leaves; fruit (when immature) appearing dry and 2- or 3-celled, upon maturity becoming black and juicy and containing 2 or 3 seedlike stonelets that become free from each other but remain in the indehiscent drupe.

Nearly 100 species in temperate and tropical regions. The powerful cathartic, *cascara sagrada*, is obtained from some species of *Rhamnus*.

1. Leaves 15-30 (-40) mm. long, 2 to 2.5 times as long as broad; fruit about 5 mm. long; flowers solitary in the axils; shrub of Trans-Pecos mountains 1. *R. Smithii* subsp. *fasciculata*.
1. Leaves mostly more than 50 mm. long, commonly much longer; fruit commonly at least 5 mm. long; shrubs or small trees (2)
- 2(1). Flowers (or some of them) unisexual, appearing in spring before the leaves or with them, solitary in the axils of the lowest nodes of the emerging vernal innovations; leaves elliptic, 5-7 cm. long, 2 to 3 times as long as broad, with a terminal acuminate apiculation 3-5 mm. long, thin, with inconspicuous (not raised) venation beneath 2. *R. lanceolata*.
2. Flowers perfect, appearing in the late spring with or after the leaves, in axillary pedunculate several-flowered cymes; leaves membranous but not thin, rarely apiculate, with fairly conspicuous usually yellowish and slightly raised venation beneath (3)
- 3(2). Leaves 1.3 to 1.7 (to 2) times as long as broad, with considerable soft pubescence beneath, velvety or felty to the touch 3. *R. betulaeifolia*.
3. Leaves 1.7 to 2.5 times as long as broad, the undersurfaces nearly glabrous or somewhat pubescent but not velvety or felty 4. *R. caroliniana*.

1. *Rhamnus Smithii* Greene subsp. *fasciculata* (Greene) C. B. Wolf. Shrub 1-2 m. tall; leaves numerous, elliptic, 1.5-3 (-4) cm. long; flowers solitary or few fascicled in the axils on short pedicels, some or all of them unisexual. *R. fasciculata* Greene. Arid slopes in Trans-Pecos mts., July-Aug. The species, with several infraspecific members, occurs from Hgo. to Colo. The present subsp. is nearly confined to Texas.

2. *Rhamnus lanceolata* Pursh. Large shrub or small tree; leaves lanceolate-elliptic, 4-7 cm. long; flowers axillary, solitary, at the lowest nodes of the emerging vernal innovation, the concomitant vernal leaves only about 1 cm. long, some of the flowers unisexual. Bottomland hardwood forests in e. Tex., spring; from Pa. to Wisc., s. to Ala. and Tex.

3. *Rhamnus betulaeifolia* Greene. Large shrub or small tree; leaves ovate to obovate, 6-9 (-12) cm. long; flowers in small pedunculate axillary inflorescences. *R. californica* Eschs. var. *betulaeifolia* (Greene) Trel., *R. Purshiana* DC. var. *betulaeifolia* (Greene) Cory, *Frangula betulaeifolia* (Greene) Grub. Moist canyons in Trans-Pecos mts., late spring-early summer; from s.e. Ariz. and N.M. to Coah.

Extremely similar to, and probably conspecific with, the next species.

4. *Rhamnus caroliniana* Walt. INDIAN-CHERRY, YELLOW-WOOD, POLECAT TREE. Large shrub or small tree to 6 m. tall; leaves narrowly ovate to narrowly obovate, 7-14 cm. long. *Frangula caroliniana* (Walt.) Gray. Bottomlands in e. and s.e. Tex., w. near streams into n.-cen. and s.-cen. Tex. and Edwards Plateau, late spring-early summer; from Va. to Neb., s. to Fla. and Tex.

5. BERCHEMIA DC.

SUPPLE-JACK. RATTAN-VINE

About 20 species occur in southeastern Asia and 2 in Africa and Madagascar; another in North America.

1. *Berchemia scandens* (Hill) K. Koch. Glabrous unarmed woody climber and liane; leaves alternate, ovate, 3-6 (-8) cm. long, with numerous conspicuous parallel lateral or secondary veins beneath; cup and disk very small and completely free from the ovary; flowers in small panicles at the ends of lateral branches, mostly overtopped or equaled by the foliage; sepals and petals 5, inconspicuous; fruit when mature juicy, ellipsoidal, about 8 mm. long, with 2-celled and 1- or 2-seeded stone. Forests and forest-edges, e., s.e., n.-cen. and s.-cen. Tex., w. to ravines in s. portion of Edwards Plateau, spring; from Va. to Mo., and s. to Fla. and Tex.; also Chis. and Guat.

6. SAGERETIA BRONGN.

More than 30 species have been proposed, mostly from China; 2 occur in North America and 1 from Mexico to Andean South America, the rest in the warmer parts of the Old World but not in Australia or Africa.

1. *Sageretia Wrightii* Wats. Low shrub; leaves opposite or subopposite, small, shiny; flowers nearly sessile, in ample terminal panicles overtopping the foliage; cup small, quite free from the ovary; sepals and petals 5, inconspicuous; fruit at maturity juicy, black, containing 3 one-seeded stonelets, not dehiscent. Arid slopes in the Trans-Pecos, July-Aug.; from s. Ariz. and Chih. to Coah. and Tex.

7. ZIZIPHUS MILL.

Usually armed and nearly glabrous shrubs or small trees; leaves alternate, usually approaching an ovate or oblong shape, petioled; flowers in axillary cymes; cup nearly filled with a massive disk thickened around but not adherent to the ovary; petals present, falling early; ovary 2-celled, usually biovulate; drupe with a solitary woody 2-celled stone.

The name is often incorrectly spelled "Zizyphus." About 150 species in the warmer parts of the Old World and New World.

- 1. When plants armed the spines axillary, much shorter than the leaves and hooked or curved, the branches never thorn-tipped1. *Z. Jujuba*.
- 1. Plants armed with rather straight stout thorn-tipped branches
.....2. *Z. obtusifolia*.

1. *Ziziphus Jujuba* Mill. JUJUBE. Leaves glossy, usually 2-5 cm. long, usually with 2 small unequally hooked stipular (?) spines at each node (at least on some branches); branches usually zigzag. Infrequent in n.-cen. Tex., rare in e. and s.e. Tex. and in Edwards Plateau and Rio Grande Plains, summer; nat. of the warmer, drier parts of the Old World, widely cult. and now widely escaped and naturalized.

The flesh of the fruits is edible. It is used fresh, dried or preserved, and is useful in cooking and candymaking.

2. *Ziziphus obtusifolia* (T.&G.) Gray. LOTE BUSH, GUMDROP TREE, CLEPE. Branches often covered with a grayish or whitish waxlike bloom, usually terminating in stout thorn-tips; leaves often grayish-green, very variable in shape from deltoid to ovate or oblong to nearly linear, when deltoid or ovate then usually serrate in the upper half. *Z. lycioides* Gray. Locally abundant in much of Tex. except in the e. and the higher parts of the Plains Country, summer; from Okla., Tex., N.M. and Ariz., s. to S.L.P. and Ver.

Our plants pertain to the var. *obtusifolia*. The var. *canescens* (Gray) M. C. Johnst. occurs in Ariz., Nev., Calif., Son. and Baja Calif. The thorn-tipped branches give a superficial resemblance to *Condalia Hookeri* and other *Condalia* species, but the latter are easily distinguished by the bright-green, entire leaves that are broadest in the distal extremity and the branches not whitish.

8. CONDALIA Cav.

Shrubs or small trees, most of the branches ending in stout thorns; leaves alternate, often fascicled on short spur-shoots in which the internodes are suppressed; petioles very short or absent; blades bright-green to sordid-green, either linear or usually obovate or spatulate, entire; flowers solitary or seemingly fascicled at the short shoots; disk seemingly absent or forming a slight annular thickening near the rim of the cup; petals absent except in *C. ericoides*; ovary completely 2-celled at least early in its development, each cell with an ovule, often one of the cells and one of the ovules suppressed early in development and not evident at maturity; fruit a roundish, small drupe.

A genus of 18 species in warm temperate and tropical arid America.

1. Leaves sessile, linear, with no obvious venation pattern; petals present 5. *C. ericoides*.
1. Leaves often short-petiolate, not linear; petals absent (2)
 - 2(1). Leaves very small, spatulate, 4-12 (-14) mm. long, (0.5-) 1.6-3 (-5) mm. broad, the veins slightly prominent and broad and occupying at least 30 per cent of the undersurface of the leaf (3)
 2. Leaves larger, obovate to elliptic, most of them more than 5 mm. long and 3 mm. broad, with inconspicuous venation beneath occupying much less than 30 per cent of the surface (4)
 - 3(2). Leaves (and young branches) entirely glabrous, intervein surfaces beneath with rounded transverse ridges, the undersurface appearing as if molded in wax 4. *C. spathulata*.
 3. Leaves hispidulous, intervein surfaces merely microvesiculate, undersurface not appearing waxy 3. *C. Warnockii*.
 - 4(2). Leaves apically commonly weakly acute, less commonly rounded, 5-8 (-18) mm. long, 2.3-4 (-10) mm. broad 2. *C. viridis*.
 4. Leaves usually rounded apically, rarely slightly acute, (10-) 15-20 (-31) mm. long, (5-) 9-12 (-19) mm. broad 1. *C. Hookeri*.

1. *Condalia Hookeri* M. C. Johnst. BRASIL, CAPUL NEGRO. Leaves obovate, (10-) 15-20 (-31) mm. long, (5-) 9-12 (-19) mm. broad, broadest about a third the distance from the apex, apically mucronate and usually rounded or sometimes truncate and emarginate or rarely slightly acute (minimum angle about 100°), basally acuminate, entire or very rarely with 2 to 4 inconspicuous small introrse teeth in the distal half, membranous, above rather smooth and flavescent buffy-green or occasionally flavescent brownish-green, glabrous or occasionally hispidulous, beneath paler flavescent olive-green with inconspicuous flush venation including the midrib and 3 or 4 pairs of lateral veins; fruit globose, 5-6 mm. thick. *C. obovata* Hook., an illegit. name. Locally abundant, Rio Grande

Plains and margins of adj. regions, n. to Val Verde, Edwards, Kerr, Travis, Austin and Matagorda cos., rare above 2,000 ft. elev., summer; Tam., N.L. and Tex.

There are 2 varieties, the common and widespread var. *Hookeri*, not occurring above 2,000 ft. elev., with blades 1 to 2.5 times as long as broad, and the endemic var. *edwardsiana* (Cory) M. C. Johnst., with blades 2.5 to 3 times as long as broad, known only from one thicket in Edwards Co., at an elevation slightly above 2,000 ft.

2. *Condalia viridis* I. M. Johnst. Leaves elliptic-obovate, 5-8 (-19) mm. long, 2.3-4 (-10) mm. broad, broadest a third to two fifths the length from the apex, apically rounded and apiculate or truncate and emarginate or usually acute (minimum angle about 85°), basally cuneate, marginally entire and very minutely hispidulous at least basally or glabrous, firm, above yellowish-green or grayish-green and microvesiculate and sparsely and very minutely hispidulous or glabrous, beneath usually slightly more flavescent or even glaucous and vesicular and sparsely and very minutely hispidulous or glabrous and with inconspicuous concolorous flush or very slightly raised pinnate venation including the midrib and 3 or 4 pairs of lateral veins; fruit black and globose or even slightly oblate when mature, 5-6 mm. thick. *C. viridis* var. *Reedii* Cory. Locally abundant in dry limy uplands, Edwards Plateau and Trans-Pecos, s.e. to Kinney and Uvalde cos., summer; also Coah., N.L. and S.L.P.

3. *Condalia Warnockii* M. C. Johnst. Leaves usually in fascicles of 2 to 5 at the short shoots, spatulate, 3-7 (-10) mm. long, 1-2.6 (-5) mm. broad, broadest about a third the length from the apex, apically usually acute (minimum angle about 85°), basally acuminate, marginally entire and hispidulous, firm above and sordid-yellowish or brownish-olive or grayish-green and hispidulous, beneath dark olive-green or sordid gray-green and hispidulous with somewhat paler raised venation including the midvein and 2 to 4 pairs of flat-topped or sulcate lateral veins, the venation altogether occupying 30 to 70 percent of the surface; fruit when mature nearly globose, black to reddish-black, 4-6 mm. long, 3-4.5 mm. thick when dry, larger when moist. Locally abundant in deserts in the Trans-Pecos, infrequent e. to w. part of Edwards Plateau and s. part of Plains Country, summer.

Our plants are referable to the var. *Warnockii*, which occurs in Tex., N.M., Chih., Coah. and Zac. The var. *Kearneyana* M. C. Johnst. occurs in Ariz. and Son.

4. *Condalia spathulata* Gray. SQUAW-BUSH. Rounded shrub usually less than 1 m. tall; leaves mostly in fascicles of 2 to 7 at short shoots, entire, spatulate, 4-12 (-14) mm. long, 1.6-3 mm. broad, broadest about a fourth to a third the length from the apex, apically mostly rounded or less commonly emarginate or acute (minimum angle 90°), basally acuminate, marginally slightly thickened and often a little revolute when dry, firm, above grayish-olive to tawny or brownish-grayish-olive, entirely glabrous and often wrinkled when dry, beneath slightly paler and entirely glabrous and with slightly raised, broad, flattened dark veins that occupy more than 40 per cent of the surface, intervein surfaces beneath with some transverse rounded wrinkles, the whole undersurface appearing as if molded in wax; petioles 1 (-2) mm. long; fruit slightly prolate when dry or immature, or nearly globose when mature, black, 3.5-4 mm. long, 2.9-3.5 mm. thick (larger when moist). Locally abundant in dry open brushy areas, Rio Grande Plains, rare in s. part of Edwards Plateau, summer-fall; also Coah., Tam. and N.L.

5. *Condalia ericoides* (Gray) M. C. Johnst. JAVELINA BUSH, TECOMBLATE. Shrub 3-10 (-13) dm. tall; leaves mostly in fascicles of 2 to 9 at short shoots, essentially sessile, linear, 2-13 mm. long, about 1 mm. broad, apically shortly acute, marginally entire, coriaceous, grayish with a waxy texture, above rounded or with a slight median sulcus, beneath with a flat median portion (midvein) occupying most of the width along which are grooves as if the vestigial lateral portions of the blade were revolute, no venation visible; petals shorter than the sepals, spatulate, emarginate, yellowish, membranous, reflexed, caducous; fruit pronouncedly prolate, 7-12 mm. long, 1.5 to 2 times as long as thick, when unripe or abortive dry and yellowish-brown, when fully mature and juicy reddish-black or purplish-black with a thin pulp and a very thick-walled apiculate stone. *Microrhamnus ericoides* Gray. Locally abundant, Trans-Pecos deserts, infrequent in the Plains Country, rare e. to w. part of Edwards Plateau, spring-summer; Ariz., N.M., Tex., Chih., Coah., S.L.P. and Zac.

9. KARWINSKIA Zucc.

One of the 12 species occurs in Texas, the rest in the West Indies, Mexico and Central America, one reaching northern Colombia.

1. *Karwinskia Humboldtiana* (R. & S.) Zucc. COYOTILLO. Unarmed usually glabrous shrub 1-2 m. tall, rarely more; leaves opposite, short-petiolate, usually 3-7 (-8) cm. long, oblong or elliptic-oblong, rounded or acute at both ends, entire, rarely gently crenate, with numerous close and elegantly parallel secondary veins, often each vein beneath with an alternating pattern of lighter and darker coloration; flowers in few-flowered axillary cymes; disk thin; petals present; ovary 2- to 4-celled; fruit a globose drupe, black when ripe. Frequent in Rio Grande Plains, n. to s. part of s.e. Tex. and Edwards Plateau, and extreme s.e. part of Trans-Pecos, summer-fall; Baja Calif., Son., Chih., Tex., Tam., N.L., Coah., S.L.P., Ver., Qro., Gto., Hgo., Jal., Mex., Gro., Pue. and Oax.

The flesh of the fruit is insipid-sweet and edible, but the stones are reported to contain a substance toxic to the nervous system of vertebrates.

FAM. 113. VITACEAE JUSS.

GRAPE FAMILY

Shrubs or woody vines with watery acid juice, usually climbing by tendrils opposite the leaves or on the peduncles; leaves alternate, essentially entire to palmately 3- or 5-lobed or compound; stipules deciduous; inflorescences opposite the leaves; flowers often unisexual and perfect on the same plant, small, regular, greenish, 4- or 5-merous, with a minute or truncated calyx (its limb mostly obsolete) and stamens as many as the valvate petals and opposite them; filaments slender; anthers introrse; style short or none; stigma slightly 2-lobed; grape 2-celled, 1- to 4-seeded; seeds bony, with a minute embryo at the base of the hard albumen.

More than 600 species in about 20 genera widespread in tropical and temperate regions.

1. Bark loosening and freely exfoliating in shreds and without lenticels (excepting in *V. rotundifolia*); pith brownish; leaves simple; inflorescence a compound thyrse; petals separating only at base, falling without expanding; seeds mostly pyriform1. *Vitis*, p. 1015.
1. Bark tight, covered with lenticels; pith white; leaves rarely simple; inflorescence a dichotomous or umbelliform cyme; petals expanding, free from one another, dropping singly; seeds trigonous (2)
- 2(1). Leaves (at least some of them) digitate; some or all tendrils with adhesive disks; ovary adnate to the obscure disk2. *Parthenocissus*, p. 1021.
2. Leaves pinnately compound or sometimes simple; tendrils all with slender tips; ovary surrounded by a free nectariferous or glanduliferous disk (3)
- 3(2). Cyme dichotomous; flowers 5-merous; disk with entire or crenulate margins3. *Ampelopsis*, p. 1022.
3. Cyme umbelliform; flowers 4-merous; disk deeply 4-lobed4. *Cissus*, p. 1022.

I. VITIS L.¹²⁴

GRAPE

Deciduous rarely evergreen polygamo-dioecious viny shrubs, climbing by tendrils; pith brown, interrupted at the nodes by a diaphragm (except in *V. rotundifolia*); leaves simple, dentate, mostly rounded and cordate, usually lobed, rarely palmately compound; flowers fragrant, 5-merous, in a compound thyrse opposite a leaf; sepals minute or obsolete; petals cohering at the apex and falling as a whole at anthesis; disk hypogynous, consisting of 5 nectariferous glands alternate with the stamens; ovary 2-celled; cells

¹²⁴ Ref.: L. H. Bailey in *Gent. Herb.* 3:149-244; T. V. Munson, *Foundations of American Grape Culture.* 1909; W. H. Duncan in *Sida* 3:1-76. 1967.

2-ovuled; style conical, short; fruit a pulpy 2- to 4-seeded berry; seeds usually pyriform, with a contracted beaklike base, with 2 grooves on the ventral side.

About 60 species in the Northern Hemisphere, mainly in temperate regions.

1. Lower surface of fully grown leaves more or less covered with a permanent indument or (if somewhat naked) either whitened to silvery-bluish-green, covered with long cobwebby hairs continuous or in patches (floccose) lying parallel to the surface or with a close continuous felt of hairs completely hiding the surface; younger shoots, petioles and peduncles thinly to densely woolly or pubescent (2)
1. Lower surface of fully grown leaves (except usually the veins) green and glabrous or rarely with short straight hairs erect-spreading from surface; younger shoots, petioles and peduncles glabrous or thinly woolly or with short erect-spreading hairs (6)
- 2(1). Lower surface of leaves with a close continuous felt of white to cream-color hairs that are matted so as to completely and permanently conceal the surface 1. *V. mustangensis*.
2. Lower surface of leaves visible through the indument, with long cobwebby hairs that are either close and forming a continuous covering or commonly occurring in patches of tufts or (if essentially glabrous) the surface whitish or bluish-green, sometimes with some intermixed short straight hairs (3)
- 3(2). Leaves with coarse uneven acute or acuminate teeth that are usually longer than wide, the pubescence gray or whitish; distribution in the Panhandle and Trans-Pecos, east to the northwestern part of north-central Texas 2. *V. acerifolia*.
3. Leaves with shallow acute or rounded and abruptly pointed teeth that are usually about as wide as long or wider, the pubescence yellowish to rust-color or sometimes grayish; distribution east of the Panhandle and Trans-Pecos (4)
- 4(3). Leaves of flowering shoots unlobed or shallowly lobed with the lobes toothed to the base; lower surface of leaves dull-green with a more or less uniform continuous (though often thin) covering of grayish cobwebby hairs 3. *V. cinerea*.
4. Leaves of flowering shoots shallowly or deeply lobed, the deeply lobed ones with entire sinuses; lower surface of leaves usually with grayish or reddish-brown cobwebby hairs, sometimes blue-glaucous and thinly hairy (5)
- 5(4). Lower leaves on flowering branchlets obtuse to acute; axis of inflorescence with brownish or grayish crisped hairs; mound-forming shrubby vines or low-climbers 4. *V. Lincecumii*.
5. Lower leaves on flowering branchlets acute to acuminate; axis of inflorescence with whitish or stramineous (sometimes ferruginous) cobwebby hairs; low- to high-climbing vines 5. *V. aestivalis*.
- 6(1). Tendrils simple, not forked; bark tight, not shredding; pith continuous through the nodes; confined to forests of east Texas 6. *V. rotundifolia*.
6. Tendrils on vegetative parts forked; bark loosening and shredding; pith interrupted at the nodes by cross partitions (7)
- 7(6). Leaves (at least some) deeply lobed (8)
7. Leaves entire or (at most) shallowly lobed (9)
- 8(7). Axis of inflorescence sparsely and loosely long-pubescent or glabrous; fruit gray-bluish and glaucous; margins of leaves often ciliolate . 7. *V. riparia*.
8. Axis of inflorescence densely short-pubescent; fruit black, not glaucous; margins of leaves scarcely or not at all ciliolate 8. *V. palmata*.
- 9(7). Distribution in mountains of Trans-Pecos Texas ... 9. *V. arizonica*.
9. Distribution east of Trans-Pecos Texas or *V. acerifolia* very rare in Presidio County (10)

- 10(9). Leaves with coarse uneven acute or acuminate teeth that are usually longer than wide; distribution almost solely in the Panhandle (an isolated locality in Tierra Vieja Mts.), rare east to the northwestern part of north-central Texas 2. *V. acerifolia*.
- 10. Leaves with shallow acute or rounded and often abruptly pointed teeth that are usually about as wide as long or wider; distribution south of the Panhandle (11)
- 11(10). Leaves rarely more than 8 cm. long; inflorescences rarely more than 6 cm. long; tendrils absent or only opposite uppermost leaves or at tips of flowering or fruiting branches (12)
- 11. Leaves rarely less than 8 cm. long; inflorescences usually much more than 6 cm. long; tendrils present and often on peduncles (13)
- 12(11). Leaves typically reniform and wider than long, commonly conduplicate; a viny shrub or low vine10. *V. rupestris*.
- 12. Leaves typically broadly ovate to triangular-ovate, mostly about as long as wide, not conduplicate; vine climbing over trees and shrubs ..11. *V. monticola*.
- 13(11). Petioles and veins (especially in axils) on lower surface of leaves either with short erect-spreading hairs or glabrous; distribution in eastern third of Texas 12. *V. vulpina*.
- 13. Petioles and veins on lower surface of leaves with cobwebby or flocculent hairs, rarely with some short erect-spreading hairs intermixed, sometimes glabrescent (14)
- 14(13). Endemic to Edwards Plateau; leaves developing fully along with growth of new branchlets13. *V. Berlandieri*.
- 14. In extreme northern part of north-central Texas; rapidly produced new growth of branchlets slender-elongate with very immature leaves 14. *V. cordifolia*.

1. *Vitis mustangensis* Buckl. **MUSTANG GRAPE**. Vigorous high-climbing vine; young growth white-tomentose; diaphragm 3-5 mm. thick; leaves broadly triangular-ovate to ovate-reniform, subacute to obtuse at apex, 6-14 cm. long from top of petiole, about as wide as or wider than long, the basal sinus broad and open to subtruncate at base of leaves, sinuately and shallowly toothed, essentially entire to indistinctly lobed or angled, on vigorous shoots deeply 3- or 5-lobed, white-tomentose on both sides when young, later dark-green and glabrous or somewhat floccose on upper side and permanently white-tomentose (felty) on lower surface; petiole 3-6 cm. long, white-woolly; thyse 5-12 cm. long, the short peduncle and axis woolly and floccose; grape 1.5-2 cm. thick, purple-black to light-colored, without bloom, persistent, with tough skin and of a fiery disagreeable taste; seeds 6-7 mm. long and about as thick. *V. candicans* Engelm. and var. *diversa* Bailey. Along stream bottoms, thickets, fencerows, edge of woods and sandy slopes, especially in disturbed grounds in the e. half of Tex., fruiting Aug.-Sept.; from Tex. to La., Okla. and Ark.

The fruit of some populations is very pungent or fiery in flavor, especially if the skin is chewed, and it is irritating to the mouth and even to the hands. It is frequently used in the making of domestic wine. Fruits of the var. *diversa* (Bailey) Shinnery are very sweet and agreeable.

2. *Vitis acerifolia* Raf. **PANHANDLE GRAPE, BUSH GRAPE**. Stocky erect much-branched short-jointed vines, rarely climbing but often covering rocks and shrubs, early-fruited; younger parts short and leafy, pubescent or tomentose and floccose, whitish or grayish; bark shredding tardily; diaphragm 1-3 mm. thick; tendrils short; stipules conspicuous but shedding early, 5-7 mm. long; leaves light-grayish-green, thick-textured to subcoriaceous, suborbicular to broadly triangular-ovate, abruptly acute to long-acuminate at apex, 7-12 cm. long above the petiole and often broader than long, the basal sinus almost closed to very broad, irregularly and very sharply and coarsely toothed, indistinctly or shallowly lobed or often only shouldered, with age becoming free of cobwebby hairs and tomentum above but usually retaining some cobwebby pubescence especially along the

veins on the lower surface, variously pubescent beneath until midseason or later; petiole short, pubescent or becoming glabrous; thyrses 3-7 cm. long, almost simple, the rachis and very short peduncle at first floccose but becoming glabrous; grapes 8-12 mm. thick, black with a heavy bloom, persisting, with a thin skin, becoming sweet at maturity; seeds 5-6 mm. long, 4-5 mm. broad, rather abruptly short-beaked. *V. Doaniana* Munson, *V. Longii* Price and var. *microsperma* Munson. In low open woods in stream bottoms, and on dunes and rocky slopes in Tex. Panhandle, s.e. to n.w. part of n.-cen. Tex., with an apparently isolated locality in Tierra Vieja Mts., Presidio Co., fruiting July-Aug.; from Tex., n. to Kan. and Colo.

3. *Vitis cinerea* Engelm. GRAYBARK GRAPE, SWEET GRAPE, PARRA SILVESTRE. Lax high-climbing vine; growing tips and branchlets angled, permanently close-pubescent with ashy-white or gray hairs; diaphragm 3-5 mm. thick; stipules 2-4 mm. long; leaves of fertile branches suborbicular to broadly ovate, with a prolonged and tapering triangular apex, 1-2 dm. long above petiole, slightly less wide, the basal sinus either narrow or broad, with irregular usually smallish and shallow apiculate or short-mucronate teeth, either unlobed or with short shoulders or (more rarely) with 2 or 4 prolonged lobes, the upper surface floccose but becoming glabrate, the pale-green or somewhat glaucous lower surface canescent-pilose or grayish-floccose with cobwebby hairs, the looser hairs somewhat deciduous; petiole shorter than the blade, canescent or floccose; thyrses slender, 6-15 cm. long, canescent or gray-floccose, rather open; grapes 4-9 mm. in diameter, blackish or purplish, with a slight bloom, finally sweet; seeds 4-5 mm. long. River and creek banks, bottomlands and pond margins in n.-cen. and e. Tex., fruiting Sept.-Nov.; from Fla. to Tex., n. to Va., O., Ind., Ill., Ia. and Neb.

Those plants with suborbicular-cordate very shallowly toothed leaves that lack the triangular or 3-lobed aspect of var. *cinerea* and whose lower surface is prominently soft-pubescent or densely canescent instead of being cobwebby and/or floccose are referred to var. *canescens* Bailey.

4. *Vitis Linceumii* Buckl. POST OAK GRAPE. Stout moderately climbing vine on low trees but making bushy clumps when standing alone; young shoots densely whitish or light-brownish tomentose, the old wood eventually becoming glabrous; tendrils often twice-forked; diaphragm 2-3 mm. thick; leaves of fertile branches quadrate-rotund to broadly cordate-ovate, thick-textured, 8-15 cm. long from top of petiole and usually or at least frequently broader than long, with a broad basal sinus, coarsely and shallowly toothed, sometimes continuous in outline with obscure shoulders but more often shallowly 3-lobed and frequently deeply 3- or 5-lobed with open rounded smooth sinuses, densely floccose- or webby-tomentose and rarely glaucous on lower surface; petioles tomentose; thyrses 8-15 cm. long, shorter than the leaves, commonly forked, the short peduncle and rachis more or less tomentose or woolly; grapes 1-2 cm. in diameter, black or dark-purple, with a thin bloom, falling at maturity, variable in quality and taste; seeds 7-8 mm. long, 5-6 mm. broad. Incl. var. *glauca* Munson, (?) *V. aestivalis* var. *argentifolia* (Munson) Fern. In sandy open woods, thickets and glades in e. and s.-cen. Tex., w. to Bastrop Co., fruiting June-Sept.; from Miss. to Tex., n. to Ind. and Mo.

5. *Vitis aestivalis* Michx. SUMMER GRAPE, PIGEON GRAPE. High-climbing vine; young branchlets and petioles with rusty or reddish persistent to flocculent-deciduous tomentum or velutinous pilosity; diaphragm 3-4 mm. thick; leaves of fertile branches suborbicular-ovate, cordate, 7-20 cm. long from top of petiole, about as broad as long, the basal sinus mostly deep and prominent, the margins irregularly and not deeply sinuate-toothed and the teeth often sharp, unlobed or merely shouldered to deeply 3- or 5-lobed, upper surface dull-green and essentially glabrous, lower surface with subsistent but loose and flocculent tomentum of cobwebby hairs, the prominent ribs and veins tomentose to velutinous-hispid; thyrses 5-18 cm. long, the axis with cobwebby hairs; grapes 5-12 mm. in diameter, dark-purple or blackish, with a thin bloom, persistent, variable in quality and taste, sometimes sweet and pleasant-tasting; seeds 5-7 mm. long, 4-5 mm. broad. In sandy soils mostly along rivers and streams in the e. third of Tex., fruiting Sept.-Oct.; from Ga. to Tex., n. to Mass., N.Y., O., Mich. and Wisc.

6. *Vitis rotundifolia* Michx. MUSCADINE, BULLACE-GRAPE, SCUPPERNONG. Great vigorous vines, climbing to 30 m. or more over trees and shrubs; bark tight, nonshredding, abundantly dotted with small lenticels; pith continuous through the nodes; tendrils simple,

unbranched; stipules 1-2 mm. long; leaves orbicular to deltoid-ovate, obtuse to acute at apex, the sinus broadly open or the base of leaf nearly truncate, 5-12 cm. long above the petiole, about as wide as long, glabrous but usually somewhat hairy-tufted in axils of veins on lower surface, lustrous, with broad blunt teeth, rarely slightly lobed; petiole slender and about equaling the blade, usually retaining slight pubescence or floccosity; thyse 2-4 cm. long; grapes promptly falling, 12-25 mm. in diameter, purple-black to bronze, without bloom, the skin tough, the flesh musky; seeds oblong, 7-8 mm. long, 4-5 mm. thick. *Muscadinia rotundifolia* (Michx.) Small. Frequent in forests of e. Tex., fruiting Sept.-Oct.; from Fla. to Tex., n. to Del., Va., W.Va., Ind., Mo. and Okla.

The fruits of this species make excellent jelly. Included here is the famous Scuppernong of the Atlantic Coast, with silvery amber-green grapes.

7. *Vitis riparia* Michx. RIVERBANK GRAPE, FROST GRAPE. Vigorous high-climbing vine; new branchlets green or dull-red, glabrous or pubescent and glabrate; diaphragm 0.8-2 mm. thick; leaves of fertile branches with glabrous petioles, 8-18 cm. long from petiole, about as broad as long, cordate-ovate, with a prolonged acuminate apex, with a broad open basal sinus, the margins with coarse acuminate teeth and usually conspicuously ciliate, glabrous or glabrate, with 2 or more erect and prolonged lobes 1-4 cm. long; leaves of vegetative sprouts similar or more deeply palmate-lobed; thyse 4-15 cm. long, its axis and branches sparsely and loosely long-pubescent to glabrous or essentially so; grapes crowded, 8-12 mm. in diameter, purple-black, with heavy bloom, acid; seeds about 5 mm. long. *V. vulpina* of auth. On trees and cliffs in open woodlands, along streams and in canyons in the Trans-Pecos, e. to n.-cen. Tex., fruiting Aug.-Oct.; from Que. to Man. and Mont., s. to Tenn., Mo., Tex. and N.M.

8. *Vitis palmata* Vahl. MISSOURI GRAPE, RED GRAPE, CATBIRD GRAPE. Slender high-climbing vine; shoots and flowering branchlets herbaceous, angled, bright-red when fresh; diaphragm 4-5 mm. thick; stipules 3-4 mm. long; tendrils red when young; leaves of fertile branches thin, ovate, long-acuminate, 7-12 cm. long above petiole, about as broad as long, with a broad open sinus to almost truncate at base of leaf, with little or no cilia on the margins, unevenly large-toothed with sharp or mucronate points, with 2 prolonged acuminate erect lateral lobes; leaves of vegetative shoots larger and with 3 or 5 long-acuminate lobes with broad rounded sinuses; upper leaf surfaces shining dark-green and glabrous except on veins, the lower surface pale and usually retaining pubescence on veins with tufts in the axils; petioles red; thyse 5-15 cm. long, long-stalked, rather open, its rachis and branches copiously hirtellous; grapes 5-10 mm. in diameter, black or bluish-black, without bloom, the skin thick, finally sweet; seeds 4.5-6 mm. long. On margins of ponds or sloughs, or in low woods in e. Tex., fruiting Sept.-Oct.; from La. and Tex., n. to Ind., Ill. and Ia.

9. *Vitis arizonica* Engelm. CANYON GRAPE, GULCH GRAPE, PARRA DEL MONTE. Grayish more or less shrubby vine, mostly small and weak, much-branched, usually not high-climbing; young parts ashy-gray from a tomentum to essentially glabrous; diaphragm 2-4 mm. thick; stipules 2-3 mm. long; tendrils soon deciduous if not attached; leaves broadly cordate-ovate to nearly reniform, with a triangular apex, 5-12 cm. long above the petiole and mostly slightly broader than long, the basal sinus from narrowly inverted U-shaped to broad and open, the margins with rather small or rarely large sharp and mucronate uneven teeth, commonly obscurely lobed or shouldered, rarely deeply 3-lobed, at first both sides cottony, with age the upper surface becoming indifferently floccose and the lower surface more or less permanently covered with grayish-white short erect hairs, the lower surface also commonly becoming glabrous and somewhat glossy except for a usual tuft of erect hairs in the vein axils; petioles often pink-tinged and either slightly floccose or glabrous; thyse 5-10 cm. long, slender-stalked, the short peduncle and rachis more or less floccose to subglabrous; grapes 6-10 mm. thick, black and sometimes with a thin bloom, the skin thin, the pulp juicy and sweet; seeds 4-6 mm. long, 3-4 mm. broad, short-beaked. Climbing on trees, shrubs and over boulders in canyons of mts. in the Trans-Pecos, fruiting Aug.-Oct.; from Tex. to Ariz. and n. Mex.

The leaves of var. *arizonica* are usually smaller and their lower surface is more or less permanently covered with short straight whitish hairs, whereas the var. *glabra* Munson (*V. Treleasei* Munson) has leaves to 12 cm. long and their lower surface is essentially glabrous or the vein axils are provided with small tufts of short straight hairs.

10. *Vitis rupestris* Scheele. SAND GRAPE, SUGAR GRAPE. Low bushy plant to about 25 dm. high or less, with early fruit, seldom climbing, either ascending or prostrate, sometimes trailing over rocks and bushes, bark tardily shredding, young shoots leafy to the tip; diaphragm 2-3 mm. thick; tendrils red, wanting or only at tips of fertile branches; stipules 4-5 mm. long; leaves thick, reniform to reniform-ovate, mostly abruptly short-pointed at apex, the blade folded upward (conduplicate) to form a trough so that the light-colored lower surface is exposed, 5-10 cm. long above the petiole and usually considerably broader, sometimes as much as 2 dm. wide, the base with a broad open sinus to nearly truncate, the margins with few coarse apiculate teeth and often shallowly lobed, glabrous and somewhat shiny on both surfaces, often tinted light-glaucous above; petiole short, angled, glabrous; ground shoots sometimes bearing slightly lobed leaves; thyrses 2-5 cm. long, on a peduncle of equal or less length; rachis and peduncle usually somewhat floccose at anthesis; grapes globose to depressed, 6-12 mm. in diameter, black and somewhat glaucous, soon dropping, the skin thin, pulp sweet and pleasant; seeds 4-5 mm. long and nearly as broad, abruptly short-beaked. On rocky limestone slopes and stream beds on the Edwards Plateau, fruiting July-Sept.; from Tex. and Okla., n. to Mo., W.Va. and Tenn.

11. *Vitis monticola* Buckl. SWEET MOUNTAIN GRAPE. Rather slender small-leaved climber, to about 10 m. high; young growth gray- or white-tomentose or floccose but becoming glabrous, the canes eventually terete; diaphragm 2-3 mm. thick; stipules 3-4 mm. long; leaves suborbicular-reniform to cordate-ovate or deltoid-ovate, obtuse to short-acuminate at apex, 5-10 cm. long above petiole and usually about as broad as long, the basal sinus from almost oblique-truncate to commonly inverted U-shaped, marginal teeth broad-angled and mostly short and ending in a sharp or bluntish mucro or apex, occasionally slightly lobed on the shoulders, eventually becoming glabrous and glossy though a little cotton may remain on the veins of the lower surface; thyrses 4-7 cm. long, forked, compact, the rachis and short peduncle glabrous or only slightly floccose; grapes 6-12 mm. in diameter, black or rarely red or pinkish, roughish, thinly glaucous, sweet; seeds 5-7 mm. long and about as broad, mostly with a short abrupt beak. *V. texana* Munson, ? *V. Champinii* Planch. On limestone hills and ridges of the Edwards Plateau, fruiting Sept.-Oct.; endemic.

The small glossy leaves with squared notches resemble the east Texas *V. rotundifolia*. The more prolonged leaf apices, the branched, not simple, tendrils and shredding, not tight lenticellate, bark, as well as a diaphragm at the nodes, readily separate this species from *V. rotundifolia*.

12. *Vitis vulpina* L. FOX GRAPE, WINTER GRAPE, FROST GRAPE, CHICKEN GRAPE. Vigorous high-climbing vine with stout trunk; young growth glabrous or soon glabrate, the branchlets terete; diaphragm 2-6 mm. thick; stipules 5-8 mm. long; leaves of fertile branches thick-herbaceous, broadly cordate-ovate, usually with a long sharp apex, 8-18 cm. long from petiole, longer than wide, the basal sinus prevalingly broadly inverted U-shaped, coarsely and sharply irregularly toothed, unlobed or merely with angled shoulders, upper surface bright-green and lustrous, lower surface lighter-green and usually glabrous except for short straight hairs on veins and as tufts in the axils of veins; petiole shorter than blade, usually with short straight erect or spreading hairs; thyrses loose and open, to 2 dm. long; fruiting pedicels about 5 mm. long; peduncles sometimes with an early-deciduous tendril; grapes black and shining, often glaucous, 5-10 mm. in diameter, persistent, edible after frost; seeds 5-6 mm. long, 4-5 mm. thick. Edge of woods and in woods, fields, along roadsides and on trees along rivers and streams in e. third of Tex., fruiting Oct.-Nov.; from Fla. to Tex., n. to N.J., Wisc. and Neb.

13. *Vitis Berlandieri* Planch. SPANISH GRAPE, WINTER GRAPE, UVA CIMARRONA. Stocky or stout vine, moderately climbing or in moist favorable situations reaching tops of trees to 12 m. or more high; young growth striate or angled, the tips gray-cottony or -tomentose; diaphragm 3-4 mm. thick; stipules 3-4 mm. long; leaves suborbicular-cordate to cordate-ovate, abruptly acute to short-acuminate at the deltoid apex, 8-12 cm. long above the petiole, commonly broader than long, marginal teeth of different sizes and commonly broad or bluntish although short-apiculate, with short lobes or indications of them toward apex, the basal sinus narrow or broad, upper surface at first with thin cobwebby hairs but soon becoming glabrous and shining dark-green, lower surface somewhat cottony

when young but eventually glossy although retaining cobwebby or somewhat floccose pubescence on ribs and nerves; petioles somewhat shorter than blades, cottony pubescent or floccose; thyse 7-20 cm. long, the stout peduncle and rachis cottony, often strongly forked; grapes 4-8 mm. thick, purple to black or reddish, with light or heavy bloom, pleasant tasting, on pedicels 4-5 mm. long; seeds variable, the largest about 5 mm. long and 4 mm. broad, with a short abrupt beak. *V. Helleri* (Bailey) Small. Climbing on shrubs and trees and over boulders in canyons and on limestone slopes on the Edwards Plateau, fruiting Aug.-Oct.; also adj. Mex.

Those plants that have more rounded leaves with very glossy lower surface and have been designated *V. Helleri* are referred here. On the Edwards Plateau this species is somewhat a counterpart of the more eastern *V. vulpina*.

14. *Vitis cordifolia* Michx. FROST GRAPE, CHICKEN GRAPE. Tall and vigorous vine reaching the tops of the tallest trees and the large trunks to about 8 cm. in diameter; tips slender and rapid-growing, nearly smooth or grayish- to tawny-pubescent but soon becoming glabrous; diaphragm 2-6 mm. thick; stipules 3-5 mm. long; leaves cordate-ovate or sometimes more or less triangular in shape, the apex usually long-pointed and sharp, basal sinus mostly broad, 5-15 cm. long or more above the petiole and about two thirds as wide, the margins variously simply but not deeply apiculate-toothed, mostly unlobed but frequently shouldered or angled and sometimes with a distinct lobe on either side, the upper surface glabrous and glossy, the lower surface light-green and glabrous with tufts in vein axils and usually with some cobwebby hairs along the veins, varying to puberulent and then mostly glabrescent to occasionally distinctly pubescent; petioles slender, sometimes nearly as long as the blade, with cobwebby or flocculose hairs; thyse slender and open, 6-15 cm. long, frequently forked at or near base, the peduncle slender but short, the fruiting pedicels about 5 mm. long; grapes 3-10 mm. in diameter, black and only slightly if at all glaucous, persistent, sweet after frost; seeds about 5 mm. long, 3-4 mm. broad. In thickets and open woods in n.-cen. Tex., fruiting Oct.-Nov.; from Tex. and Okla. to Fla., n. to Pa. and Kan.

2. PARTHENOCISSUS PLANCH. VIRGINIA CREEPER. WOODBINE

Woody vines, trailing or climbing by branched tendrils that affix themselves by twining tips or by enlarged terminal adhesive disks; leaves digitate or palmately lobed; leaflets 3 to 7, rather coarsely serrate; inflorescence cymosely compound; flowers perfect or unisexual; calyx slightly 5-toothed; petals free, concave, thick, expanding before they fall; disk none; berries with thin flesh; seeds 1 to 4.

About 10 species in North America and eastern Asia.

- 1. Leaflets fleshy-thickened, mostly 7, 3-5 cm. long, to about 2 cm. wide; endemic to the Edwards Plateau1. *P. heptaphylla*.
- 1. Leaflets thin-herbaceous, usually 5 or 6, typically much more than 5 cm. long and 2 cm. wide (2)
- 2(1). Tendrils with 3 to 8 branches that terminate in adhesive disks; leaves dull on upper surface; inflorescence with a pronounced central axis; in the eastern half of Texas2. *P. quinquefolia*.
- 2. Tendrils with 3 to 5 diskless branches; leaves glossy on upper surface; inflorescence dichotomously forked; in west Texas3. *P. vitacea*.

1. *Parthenocissus heptaphylla* (Buckl.) Small. Vine, sometimes climbing to 10 m., glabrous, with long forking tendrils; leaflets mostly 7 but occasionally 5 or 6, sessile or short-petiololed, oblanceolate to oblong-oblanceolate or sometimes the lateral oblong-lanceolate, acuminate, fleshy-thickened, 3-5 cm. long, to about 2 cm. wide above the middle, coarsely few-toothed above the middle or somewhat incised, glossy on upper surface, often cuneately narrowed at base; corymbs 4-8 cm. broad, pendulous; berries subglobose, to 1 cm. in diameter, dark-blue to nearly blackish, glaucous; seeds as many as 4, to 6 mm. long. *Ampelopsis heptaphylla* Buckl., *Parthenocissus texana* Rehd., *Psedera texana* (Rehd.) Greene. Climbing over small trees and shrubs in rocky or sandy soils, endemic on the Edwards Plateau.

Besides their smallness, the leaves of this species are quite fleshy-thickened, resembling somewhat those of *Cissus* in texture.

2. *Parthenocissus quinquefolia* (L.) Planch. VIRGINIA CREEPER, HIEDRA, PARRA. High-climbing vine by means of adhesive disks of the 3 to 8 tendril branches; leaflets distinctly petiolulate, to about 15 cm. long and 5 cm. wide, oblong-obovate to elliptic, acuminate, coarsely toothed, pale-green and dull above, glaucescent beneath, glabrous or pubescent in f. *hirsuta* (Donn) Fern. [*P. hirsuta* (Donn) Small]; cymes usually approximate and with a prolonged central axis, forming a paniculate inflorescence with a solitary ascending to divergent lower branch and as many as 200 or more flowers; berries 5-7 mm. in diameter; seeds 1 to 3. In woods and on rocky banks, in open woodlands, on fences and edge of forests in the e. half of Tex., May-July; from Fla. to Tex., n. to N.E., Ind., Ill. and Minn.

3. *Parthenocissus vitacea* (Knerr) Hitchc. THICKET CREEPER. Plant loosely climbing or trailing; tendrils with 3 to 5 slender-tipped twining branches without disks; leaves lustrous above, green and glabrous to thinly pubescent beneath; leaflets mostly 5-12 cm. long; inflorescences mostly scattered in elongate panicles or solitary, without a prolonged central axis, consisting of a pair of subequal divergent few-flowered branches; berries 8-10 mm. long; seeds 3 or 4. *P. inserta* (Kern.) Fritsch. In woods, thickets and on banks in w. Tex., May-July; from Que. to Man. and Mont., s.w. to Wyo. and Tex.

3. AMPELOPSIS MICHX.

Climbing or erect shrubs with tight bark and lenticels, the pith white, with or without tendrils opposite the leaves; leaves thin, deciduous; inflorescence a dichotomous cyme; flowers small, greenish, mostly 5-merous and perfect; calyx scarious, saucer-shaped; petals free, spreading; disk cup-shaped, free from ovary except at base, the margins entire or scarcely crenate; berry dry or pulpy; seeds 1 to several, trigonous-obovoid.

About 25 species in North America and Asia.

1. Leaves simple or rarely only shallowly lobed, cordate to truncate at base 1. *A. cordata*.
 1. Leaves twice-pinnate or ternate, the leaflets small 2. *A. arborea*.

1. *Ampelopsis cordata* Michx. Plant nearly glabrous, high-climbing; leaves petiolate, broadly ovate to suborbicular-ovate, cordate to truncate at base, acuminate at apex, to about 15 cm. long and wide, typically smaller, coarsely and sharply toothed, unlobed or very rarely with some shallowly 3-lobed, dark-green above, pale-green beneath; paniculate cymes lax; style slender; berries oblate, less than 1 cm. in diameter, bluish-purple or greenish. *Cissus Ampelopsis* Pers. In rich woodlands and bottomlands along rivers and streams in the e. half and the Panhandle of Tex., Apr.-June; from Fla. to Tex. and Mex., n. to Va., O., Ind., Ill. and Neb.

2. *Ampelopsis arborea* (L.) Koehne. PEPPER-VINE. Plant nearly glabrous, bushy or high-climbing; leaves petiolate, triangular-ovate in outline, twice-pinnate or ternate, 15 cm. long or more; leaflets ovate to rhombic-ovate, acute to acuminate at apex, rounded to cuneate at base, the larger ones 3-7 cm. long, coarsely cut-toothed, dark-green above, pale-green beneath; cymes rather short, mostly less than 8 cm. long; disk very thick, adherent to the ovary; berries black, pulpy, subglobose to obovoid, 1-1.5 cm. in diameter. *Cissus arborea* (L.) Des Moul. Along streams, in and on edge of swamp forests, in fencerows and waste places, mostly in s. and e. Tex., June-Aug.; from Fla. to Tex. and n.e. Mex., n. to Md., Ill., Mo. and Okla.

The Mexican *A. mexicana* Rose has been reported as being in southwest Texas where it might occur as an escape from cultivation. No material from Texas has been seen. Its distinctive 3-foliolate leaves readily separate it from our two indigenous species.

4. CISSUS L. POSSUM-GRAPE

A mostly pantropical genus with several hundred species.

1. *Cissus incisa* (Nutt.) Des Moul. MARINE-IVY IVY TREEBINE, COW-ITCH, HERBA DEL BUEY. A stout heavy vine with warty tight-barked stems to at least 10 m. long from

tuberous roots; pith white; leaves petiolate, fleshy-thickened and succulent, to 8 cm. long and about as wide, deciduous or semievergreen, extremely variable, from simple and broadly ovate or ovate-reniform to more or less trilobed or trifoliolate, the margins coarsely and irregularly toothed; leaflets ovate to obovate, cuneate; peduncle at first usually exceeding the subtending leaf, supporting an umbelliform cyme; flowers 4-merous, perfect or unisexual; petals free, spreading; disk a deeply 4-lobed cup that is free from the ovary except at its base; berry obovoid, black, 6-8 mm. long, dry, beaked by the persistent style, on recurved pedicels, 1- to 4-seeded; seeds trigonous-obovoid. Sprawling or climbing over rocks, trees and shrubs in chaparral, salt marshes and open woodlands, throughout most of the state, rare or absent in the extreme e. part and in the Panhandle, May-Sept.; from Fla. to Tex. and adj. Mex., n. to Mo. and Kan.

Plants with simple undivided leaves are frequent in the Rio Grande Plains and Valley. There seems to be no other difference, however, that would separate these plants from the typical plants with trilobed or trifoliolate leaves.

The tropical American *C. sicyoides* L. (WATERWITHE TREEBINE or BEJUCO LOCO) has been reported as being in southwest Texas. Although the species is known from Tamaulipas State, Mexico, no material has been seen from Texas. It is easily distinguished by its entire, ovate-cordate succulent leaves whose margins are finely bristle-toothed.

FAM. 114. TILIACEAE JUSS. LINDEN FAMILY

Trees or shrubs, the pubescence mainly of stellate or branched hairs; leaves alternate or rarely opposite, simple or sometimes lobate, usually serrate, stipulate; flowers usually perfect, regular, solitary or in cymes or panicles; sepals 5 or rarely 3 or 4, free or coherent, deciduous, commonly valvate; petals as many as the sepals, mostly imbricated in the bud; stamens usually numerous and indefinite in number, distinct or mostly united into 5 or 10 bundles, some often staminodes; anthers 2-celled; fruit 2- to 10-celled or (by abortion) 1-celled, dry or drupaceous, dehiscent or indehiscent.

About 450 species in 50 or more genera, mostly tropical and subtropical.

- 1. Trees; peduncle adnate to a bract; fruit nutlike, globose, indehiscent 1. *Tilia*, p. 1023.
- 1. Shrubs or herbaceous; peduncle free, not adnate to a bract; fruit capsular, linear-oblong, dehiscent 2. *Corchorus*, p. 1024.

1. TILIA L. BASSWOOD. LINDEN

Trees with soft white wood and fibrous tough inner bark, the pubescence of simple or stellate hairs; leaves petiolate, the broad blade very oblique at base and palmately veined, serrate; stipules deciduous; flowers fragrant, white or yellowish, 5-merous, in axillary cymes; peduncle adnate about to the middle of a narrow short-petioled foliaceous membranous bract; sepals distinct; petals spatulate-oblong; stamens numerous, distinct or united into 5 bundles each of which is in front of a petal; staminodes lacking or present with one in front of each petal; fruit globose, nutlike, tomentose, dry and woody, indehiscent, 1- or 2-seeded.

A genus of about 50 polymorphic species mainly of Asia with a few in eastern North America and Mexico.

In regard to *Tilia*, the recent tendency of some workers is to consider the basswoods of southern United States as one extremely polymorphic species; namely, *T. americana* L. Other researchers tend to recognize as many as 16 species in this part of the country. Any present treatment must be tentative and, consequently, unsatisfactory. It is, of course, less frustrating to "lump" all of the basswoods into one polyglot species.

- 1. Expanding and mature leaves glabrous or sparsely pubescent with simple hairs; peduncles and pedicels glabrous 1. *T. americana*.
- 1. Expanding leaves stellate-pubescent; mature leaves stellate-tomentose or glabrescent with stellate and simple hairs (2)

- 2(1). Mature leaves somewhat rusty-brown stellate-tomentose to sparsely stellate-pubescent; peduncles and pedicels glabrous or glabrescent 2. *T. caroliniana*.
2. Mature leaves glabrous or glabrescent with stellate and simple hairs; peduncles and pedicels pubescent 3. *T. floridana*.

1. *Tilia americana* L. AMERICAN BASSWOOD. Tree to 40 m. high; branchlets green, glabrous; leaves with a glabrous petiole 3-5 cm. long, broadly ovate, obliquely cordate to truncate at base, abruptly acuminate at apex, to 2 dm. long, coarsely serrate with long-pointed teeth, glabrous from the first, light-green beneath, commonly with tufts of hairs in the axils of the lateral veins; flowers about 15 mm. across, in pendulous 6- to 15-flowered slender-branched cymes, with staminodia; pedicels glabrous; inflorescence bract usually stalked, glabrous, tapering toward the base; stamens shorter than the petals; fruit ellipsoid to subglobose, thick-shelled, without ribs. In rich moist soils of woods and bottomlands in n.e. Tex., spring-summer; from Can., s. to Va. and Ala., w. to N.D., Kan. and Tex.

2. *Tilia caroliniana* Mill. CAROLINA BASSWOOD. Large tree to about 30 m. high; leaves with stout glabrous to slightly pubescent petioles to 35 mm. long, broadly ovate, obliquely truncate to cordate at base, abruptly acuminate at apex, to 13 cm. long, with coarsely dentate margins, the upper surface dark-green, clothed with rusty-brown woolly hairs on the lower surface; cymes 8- to 15-flowered; inflorescence bracts essentially glabrous; fruit subglobose to ellipsoid, pubescent, about 6 mm. in diameter. *T. phanera* Sarg. In open woodlands, along forested streams and lowlands in e. and cen. Tex., spring-summer; from N.C., s. to cen. Fla., w. to s.w. Ark. and Tex.

3. *Tilia floridana* Small. FLORIDA BASSWOOD. Tree to 20 m. or more high, with furrowed bark; twigs yellowish to reddish-brown; leaves thin, broadly ovate to ovate-oval, obliquely truncate to subcordate at base, abruptly short-acuminate at apex, to 12 cm. long, coarsely serrate with conspicuously gland-tipped teeth, deep-green above, white-villous to white-tomentose and often glaucous beneath (especially when young), soon glabrate; inflorescence bracts relatively small, spatulate or scythe-shaped, 10-15 cm. long, mostly much less than 2 cm. wide, somewhat rounded at base and decurrent to within 5-15 mm. of the base of the peduncle, somewhat pubescent; cymes few-flowered; peduncle pubescent, the free portion 5-15 mm. long; pedicels pubescent; sepals lanceolate to linear-lanceolate, 3-3.5 mm. long; petals about 5 mm. long; staminodia nearly linear to linear-spatulate, slightly shorter than the petals; fruit globular. *T. nuda* Sarg., *T. leucocarpa* Ashe. In rich woods in e. and cen. Tex., Apr.-June; from Fla. to Tex., n. to s.e. Va., s. Ind., s. Ill. and Mo.; also n.e. Mex.

2. CORCHORUS L.

About 100 species in warm regions of the world. The fiber, jute, is obtained from two Old World species.

1. *Corchorus hirtus* L. ORINOCO JUTE, MORALIA. Plant herbaceous or subshrubby, usually much less than 1 m. high, minutely pubescent to glabrate throughout, the stems simple or sparingly branched; leaves alternate, with short pilosulous petioles, ovate to oblong-elliptic or narrowly lanceolate, subobtuse to acuminate, serrate, to 6 cm. long; flowers solitary or in clusters of 2 or 3 opposite the leaves; pedicels to 5 mm. long; sepals and petals 5 or rarely 4; sepals linear-lanceolate, acuminate, to 8 mm. long; petals obovate to linear-spatulate, a little shorter than the sepals; stamens 10 (in ours); filaments filiform, simple; anthers introrse; capsule slender, siliquelike, to 6 cm. long, 4-celled, ascending or spreading, flattened contrary to the septum, appressed-puberulent, short-beaked, longitudinally dehiscent. Incl. var. *orinocensis* (H.B.K.) K. Schum. *C. orinocensis* H.B.K. In waste places and along roadsides in s. Tex., throughout year; from Fla. to Tex. and Ariz., s. through Latin Am.

FAM. 115. MALVACEAE JUSS.¹²⁵

MALLOW FAMILY

Plants herbaceous or shrubby, rarely arborescent, with more or less mucilaginous sap, usually pubescent with simple, stellate or forked hairs; leaves simple, alternate, petioled, stipulate; flowers regular, perfect; calyx often subtended by a calyxlike involucre; petals 5, hypogynous, convolute in the bud, asymmetric, more or less united at base to the stamen column; stamens numerous, monadelphous; anthers 1-celled, reniform; pollen grains large, spiny; carpels 3 or more, 1-celled; style usually several-branched; fruit a loculicidal capsule or (in most of the genera) the mature carpels separating from one another and from the receptacle; seeds often pubescent.

About 1,000 species in about 75 genera in tropical and temperate regions throughout the world. A family of highly ornamental plants, with numerous species of *Hibiscus*, *Malva*, *Abutilon* and *Althaea* under cultivation. It includes the cotton plants (*Gossypium* spp.), the vegetable okra (*Hibiscus esculentus* L.) and the marsh-mallow (*Althaea officinalis* L.), of Europe, whose mucilaginous root is used in making the popular confection.

1. Style branches and stigmas twice the number of the carpels; stamen tube not filamentiferous at the apex, this usually dentate; stigmas capitate or discoid; fruit a schizocarp; carpels normally 5, often indehiscent or tardily dehiscent; ovule solitary, ascending (2)
1. Style branches and stigmas of the same number as the carpels or the style unbranched and the stigmas entire or nearly so (4)
- 2(1). Petals auriculate on one side of the claw; fruit berrylike until fully mature, with a fleshy outer envelope; plants shrubby or arborescent; flowers solitary in the axils or in terminal or subterminal clusters; involucre of 5 to 16 narrow bractlets; corolla funnelform, the petals connivent or spreading only at apex; column usually long-exserted; carpels indehiscent, unappendaged, becoming dry and stony, usually finally separating1. *Malvaviscus*, p. 1028.
2. Petals not auriculate; fruit not berrylike or fleshy (3)
- 3(2). Inflorescence subtended by an involucre of conspicuously veined foliaceous bracts, these often whitish and scarious toward base; flowers often attached to the bracts; involucre none and the inner flowers subtended only by narrow stipules; plants herbaceous2. *Malachra*, p. 1029.
3. Inflorescence not foliaceous-involucrate or the bracts wholly foliaceous; flowers free from the subtending bracts; involucels always present, the bractlets various; plants shrubby or suffrutescent3. *Pavonia*, p. 1029.
- 4(1). Fruit capsular or baccate, the carpels remaining attached to one another and to the axis; stamen tube usually not filamentiferous at the apex, usually dentate or lobed; involucre usually present but sometimes much-reduced; fruit loculicidally dehiscent or indehiscent, the cells 5 or fewer (5)
4. Fruit usually a schizocarp, the carpels separating finally from one another and from the axis; stamen tube filamentiferous at and often also below the apex (8)
- 5(4). Style branches becoming more or less divergent, the stigmas more or less capitate or discoid; seeds usually reniform (6)
5. Style branches short and erect or the style unbranched and clavate; seeds usually angulate or obovoid (7)
- 6(5). Ovules solitary, ascending; capsule depressed, saliently 5-angled; involucre of 5 to 10 narrow bractlets, rarely obsolete; plants herbaceous or somewhat shrubby4. *Kosteletzkya*, p. 1029.
6. Ovules 2 or more in each cell; capsule not depressed or (if lightly so) not saliently angled5. *Hibiscus*, p. 1029.

¹²⁵ Parts of this treatment adapted from various publications of T. H. Kearney; generic key adapted from Am. Midl. Nat. 46:93-131. 1951.

- 7(5). Plants herbaceous or suffrutescent; bractlets of the involucl more than 3, small and narrow, or the involucl wanting; calyx deeply 5-cleft, the oil glands (when present) in definite longitudinal rows; cotyledons not black-dotted 6. *Cienfuegosia*, p. 1033.
7. Plants with a somewhat ligneous stem; bractlets 3, persistent and foliaceous to small, subulate and caducous; calyx dentate to nearly entire, with oil glands usually scattered but sometimes in rather definite longitudinal rows; cotyledons black-dotted 7. *Gossypium*, p. 1033.
- 8(4). Stigmas decurrent on the style branches, the latter filiform to clavate but usually not noticeably expanded at the very apex (9)
8. Stigmas apical or very nearly so, capitate to discoid or obliquely truncate, usually distinctly larger than the apices of the style branches (12)
- 9(8). Bractlets of the involucl distinct, 1 to 3 or sometimes wanting; herbs with lobed or parted leaves (10)
9. Bractlets more or less united; herbs or shrubs (11)
- 10(9). Carpels usually with an inflexed or incurved beak, this often with its cavity partly separated from the larger seed-containing cavity by an endoglossum (transverse projection from the dorsal wall); petals broadly truncate, usually erose or fimbriate at apex; taproot often much-thickened 8. *Callirhoe*, p. 1033.
10. Carpels beakless, the cavity not divided; petals often deeply notched; taproot not thickened 9. *Malva*, p. 1035.
- 11(9). Involucl with 6 or more (rarely only 5) lobes; receptacle (columella) not enlarged at apex or projecting above the carpels; plants herbaceous 10. *Althaea*, p. 1036.
11. Involucl with 3 to 6 lobes; receptacle enlarged (conical or discoid) at apex, often projecting above the tip of the carpels; plants herbaceous to shrubby or arborescent 11. *Lavatera*, p. 1037.
- 12(8). Ovules normally 2 or more in each carpel (13)
12. Ovules normally solitary in each carpel (18)
- 13(12). Involucl none (14)
13. Involucl present (17)
- 14(13). Carpels more or less completely divided into 2 superposed cavities; herbs or shrubs (15)
14. Carpels 1-celled, the cavity undivided (16)
- 15(14). Carpels 5 (rarely 3, 4 or 6), 2-celled by horizontal or oblique constriction of the lateral walls, with no internal projection from the dorsal wall 12. *Wissadula*, p. 1037.
15. Carpels 5 to 11, 2-celled by a horizontal projection (endoglossum) from the dorsal wall 13. *Pseudabutilon*, p. 1038.
- 16(14). Carpels greatly inflated, rounded and mucicous at apex, the walls thin and papery; plant herbaceous or merely suffrutescent, the stems often weak and vine-like; flowers relatively small, on slender axillary peduncles; carpels promptly loculicidal and tardily septicidal, normally hirsute with long hairs 14. *Herissantia*, p. 1038.
16. Carpels not or only moderately inflated, commonly more or less pointed at apex and mucronate to rostrate or aristate, the walls firm-membranous to coriaceous; plants herbaceous to shrubby or arborescent; flowers often large and showy 15. *Abutilon*, p. 1038.

- 17(13). Carpels almost completely septate by a transverse projection (endoglossum) from the dorsal wall, with 1 ovule in each compartment; stamen tube filamentiferous at apex; plants herbaceous; bractlets 3, more or less persistent, often foliaceous; carpels deeply incised, often bicuspidate or biaristate on the dorsal angle, rugose below, hirsute, septicidal and partly loculicidal . . . 16. *Modiola*, p. 1042.
17. Carpels not septate but the dorsal wall sometimes bearing a palatolike internal fold (endoglossum) at base of the dehiscent section of the carpel, this projecting a short way into the cavity; stamen tube usually filamentiferous below as well as at the apex; nectary of 5 segments; carpels often remaining attached to the axis long after maturity by a threadlike branch of the midrib . . 17. *Sphaeralcea*, p. 1042.
- 18(12). Involucel present; ovule (except in *Sida*) erect or ascending (19)
18. Involucel absent or (rarely in *Sida*) a false involucel of several narrow bracts borne on the peduncle shortly below the calyx (22)
- 19(18). Cavity of the carpel more or less completely divided into 2 compartments by a transverse septum (endoglossum), the lower compartment holding the seed; annual or perennial herbs; bractlets 3, adnate to or borne below the calyx; carpels dehiscent to about the middle . . . 16. *Modiola*, p. 1042.
19. Cavity of the carpel not divided but sometimes (in *Sphaeralcea*) with a palatolike fold (endoglossum) of the dorsal wall at base of the dehiscent section, this projecting a short way into the cavity (20)
- 20(19). Carpels sharply differentiated into a smooth dehiscent empty apical section and a reticulate indehiscent basal section, the latter containing the seed; annual or perennial herbs; bractlets small and narrow, usually caducous . . . 17. *Sphaeralcea*, p. 1042.
20. Carpels not sharply differentiated apically and basally, usually without reticulation (21)
- 21(20). Ovules erect or ascending; plants annual or perennial, herbaceous to shrubby; carpels incurved-rostrate to muticous, usually more or less rugose, sometimes appendaged externally on the back, the lateral walls firm and persistent to thin and soon disintegrating . . . 18. *Malvastrum*, p. 1047.
21. Ovules pendulous; plants perennial, herbaceous; stems decumbent or prostrate; herbage closely stellate-canescens or lepidote; flowers axillary; mostly solitary; involucel present or absent; fruit discoid to hemispheric; carpels muticous or short-beaked, the lateral walls disintegrating and releasing the seed . . . 21. *Sida*, p. 1049.
- 22(18). Fruit technically a capsule, the 5 carpels loculicidal to the base but not or incompletely septicidal and not (or very tardily) separating from the axis at maturity; leaves entire or dentate, cordate; ovule pendulous . . 19. *Bastardia*, p. 1048.
22. Fruit a schizocarp, septicidally dehiscent, the carpels separating from the axis and usually from one another at maturity (23)
- 23(22). Carpels greatly inflated, much larger than the seed, muticous, the walls thin, papery or membranous (24)
23. Carpels not greatly inflated (25)
- 24(23). Carpel cavity not divided and without an internal appendage; ligaments (attaching threads) usually wanting or poorly developed . . 14. *Herissantia*, p. 1038.
24. Cavity usually partly divided longitudinally by an outgrowth (endoglossum) originating near the base of the dorsal wall but becoming detached and often finally appearing as if attached to the ventral wall, the endoglossum often pectinate and more or less embracing the seed; ligaments present, 2 or 3 per carpel, holding the carpel attached to the columella until maturity . . . 20. *Gaya*, p. 1049.

- 25(23). Carpel cavity partially divided into 2 superposed compartments by a transverse fold or ring at base of the dehiscent portion; plants shrubby or suffrutescent; leaves entire or nearly so; carpels 4 or 5, not reticulate basally 12. *Wissadula*, p. 1037.
25. Carpel cavity not divided as above but an endoglossum (palatelike internal projection from the dorsal wall) sometimes present in *Sphaeralcea* (26)
- 26(25). Carpels differentiated into a smooth ventrally dehiscent apical section and a usually larger rugose-reticulate indehiscent basal section; plants herbaceous 17. *Sphaeralcea*, p. 1042.
26. Carpels not differentiated apically and basally (27)
- 27(26). Ovules erect or ascending 18. *Malvastrum*, p. 1047.
27. Ovules pendulous or resupinate-horizontal (28)
- 28(27). Lateral walls of the carpels firm, persistent; seeds without an aril-like envelope; flowers axillary and solitary or more or less aggregated in racemes, spikes or heads; calyx usually angulate, sometimes much-acrescent, the lobes commonly erect or connivent over the fruit; carpels mucous to birostrate or biaristate, often rugose or muricate, indehiscent or slightly dehiscent at apex 21. *Sida*, p. 1049.
28. Lateral walls of the carpels fragile, soon disappearing or becoming lacerate; seeds usually more or less enveloped by an arilliform often reticulate endocarp, this sometimes closely adherent to the seed coat; fruit discoid to nearly hemispheric, depressed, the carpels incurved and with a dorsal angle, umbo or spur 22. *Anoda*, p. 1054.

1. MALVAVISCUS FABR.

Shrubs with many-branched stems; leaves alternate, petiolate, with caducous stipules, toothed, often lobed or angled; flowers usually red, pedunculate, axillary or racemose; involucre bractlets several to numerous; calyx campanulate, 5-lobed; corolla contorted, tubelike; petals 5, erect-connivent or spreading only above, obovate-cuneate, emarginate, auriculate at base; staminal column exerted, 5-parted at apex, bearing numerous stamens toward the apex; fruit 5-celled; carpels baccate, indehiscent, 1-seeded.

A small American genus of about 20 complex species.

1. Leaves suborbicular-ovate, about as broad as long, deeply cordate at base 1. *M. arboreus* var. *Drummondii*.
1. Leaves ovate-lanceolate, much longer than broad, rounded to broadly cuneate at base (2)
- 2(1). Flowers 23-42 mm. long 1. *M. arboreus* var. *mexicanus*.
2. Flowers more than 42 mm. long 1. *M. arboreus* var. *penduliflorus*.

1. *Malvaviscus arboreus* Cav. var. *Drummondii* (T.&G.) Schery. DRUMMOND WAX-MALLOW, TEXAS MALLOW. Shrub to 3 m. high, tomentulose; leaves rounded-cordate, 4-9 cm. long, fully as broad as long, obtuse to acute at apex, usually 3-angulate or shallow 3-lobate, the margins crenate-dentate; bractlets of involucre linear-spatulate; corolla vermilion-red, 2-3.5 cm. long; fruit red, said to be edible either raw or cooked. *M. Drummondii* T. & G. Limestone slopes and ledges, in wooded arroyos, along streams and in palm groves from s. Edwards Plateau southw. and eastw., flowering throughout the year; from Fla. to Tex.; also adj. Mex. and Cuba.

The var. *mexicanus* Schlecht. is rare in the Rio Grande Valley, thence southw. to Col. and the W.I. The var. *penduliflorus* (DC.) Schery (*M. penduliflorus* DC.) is frequently cult. in the Rio Grande Plains and Valley where it occurs as an escape. It occurs naturally from Mex. to n. S.A.

2. MALACHRA L.

About 6 species mostly in the American tropics.

1. *Malachra capitata* L. MALVA DE CABALLO. Erect perennial herb, usually branched, velvety stellate-pubescent and often with some long whitish hairs, to 15 dm. high; leaves long-petioled, broadly ovate to suborbicular, dentate or obtusely 3- or 5-lobed, the lower leaves to 12 cm. long, the upper leaves smaller; stipules subulate, to 15 mm. long; heads several-flowered, mostly on axillary peduncles; outer bracts broadly ovate, concuplicate, cordate at base, acute at apex, strongly nerved against a whitish background, velvety, 2-2.5 cm. long, the smaller inner bracts ovate; flowers perfect; calyx 6-8 mm. long, its 5 lobes ovate-lanceolate and obtuse; petals 5, inequilateral, yellow or orange-color, about 1 cm. long; stamen tube shorter than the petals, 5-toothed, bearing 15 to 30 filaments at about the middle; carpels 5, obtuse, convex, reticulated, nearly glabrous, 2.5-3 mm. long. Fields, thickets, palm groves, roadsides, waste places and cult. grounds in s. Tex., flowering throughout the year; from Tex. to C.A. and the W.I.

3. PAVONIA Cav.

About 200 species, mostly tropical and subtropical.

1. *Pavonia lasiopetala* Scheele. Plant shrubby, to about 15 dm. high, tomentulose and cinereous; leaves alternate, petioled, stipulate, ovate-cordate or subcordate, obtuse to acutish at apex, the margins coarsely serrate or repand, sometimes slightly angulate-lobed, 25-75 mm. long; flowers perfect, solitary on slender peduncles in the axils; bractlets of involucl 5 to 8, linear, rather longer than the 5 ovate acuminate 3- to 5-nerved calyx lobes; petals 5, rose-color, ciliate on the claw, 12-20 mm. long; stamen column not appendaged; styles 10, the stigmas capitate; carpels 5, 1-celled, smooth or obscurely reticulated, when mature separating from axis. *P. Wrightii* Gray. In rocky woods on the Edwards Plateau and Rio Grande Plains, flowering the year around; also adj. Mex.

4. KOSTELETZKYA PRESL SALT MARSH-MALLOW

About 30 species, mostly in tropical America and Africa.

1. *Kosteletzkya virginica* (L.) Gray. Branched perennial herb closely resembling *Hibiscus*, to about 15 dm. high, rather roughly stellate-hirsute or -tomentose throughout, greenish or somewhat cinereous; leaves gray-green, densely pubescent, the lower ones cordate-suborbicular to -ovate and angulate or coarsely toothed, the upper and bracteal leaves mostly lanceolate and without or with hastately divergent basal lobes; pedicels capillary to coarse and short, frequently equaling or exceeding the bracteal leaves; flowering calyx minutely puberulent to densely pubescent, 5-lobed, 8-13 mm. long, its linear-subulate bracteoles 6-10 mm. long; petals 5, roseate, 3-4.5 cm. long, 2-3 cm. wide; column (including styles) 15-25 mm. long; fruit prominently 5-angled, depressed; carpels copiously villous-hirsute with hairs 1.5-2 mm. long; seeds smooth, one in each carpel. In brackish or nearly fresh marshes and along shores and in swamps, along coastal Tex., June-Oct.; from Fla. to Tex., n. to Va. and Del.; also Cuba.

Our plant is usually referred to var. *althaefolia* Chapm. [*K. althaefolia* (Chapm.) Gray], characterized by having its stems and calyces densely pubescent.

5. HIBISCUS L. ROSE-MALLOW

Plants perennial or rarely annual, often shrubby; leaves merely crenate or dentate, or pedately cleft; flowers axillary, solitary, the petals 2 cm. long or more; involucl usually present; fruit a loculicidal capsule, the carpels 5; seeds several in each cell, essentially glabrous to long-hairy.

About 300 species mainly in tropical and subtropical regions.

1. Leaves and stems glabrous (2)

1. Leaves and stems more or less variously pubescent (4)

- 2(1). Deciduous shrub; leaves typically triangular-ovate to rhombic, the lobes (when present) broad; cultivated species 1. *H. syriacus*.
- 2. Herbaceous perennial; leaves typically lanceolate, the lobes (when present) narrow; indigenous species (3)
- 3(2). Bracteoles and calyx densely hirsute 2. *H. dasycalyx*.
- 3. Bracteoles and calyx glabrous or very sparsely hirsute 3. *H. militaris*.
- 4(1). All leaves 3- or 5-parted, the primary segments oblong-cuneate to linear-elliptic (5)
- 4. Leaves entire or lobate, the lobes triangular-ovate to -lanceolate (6)
- 5(4). Plant a low diffuse annual; calyx strongly veined, papery, with short triangular-ovate lobes above the middle; cultivated species ... 4. *H. trionum*.
- 5. Plant a rigidly erect shrubby perennial; calyx not veiny, herbaceous, with narrow lanceolate lobes extending to near base; indigenous in Trans-Pecos Texas 5. *H. Coulteri*.
- 6(4). Small shrubs of dry soils, rarely to 6 dm. high, mostly in central and west Texas; petals to about 3 cm. long (7)
- 6. Large herbaceous perennials of moist or wet places, more than 10 dm. high, mostly in east and north Texas; petals usually much more than 3 cm. long (8)
- 7(6). Bractlets of involucl lanceolate-spatulate, only slightly shorter than the calyx lobes; leaves conspicuously cordate at base; corolla bright-red; seeds sparsely short-hirsute 6. *H. cardiophyllus*.
- 7. Bractlets of involucl short-setaceous to obsolete, mostly less than half as long as the calyx lobes; leaves broadly cuneate to truncate at base; corolla pinkish or lavender; seeds covered by long silky hairs 7. *H. denudatus*.
- 8(6). Stems usually with prickles; calyx lobes long-attenuate at apex; capsules densely covered with long spreading simple tawny hairs ... 8. *H. cubensis*.
- 8. Stems not prickly; calyx lobes mostly acute-apiculate at apex; capsules short stellate-pubescent to glabrous (9)
- 9(8). Leaves commonly elliptic-lanceolate and broadly cuneate to rounded at base, with age usually becoming glabrous above, gray-pannose beneath; capsules glabrous 9. *H. Moscheutos*.
- 9. Leaves ovate to ovate-lanceolate, rounded to cordate at base, permanently pubescent on both surfaces; capsules more or less pubescent (10)
- 10(9). Upper surface of leaves bearing many simple or subsimple hairs; bractlets of involucl ciliate with long simple hairs in addition to being shortly stellate-tomentose; capsules usually densely villous-hirsute ..10. *H. lasiocarpus*.
- 10. Both surfaces of leaves with a very fine and dense stellate pubescence; bractlets without long simple hairs; capsules eventually glabrescent 11. *H. leucophyllus*.

1. *Hibiscus syriacus* L. **ALTHEA, ROSE-OF-SHARON**. Rather large erect branched essentially glabrous shrub, 3-6 m. high; leaves rather small, triangular-ovate to rhombic, 5-7.5 cm. long, strongly 3-ribbed, most of the lower ones 3-lobed, the margins variously toothed or notched; flowers axillary on short peduncles, 5-7.5 cm. across; bracts linear, about the length of the triangular calyx lobes; corolla variously colored from cream-color to white or bluish, often double; fruit oblong-ovoid, about 25 mm. long. A nat. of e. Asia that is commonly cult., but frequently persists about abandoned homesteads and in waste places.

2. *Hibiscus dasycalyx* Blake & Schiller. Herbaceous perennial to 15 dm. high; stem greenish, terete, glabrous, about 3 mm. thick above; upper nodes mostly 3-5 cm. long; leaves with slender petioles 3-5 cm. long, 3-lobed and hastate at base, 5-9 cm. long, 3-10 cm. wide at base across the lobes, glabrous, the lobes linear-attenuate (3-6 mm. wide) and usually irregularly incised or serrate; flowers 6 or 7, solitary in uppermost axils; peduncles about 15 mm. long, articulate near middle, with spreading hairs above; bracteoles about 12, narrowly linear-attenuate, the inner surface and margins densely

hirsute, hirsute to subglabrous on outside, about 15 mm. long, 1-1.5 mm. wide; calyx about 25 mm. long, campanulate, densely spreading-white-hirsute on outside, densely yellowish-pilose with subappressed hairs on inner surface, the lobes deltoid-apiculate and about 7 mm. long; corolla white with a purple spot, when dry about 6 cm. long, the apex spreading; ovary densely and subappressed yellowish-pilose; styles free above and there pilose; fruit unknown. Rare in Trinity Co. in e. Tex., May-July; endemic.

3. *Hibiscus militaris* Cav. SCARLET ROSE-MALLOW, HALBERD-LEAVED ROSE-MALLOW. Herbaceous perennial, often tinged with red; stems to 25 dm. high, essentially glabrous; leaves with slender petioles to 1 dm. long or more, triangular-hastate in general outline, glabrous, the basal lobes (if developed) widely divergent, the middle lobe long-acuminate and 2 to 6 times as long as the body of the leaf; bractlets linear-setaceous, tapering to a filiform point, to 3 cm. long; calyx glabrous or very nearly so; petals obovate, pink or whitish with a purplish base, 6-8 cm. long; capsule glabrous or nearly so; seeds pubescent with short reddish-brown hairs. In marshes and shallow water in e. and n.-cen. Tex., reported from the Panhandle, May-Nov.; from Fla. to Tex., n. in the interior to O. and Minn.

4. *Hibiscus trionum* L. FLOWER-OF-AN-HOUR. Depressed branching hispid to glabrate annual, to 6 dm. high, with some of the branches becoming prostrate; leaves 3-lobed or most of them 3- to 5-parted, the segments mostly cuneate-oblong to spatulate, with the middle segment much the largest, all coarsely toothed or incised; bracts linear; flowers solitary; pedicel elongating in fruit; calyx setose, papery, dark-striped, becoming inflated; corolla sulphur-yellow or whitish, with a brown-purple center, 5-7.5 cm. across, closing in the shadows; seeds muricate-papillose. A nat. of Cen. Afr., now a weed in N.A.; spontaneous in cen. and n. Tex., summer-fall.

5. *Hibiscus Coulteri* Harv. DESERT ROSE-MALLOW. Suffruticose or even shrubby, to 1 m. high, strigosely hirsute with few-rayed stellular hairs; leaves dimorphous, the lower ones broadly ovate to ovate-oval and dentate, the upper ones mostly divided into 3 narrow coarsely dentate lobes, about 25 mm. in diameter, of rounded or ovate outline; lowest leaves commonly undivided, cordate or ovate, incisely serrate and slightly lobed; upper leaves 3-cleft and the lobes ovate or some 3- to 5-parted into narrower serrate lobes, sometimes all 3- to 5-parted; flowers few, long-peduncled; pedicels usually disarticulating at maturity of the fruit; bractlets of the involucl 10 to 14, linear-setaceous, rigid, 2 cm. or less long, about the length of the attenuate-lanceolate 3-nerved lobes of the 5-parted calyx, both sparsely hispid with simple rigid hairs; petals broadly obovate, 2-4 cm. long, whitish to lemon- or sulphur-yellow and commonly reddish- or purple-tinged; capsule glabrous, shorter than the calyx; seeds covered with long hairs. In desert areas, hills and slopes in the Trans-Pecos, Apr.-Aug.; from Tex. to Ariz. and adj. Mex.

Apparent hybrids between this species and *H. denudatus* have been seen in the Eagle Mts., Hudspeth Co.

6. *Hibiscus cardiophyllus* Gray. TULIPÁN DEL MONTE. Herbaceous from a lignescent perennial base, stellately canescent-tomentose throughout; stems 3-6 dm. high, equally leafy to top; leaves with petioles to 7 cm. long, broadly ovate, cordate at base, obtuse at apex, more or less sinuate-dentate to crenate or sometimes angulate, 3-7 cm. long, slightly less wide, pale beneath and densely stellate-tomentose; peduncles surpassing the leaves; involucl of about 10 spatulate-lanceolate 3-nerved tomentose bractlets, rather shorter than the elliptic-lanceolate calyx lobes; petals crimson to deep rose-red, 2.5-3 cm. long; capsule glabrous, about 15 mm. long; seeds rather few, puberulent. In canyons, on talus slopes, gravelly hills, about boulders and breaks, in chaparral in the Rio Grande Plains, on limestone hills n.w. to Val Verde Co., throughout the year; also adj. Mex.

7. *Hibiscus denudatus* Benth. Suffruticose, 3-6 dm. high, stellately canescent-tomentose, with several to numerous rigidly erect or ascending stems; leaves sessile or with petioles to 1 cm. long, ovate to suborbicular or ovate-oblong, rounded to obtuse at apex, broadly cuneate to truncate or slightly cordate at base, to 35 mm. long, coarsely crenate-serrate, finely stellate-pubescent; flowers short-peduncled in the axils and commonly along the somewhat naked flexuous summit of the branches; involucl of 4 to 7 short setaceous bractlets, sometimes obsolete or as much as half the length of the 5 lanceolate acuminate canescent-tomentose calyx lobes; petals lavender-purple, 2-3 cm. long; capsule glabrous or pubescent at apex; seeds few, densely long silky-pubescent. Incl. var. *involucellatus*

Gray. In canyons, crevices, on rocky slopes and clayey hillsides in the Trans-Pecos, Mar.-Oct.; from Tex. to Calif. and adj. Mex.

8. *Hibiscus cubensis* A. Rich. Herbaceous perennial, to 3 m. high, densely gray-velutinous throughout (except on corolla) with short stellate hairs; stem (sometimes also the petioles and peduncles) remotely or rather densely aculeate with straight spreading (at length) corky-based prickles 3 mm. long or less, the prickles apparently sometimes lacking; leaves with petiole 2-6 cm. long, triangular-lanceolate to oblong-lanceolate or ovate-oblong, 8-11 cm. long, 3.5-5 cm. wide, acute to acuminate, subtruncate to shallowly cordate at base, the margin crenate-serrate throughout, not at all or only obscurely greener above than below; peduncles solitary in the upper axils, to 35 mm. long, jointed almost to the base; bractlets about 12, narrowly linear or (in age) somewhat involucremargined and linear-filiform, 12-15 mm. long, to 1.5 mm. wide, sometimes sparsely hispid as well as densely velutinous, in age reflexed; calyx (in flower) about 28 mm. and at maturity about 32 mm. high, sometimes more or less hispid outside (especially on the nerves), the broadly triangular acuminate teeth about equaling the tube; corolla 8-9 cm. long, purplish-pink with dark-reddish basal blotch, the petals with spreading tips; capsule subglobose, abruptly apiculate, densely spreading-hispid outside with ochroleucous hairs and between them minutely hispidulous, glabrous inside; seeds densely and shortly rufescent-velvety 2.5 mm. long; styles united to apex; stigmas oblong. In marshes and along canals in s.e. Tex., May-Oct.; in temp. and trop. Am.

9. *Hibiscus Moscheutos* L. SWAMP ROSE-MALLOW, MALLOW-ROSE. Plants erect, to about 25 dm. high, the stems minutely stellate-pubescent to glabrescent; leaves with slender petioles to about 5 cm. long, ovate to elliptic-lanceolate or lanceolate, canescent-pannose beneath with minute and close down, less so to glabrate and green above, broadly cuneate to rounded or subcordate at base, acuminate at apex, to about 22 cm. long and 9 cm. wide, the margins coarsely incised-dentate, unlobed or with the middle and lower leaves tricuspidate; with one to several peduncles usually fused for as much as three fourths their length to the subtending petiole; bractlets and calyx canescent but not hairy; petals 5-10 cm. long, light creamy-yellow or white with a crimson-purple base; style branches glabrous or remotely hispid; capsule conic-ovoid, tapering to an erect beak, glabrous, 2.5-3 cm. long. *H. incanus* Wendl. In low wet areas on edge of woods, swamps and wet meadows in e. Tex., June-Oct.; from Fla. to Tex., n. to Md., Va., W.Va., O. and Ind.

10. *Hibiscus lasiocarpus* Cav. WOOLLY ROSE-MALLOW. Plants erect, to about 2 m. high, the stems pubescent; leaves with petioles to 1 dm. long, broadly to narrowly ovate, cordate to subcordate at base, acute to acuminate at apex, the margins crenately dentate, occasionally some leaves angulate or somewhat 3-lobed, 1-2 dm. long, more or less velvety-tomentose on both sides with the upper surface bearing many simple or subsimple hairs, the uppermost leaves often ovate-lanceolate; bractlets more or less ciliate with villous or hirsute cover; calyx lobes at maturity prominently 5- or 7-nerved; corolla white or pale rose-color with a crimson or deep-purplish-red blotch at base, the petals 7.5-10 cm. long; capsule short-cylindric, subtruncate, usually densely villous-hirsute. In marshes, floodplains, ditches and along streams and rivers from e. to n.w. Tex., June-Sept.; from Ga. to Tex., n. in the Miss. basin to Ky., Ind., Ill. and Mo.

11. *Hibiscus leucophyllus* Shiller. Roots perennial, succulent; stems to 8 dm. high, somewhat branched upwardly, densely puberulous with minute many-branched sessile stellate hairs; leaves numerous, with petioles to 4 cm. long, densely puberulous like the stems, narrowly ovate, to 14 cm. long and 6 cm. wide, rounded or the larger leaves subcordate at base, sharply long-acuminate at apex, coarsely and bluntly serrate except at very base and at apex, 7-nerved at base, the nerves raised beneath and impressed above, light olive-green above, paler and ashy beneath, densely stellate-pubescent on both sides, the hairs beneath conspicuously whitish; peduncles axillary, one-flowered, shorter than the pedicels; involucre of numerous linear free bractlets that are much shorter than the calyces, densely tomentulose, lacking long simple bristly hairs on the margins; calyx 2-2.5 cm. long, the ovate lobes longer than the tube, densely stellate-tomentulose externally; petals 7-8 cm. long, white with a purple blotch at the base; capsule short-beaked, 2-2.3 cm. long, densely and minutely stellate-tomentose when young, finally glabrescent although with some persistent hairs along the margins of the valves; seeds glabrous. In sandy moist soils in s.e. Tex., May-July; also La. and Miss.

6. CIENFUEGOSIA CAY.

About 20 species of tropical and subtropical regions.

1. *Cienfuegosia Drummondii* (Gray) Lewton. YELLOW FUGOSIA. Perennial somewhat woody herb, essentially glabrous throughout, with dark dots; stems rather stout, rigidly ascending, to about 5 dm. high; leaves with petioles to 3 cm. long, oval, to 6 cm. long, the margins coarsely repand-dentate; stipules caducous; peduncles stout, dilated upward, equaling or exceeding the subtending leaves; flowers perfect, solitary on long peduncles in axils; involucl of 7 to 9 linear or spatulate-oblong bractlets that are little shorter than the deeply 5-cleft calyx; petals 5, convolute, short-clawed, rounded or obcordate, greenish-yellow or sulphur-yellow, about 25 mm. long; stamen tube shorter than the petals; stigmas 4 or 5; capsule globular, glabrous, loculicidally 3- or 4-valved; seed 2 in each cell, tomentulose. *C. sulphurea* (H.B.K.) Hassl. var. *glabra* Gke. In clayey soils in fields and open thickets along the coast and in s. Tex., Feb.-June; also S.A.

7. GOSSYPIUM L. COTTON

Herbs, shrubs or trees in tropical regions, cultivated as an annual in warm-temperate regions, the herbage commonly glandular-dotted and punctate; leaves palmately-ribbed or -lobed; flowers axillary, large; involucre or "square" of 3 to 7 united or separated entire to more or less lacerated bracts; calyx entire or somewhat 5-lobed; petals large, convolute, white, yellow or purple, often changing color after opening; fruit a dehiscing 3- to 5-celled capsule or "boll," each cell containing several fuzzy or smooth seeds whose epidermis produces the lint or "cotton" of commerce.

About 20 species in both hemispheres, several of which are of great economic importance.

1. *Gossypium hirsutum* L. UPLAND COTTON, ALGODÓN. This, our commonly cultivated cotton, is occasionally found as a waif. It is distinguished by its coarsely toothed or serrated involucl bracts and short staminal column with anthers loosely arranged on filaments of varying length.

8. CALLIRHOË NUTT.¹²⁶ POPPY-MALLOW

Plants hirsute or hispid with both simple and branched hairs; leaves palmately parted, the lobes toothed or pinnatifid; flowers large and showy, solitary on long axillary peduncles; without or with an involucl of 3 bractlets; petals cuneate, erose-denticulate at the truncate apex; carpels numerous, deeply reticulate, with a short inflexed beak.

About 7 species in the United States and northern Mexico.

1. Calyx subtended by an involucl of 3 bracts (2)

1. Calyx not subtended by an involucl (6)

2(1). Involucl bracts separated from the calyx, at least one of them usually 1-3 mm. removed; upper leaves with lobes mostly entire (3)

2. Involucl bracts not noticeably separated from the calyx; upper leaves with segments having teeth on secondary lobes (4)

3(2). Backs of carpels yellowish sericeous-pubescent; stem densely rough-pubescent with ascending mostly 8-rayed hairs; fruiting peduncles 4-7 cm. long, about 2 mm. thick; central Texas 1. *C. scabriuscula*.

3. Backs of carpels glabrous; stems slightly pubescent with appressed mostly 4-rayed hairs; peduncles 10-19 cm. long, about 1 mm. thick; east Texas 2. *C. Papaver*.

¹²⁶ Treatment based on U. T. Waterfall in Field & Lab. 19:107-119. 1951.

- 4(2). Sinuses between leaf lobes extending to within 2-4 mm. of the petiole; stipules 20-70 or rarely to 100 mm. long and 1.5-4 or rarely to 5 mm. wide; carpels glabrous or with varying amounts of strigose pubescence 3. *C. involucrata* var. *lineariloba*.
4. Sinuses between leaf lobes extending to within 5-15 mm. of the petiole; stipules 7-15 mm. long and 6-14 mm. wide; carpels strigose (5)
- 5(4). Sinuses extending to within 5-10 mm. of the petiole 3. *C. involucrata* var. *involucrata*.
5. Sinuses extending to within 10-15 mm. of the petiole, the lobes few-toothed 3. *C. involucrata* f. *novomexicana*.
- 6(1). Carpels strigose-pubescent, at least on the beaks; carpel beaks protruding above the body, forming the upper one-third to one-fourth of the compound fruit (as seen from the side) 4. *C. alcaeoides*.
6. Carpels glabrous (7)
- 7(6). Carpel beaks not or only slightly elevated above the body of the mature carpel, scarcely visible above the body of the compound fruit when viewed from the side; back of the mature carpel body not or only slightly prolonged over the base of the beak; plant perennial 5. *C. digitata*.
7. Carpel beaks usually protruding above the body of the mature carpel to form about one-third of the upper part of the fruit; back of the carpel body prolonged about 1 mm. into a conspicuous whitish chartaceous "collar" covering the base of the beak; plant annual 6. *C. leiocarpa*.

1. *Callirhoë scabriuscula* Robins. TEXAS POPPY-MALLOW. Plant annual, erect, to about 45 cm. high, covered throughout with a fine close slightly rough mostly 8-rayed stellate tomentum; leaves suborbicular in outline, to 4 cm. long and 55 mm. wide, deeply and palmately 3- or 5-cleft; leaf lobes oblong to oblanceolate or linear-oblanceolate, entire to few-toothed, obtuse; petioles of the lower leaves 7.5-10 cm. long and channeled above, the upper leaves shortly petioled to subsessile; stipules lance-linear, about 1 cm. long; peduncles rather rigid, much-exceeding the subtending sessile foliaceous 3- or 5-parted bracts; the 3 involucre bracts linear, about 1 cm. long, 1-2 mm. below the calyx; calyx lobes lanceolate, acuminate, 3-nerved, 8-10 mm. long; petals obovate, subtruncate, red or purple, 25 mm. long or more; carpels 14 to 16, to 5 mm. high and 3.5 mm. wide, the backs and exposed side-margins densely pubescent, the sides thin and reticulated. A rare Tex. endemic found along the Colorado River.

2. *Callirhoë Papaver* (Cav.) Gray. Perennial from a long narrow woody root; stems 3-6 dm. long, ascending to decumbent, sparsely appressed-pubescent with mostly 4-rayed hairs, sometimes glabrate, rarely with the lower part of the stem pilose; leaves with petioles equal to or many times longer than the blade, hastate, cordate, triangular or ovate in outline, 3-8 cm. long and 4-9 cm. wide, deeply palmately or pedately 3- or 5-cleft into almost entire (sometimes sinuate-toothed or -lobed) linear-falcate to lance-falcate divisions, the uppermost leaves sometimes reduced to a single lobe; stipules ovate to rhombic-ovate or oblong, to 12 mm. long and 7 mm. wide; peduncles long and slender, commonly 2 or 3 times as long as the subtending leaf; the 3 involucre bracts mostly 1-3 mm. below the calyx, usually linear and about one half as long as the calyx; calyx 1-1.5 cm. long, the united basal portion varying from slightly to densely hispid with simple hairs to 3 mm. long, the lobes lanceolate and their tips somewhat attenuate; petals 25-35 mm. long, red, erose-denticulate at the broad apex; carpels about 20, 4 mm. high, with reticulate sides. In pine-oak flatwoods, on caliche outcrops and grassy banks in e. Tex., Mar.-July; from Fla. to Tex., n. to Ga. and Mo.

3. *Callirhoë involucrata* (Torr.) Gray. Perennial, the stems mostly decumbent from an elongate to napiform root, to about 6 dm. long, hirsute or even hispid; principal cauline leaves 2.5-5 cm. long, 3-6 cm. wide, usually 5- or 7-parted or -cleft to within 5-10 mm. of petiole; leaf segments mostly cuneate at base and variously toothed or incised to

lobed or parted above the central segment, 5-10 mm. wide at base; stipules to 15 mm. long and about as wide, ovate to rhombic-ovate or ovate-lanceolate, cordate; peduncles surpassing the leaves; involucler contiguous with the calyx or very rarely slightly removed, each of the bracts (6-12 mm. long) linear or linear-lanceolate to narrowly ovate-rhombic; calyx 1-2.3 cm. long, divided to near base into mostly lanceolate lobes, sometimes varying to ovate-rhombic with attenuate tips; corolla 4-6 cm. in diameter; petals reddish-purple, cuneate to obovate-cuneate, truncate to somewhat rounded at the slightly fimbriate apex; carpels 16 to 25, strigose. In sandy or gravelly soils in open woods, on rocky hills, in scrubland and thickets, throughout Tex. except in the Trans-Pecos, Feb.-June; from N.D. to Wyo., s. to Mo., Okla., Tex. and Ut.

The variations in this species are denoted in the key. *C. geranioides* Small is referable to var. *lineariloba* (T.&G.) Gray. The f. *novomexicana* (E.G.Baker) Waterfall is very close to var. *involutrata*.

4. *Callirhoë alcaeoides* (Michx.) Gray. PLAINS POPPY-MALLOW. Perennial from an oblong or napiform root; stems several, erect or ascending, to about 45 cm. high, appressed-pubescent with 4-rayed hairs or sometimes glabrate; leaf blades 5-9 cm. long, 4-10 cm. wide, mostly cordate or triangular-cordate; blades of basal leaves crenate or incised to palmately parted, their petioles equal to or twice as long as the blade, the segments mostly lancinate-cleft, the ultimate leaf divisions mostly oblong to linear; petioles of cauline leaves mostly as long as blade, essentially lacking in uppermost leaves; inflorescence corymbose at anthesis, later elongating; peduncles to 8 cm. long; calyx lobes united below middle, lanceolate, sometimes attenuate, about 1 cm. long, the pubescence of short strigose mostly appressed simple hairs; petals 15-22 mm. long, pink or white; carpels 10, strigose-pubescent, 4-5 mm. high. *C. triangulata* of auth. In prairies of n.-cen. Tex., Mar.-May; from Ill. to Neb., s. to Ala., Tenn., Mo., Okla. and Tex.

5. *Callirhoë digitata* Nutt. Plant perennial, erect or reclining, to about 10 dm. high, the stems glabrous and glaucous to pilose-strigose; lower petioles usually 15-25 cm. long, often with a trace of pilose-strigose hairs; leaf blades mostly cordate or ovate, palmately or pedately 5- or 7-parted, with some of the divisions sometimes again parted into segments that are narrowly linear to linear-lanceolate and to 11 cm. long; stipules linear-lanceolate to ovate-lanceolate, to 12 mm. long, persistent or early-deciduous, commonly absent at flowering time; peduncles to 15 cm. long; involucler absent; calyx lobes strongly veined and lanceolate-acuminate; petals 1-2 cm. long, red or purple, the apex irregularly fimbriate; carpels 12 to 14, glabrous, dorsally rugose, 4-5 mm. high. In open woods and on plains, prairies and grassy slopes in cen. and n.-cen. Tex., Mar.-June; from Tex., n. to Ark., Mo. and Kan.

Our plant is usually referred to var. *stipulata* Waterfall with smaller stems and leaves, and larger and nondeciduous stipules than in var. *digitata*. Flowers with white petals are referred to f. *alba* Waterfall.

6. *Callirhoë leiocarpa* Martin. Plant annual, with several slender stems from a slender taproot, erect, to about 85 cm. high, glabrous or slightly pubescent with small 4-rayed hairs; leaves with petioles shorter than to about 3 times as long as the blade, reniform-cordate to ovate in outline, to 6 cm. long and about as wide, crenate to palmately or pedately 3- to 6-parted; leaf segments cuneate or oblong to lanceolate or falcate, to linear, entire to lobed; upper leaves usually more deeply parted and with narrower lobes than the lower ones; peduncles many, in fruit diverging from the upper part of the stem; fruiting calyx 9-15 mm. long and 5-8 mm. wide, united below the middle, the lobes lanceolate to linear-lanceolate and somewhat attenuate; petals to about 23 mm. long, red-purple to light-pink, finely and regularly erose at the broad summit; carpels 10 to 12, glabrous, 4-5 mm. high, smooth to slightly wrinkled dorsally, the beak large and hollow, the back of carpel body prolonged about 1 mm. into a white chartaceous collar that subtends the base of the beak. *C. pedata* Gray. In woods, mesquite groves, prairies and plains in cen. and s. Tex., Mar.-Aug.; also Okla.

9. MALVA L. MALLOW. CHEESE-WEED

Plants annual, biennial or perennial, sparsely pubescent or glabrate; leaves orbicular or reniform; flowers small, axillary, solitary or in small cymules, short-pedicelled,

involucellate; petals white or pink; style branches filiform, introrsely papillate; fruit depressed, disklike, the carpels numerous, compressed, reniform, indehiscent.

An Old World genus of about 40 species. The young leaves of several species, especially *M. parviflora*, when boiled as a potherb, are edible and nutritious.

- 1. Flowers mostly in terminal spikelike racemes, only the lowest ones axillary; petals 15-30 mm. long, 4 to 5 times as long as the sepals, purple-red 1. *M. sylvestris*.
- 1. Flowers axillary; petals 4-12 mm. long, less than 2.5 times as long as the sepals, pale-blue to white (2)
- 2(1). Petals about twice as long as the sepals 2. *M. neglecta*.
- 2. Petals (at most) slightly longer than the sepals (3)
- 3(2). Claw of petals pilose; pedicels 10-25 mm. long; calyx not enlarged in age 3. *M. rotundifolia*.
- 3. Claw of petals not noticeably pilose; pedicels 3-15 mm. long; calyx much-enlarged in age 4. *M. parviflora*.

1. *Malva sylvestris* L. HIGH MALLOW. Perennial with erect stems to about 1 m. high, sparsely hirtellous to glabrate; leaves orbicular to reniform in shape, shallowly 3- to 7-lobed, the lobes broadly rounded, serrate, the basal ones 5-10 cm. in diameter; petioles pubescent only or chiefly in a single line on the upper side; bractlets ovate to oblong or obovate; flowers fascicled in the upper axils, on peduncles to 5 cm. long; petals red-purple, 2-2.5 cm. long; carpels about 10, rugose-reticulate on the back, with angled edges, glabrous to sparsely short-pubescent. Nat. of Euras. that has become an escape in the e. third of Tex., May-Aug.

2. *Malva neglecta* Wallr. COMMON MALLOW. Annual or long-lived herb; stems prostrate, procumbent or ascending, to about 1 m. long, usually branched from the base; leaves long-petioled, orbicular to reniform, 3-6 cm. wide, shallowly 5- to 9-lobed, crenate, cordate to subcordate at base; flowers fascicled in the axils, with pedicels to 3 cm. long; bractlets narrow; petals obcordate, 6-12 mm. long, white or slightly tinged with pink or purple; carpels usually 12 to 15, rounded on the back, not rugose or reticulate, usually finely pubescent, the whole ring of carpels presenting a crenate outline, the depressed central portion of the head about a third as wide as the head. A nat. of Euras. and N. Afr. that has become established in various localities throughout Tex., Apr.-July.

3. *Malva rotundifolia* L. COMMON OR DWARF MALLOW. Similar to *M. neglecta* in habit and foliage; stems procumbent from a large and deep firm root; leaves rounded, slightly 5- to 7-lobed, crenate; pedicels often little longer than the calyx; corolla about 13 mm. long, pale, surpassing the calyx; carpels 8 to 15, glabrous or pubescent, conspicuously rugose-reticulate on the back, the margins sharply angled, the whole head of carpels approximately circular in outline, the central depressed area about one fifth the diameter of the whole head. *M. borealis* Wallr. Nat. of Eur. that is established as a weed in n.-cen. and w. Tex., Apr.-June.

4. *Malva parviflora* L. Plant glabrous or sparsely pubescent, usually with several to many stems erect or ascending from an annual root, to about 2 m. high; leaves with long slender petioles, suborbicular to reniform and often somewhat angulate-lobed, to about 6 cm. long and usually wider than long; pedicels usually short; flowers clustered in the axils, whitish or bluish-white, about 5 cm. across; calyx lobes broadly ovate, in fruit much-enlarged and spreading; petal claws glabrous; carpels puberulent or glabrous, sharply and transversely reticulate-rugose on the back, the margins of which are somewhat wavy-winged and denticulate. In thickets, along roadsides, in waste ground and cult. soils throughout much of Tex., Mar.-July; distributed over much of N.A.

10. ALTHAEA L.

About a dozen species native to the Old World; cultivated in gardens for their showy flowers.

1. *Althaea rosea* Cav. HOLLYHOCK, AMAPOLA GRANDE. Biennial, to 25 dm. high; stems strict, hairy; leaves with long petiole, large and rough to touch, rugose, orbicular in

outline, cordate at base, 5- to 7-lobed or wavy-angled, crenate; flowers essentially sessile, 8 cm. wide or more, variously colored, mostly deep rose-color to pink or lavender, arranged at apex of stem in a long wandlike raceme or spike; bracts 6 to 9 below the calyx, connate at base; very similar to *Malva*. A nat. of Asia that is cult. and is occasionally found as a waif along roadsides and about abandoned homesteads, summer-fall.

11. LAVATERA L. TREE-MALLOW

About 30 species in both hemispheres.

1. *Lavatera trimestris* L. Branching herbaceous annual 9-18 dm. high; leaves long-petiolate, irregularly crenate-dentate, finely pubescent or nearly glabrous, the lower suborbicular-cordate, the upper ones angled; stipules caducous; flowers solitary, axillary, 8-10 cm. across; pedicels jointed below the flowers, mostly shorter than the subtending leaves; the 3- to 6-lobate involucre shorter than the 5-lobed calyx; petals 5, rose-pink or red, obtuse to truncate or emarginate, short-clawed; ovary discoid; carpels 5 to 12, verticillate about a prominent axis, beakless, 1-seeded, indehiscent; receptacle or axis of the fruit expanded at apex into a disk to enclose the ovary. A nat. of the Medit. region that escapes from cult. in s. Tex., flowering the year around.

12. WISSADULA MEDIC.

Perennial herbs, somewhat woody; leaves petioled, cordate, mostly entire; flowers perfect, 5-parted, small, without involucre, solitary in the axils or in terminal panicles; calyx deeply lobed; corolla yellow or white; ovary 5-celled, ovules mostly 3 in each cell; style branches 5; carpels typically 5, each 2-celled, constricted laterally so as to produce a horizontal fold, apiculate or aristate; seeds mostly 3 in each carpel, the lower one villous.

About 40 species, mostly in the American tropics.

- 1. Leaves with crenulate to serrate margins, rarely subentire; stems and floral branches with conspicuous simple glandular hairs; calyx and corolla more than 10 mm. long 1. *W. holosericea*.
- 1. Leaves with entire margins; stems and floral branches without simple glandular hairs; calyx and corolla 8 mm. long or less (2)
- 2(1). Leaves typically narrowly ovate to ovate-lanceolate, tapering to the acuminate apex, mostly truncate at base; plant densely brownish stellate-pubescent throughout; corolla white 2. *W. periplocifolia*.
- 2. Leaves typically suborbicular-ovate to broadly triangular-ovate, abruptly long-acuminate at apex, cordate at base; plant puberulent with scattered longer simple or stellate hairs; corolla yellow 3. *W. amplexissima*.

1. *Wissadula holosericea* (Scheele) Gke. Robust branching plant to about 18 dm. high, densely velvety stellate-tomentose throughout, the stems and floral branches with conspicuous simple glandular hairs, soft and white but in age usually tawny and somewhat roughish, heavy-scented; leaves broadly ovate to triangular-ovate, cordate at base, acute to acuminate at apex, to 2 dm. long and often about as broad, irregularly crenate to dentate or rarely subentire, occasionally obscurely trilobed above, conspicuously veined beneath; flowers short-peduncled, at first solitary in the lower axils, the later ones corymbose-paniculate at the summit; calyx campanulate, about 15 mm. long, the lobes ovate and acute to acuminate; petals orange-yellow, 1.2-2 cm. long; carpels tomentose, beaked, not exceeding the calyx; seeds glabrous. *W. insignis* R. E. Fries. In rocky soils on the Edwards Plateau and in the Trans-Pecos, May-Nov.; also adj. Mex.

Very similar in habit to *Pseudabutilon Lozanii* but, in addition to a distributional difference, the stem of upper part of plant and branches of inflorescences have simple glandular hairs, whereas these organs in *Pseudabutilon Lozanii* are densely nonglandular stellate-pubescent.

2. *Wissadula periplocifolia* (L.) Presl. Somewhat woody perennial, branched, densely brownish stellate-pubescent throughout, to about 1 m. high; leaves ovate-lanceolate to

lanceolate, entire, truncate to rounded or rarely subcordate at base, gradually long-acuminate at apex, light-tawny beneath, the lower leaves slender-petioled and 5-15 cm. long, the upper smaller leaves short-petioled; flowers solitary in the axils and in terminal panicle to 2 dm. long; pedicels filiform, to 5 cm. long, usually much shorter; calyx 3-4 mm. long; petals white, obovate, about twice as long as the calyx; carpels dark-brown to blackish, apiculate, 6-8 mm. long. Incl. var. *gracillima* R. E. Fries. In woodlands and sacahuista grasslands in s. Tex., flowering throughout year; from Tex., s. to n. S.A. and the W.I.

3. *Wissadula amplissima* (L.) Fries. Perennial woody plants with erect branches, to about 2 m. high, more or less puberulent throughout and with scattered longer simple or stellate hairs; leaves broadly ovate, thin, very pale beneath, entire, sometimes with short acute lateral lobules above middle, cordate at base, acute to acuminate at apex, the lower leaves slender-petioled and 5-15 cm. long, the upper smaller leaves nearly sessile; flowers forming axillary and terminal panicles; pedicels slender, elongate or short, to 3 cm. long; calyx 3-4 mm. long; petals yellow, 4-6 mm. long; carpels 4 or 5, 7-8 mm. long, short-beaked, puberulent, brownish. In palm groves in the Rio Grande Valley, Sept.-Dec.; from Tex., s. to S.A. and the W.I., also Afr.

13. PSEUDABUTILON R. E. FRIES

About 15 species from Texas to Argentina and the West Indies.

1. *Pseudabutilon Lozanii* (Rose) R. E. Fries. Plant subshrubby, to about 15 dm. high; branches terete, covered with stellate or dendritic hairs; leaves with stoutish petioles, suborbicular-ovate to triangular-ovate, sometimes obscurely 3-lobate above, 5-17 cm. long and often about as wide, obtuse to acute at apex, cordate at base, densely stellate-tomentose (especially beneath), with crenate margins; flowers axillary and in panicles; pedicels stout, to 3 cm. long, usually much shorter; fruiting calyx campanulate, 1-1.2 cm. long, the lobes ovate and acute; petals yellow, obovate-cuneate, about 2 cm. long; carpels 5, about 8 mm. long, short-beaked, falsely 2-celled, the 2 cavities separated by a membranous tongue-like projection (endoglossum) from the dorsal wall; seeds 3. In clay soils in thickets and open grassy areas from e. Edwards Plateau s. to coast and the Rio Grande Valley, flowering throughout year; also n.e. Mex.

The similarity of this species to *Wissadula holosericea* is discussed under that species.

14. HERISSANTIA MEDIC.

A monotypic genus.

1. *Herissantia crispa* (L.) Brizicky. Diffuse perennial with slender vinelike stems and branches to 1 m. long or more, velvety-tomentulose or canescent; leaves thin, with petioles equaling the blades or shorter, ovate, deeply cordate at base, mostly abruptly acuminate at apex, often prominently reticulate-veined, with crenulate margins, 2-7 cm. long, the uppermost leaves becoming nearly sessile; involucels none; peduncles in fruit commonly refracted at the joint; calyx lobes 5, velvety and often villous, ovate to ovate-lanceolate, acute, 4-6 mm. long; petals 5, about twice as long as the calyx, pale-yellow to whitish or sometimes yellowish-orange; fruit globose, 1-2 cm. thick; carpels about 12, rounded and muticous, becoming greatly inflated, the walls thin and papery, normally hirsute with long hairs; ovules 2 to 6 in each carpel; seeds glabrous. *Bogenhardia crispa* (L.) Kearns., *Abutilon crispum* (L.) Sweet, *Gayoides crispum* (L.) Small. In chaparral, brushland, boulder-strewn areas, flats and rocky slopes in cen., s. and w. Tex., flowering throughout the year; from Ariz. to Tex. and Fla., s. through trop. Am.; also trop. Asia.

15. ABUTILON MILL.¹²⁷ INDIAN-MALLOW

Plants herbaceous, suffrutescent or shrubby, canescent or tomentose with short stellate hairs or hirsute with longer simple hairs; leaves crenate or dentate, not or obscurely lobed;

¹²⁷ Key adapted from T. H. Kearney in Leaf. West. Bot. 7:241-254. 1955.

flowers solitary in the axils or in leafy panicles; involucre none; corolla usually orange or yellow; fruit truncate-cylindric or ovoid, the carpels with smooth sides, dehiscent nearly to the base when mature; ovules 2 or more in each carpel.

About 100 species widespread mostly in tropical and subtropical regions.

1. Carpels normally 5 (sometimes 6 in *A. incanum*), usually with few ovules (2)
1. Carpels more than 5 (6)
 - 2(1). Petals about 20 mm. long and 10 mm. wide; herbage whitish-velutinous with stellate hairs; leaves broadly ovate, deeply cordate, acuminate, coarsely dentate; flowers in a small terminal subcorymbose cluster; calyx about 9 mm. long, the lobes ovate-lanceolate and cuspidate 1. *A. Marshii*.
 2. Petals not more than 12 mm. long (3)
 - 3(2). Stems obtusely trigonous and deeply sulcate above; herbage finely stellate-tomentose, also more or less glandular-puberulent and rarely with a few long simple hairs; leaves long-petiolate, cordate, rather abruptly long-acuminate, crenate or subentire; flowers in a very open leafy panicle; calyx less than one half as long as the carpels, spreading or reflexed in fruit; corolla yellow, often with a dark center, the petals about 5 mm. long; fruit truncate, the carpels often slightly constricted at about the middle or above the base, mucronate to cuspidate 2. *A. trisulcatum*.
 3. Stems terete or (if more or less angulate-sulcate) the other characters not combined as above (4)
 - 4(3). Calyx erect in fruit, often almost as long as the carpels; herbage finely tomentose; inflorescence (when well-developed) an elongate leafy many-flowered panicle; carpels 6-9 mm. long, rounded to obtuse at the apex, rather coarsely stellate-pubescent 3. *A. malacum*.
 4. Calyx spreading or reflexed in fruit, much shorter than the carpels; petals usually without basal spots (5)
 - 5(4). Petals 6-9 mm. long, yellow or orange; carpels 6-8 mm. long, mucicous or apiculate, rarely cuspidate, finely stellulate; plant usually suffrutescent; stems erect, minutely tomentose, sometimes triquetous above; leaves often more than 3 (to 7) cm. long, denticulate to coarsely dentate; flowers numerous, often somewhat congested at the ends of the branches 4. *A. incanum*.
 5. Petals 4-6 mm. long, orange-pink or red; carpels 8-9 mm. long, mucronate or cuspidate; plant herbaceous above the crown; stems spreading or decumbent, with spreading hairs, often vinelike; leaves not more (usually less) than 3 cm. long, usually coarsely dentate; flowers few, solitary in the axils 5. *A. parvulum*.
 - 6(1). Corolla typically rose-pink (at least when fresh), rarely white; stems and petioles with long wide-spreading coarse hairs 6. *A. Hulseanum*.
 6. Corolla yellow or orange-color, rarely whitish, with or without a darker center; stems and petioles rarely with long wide-spreading fine hairs (7)
 - 7(6). Plant annual; stems to 1 m. high; herbage more or less tomentose; leaves large, broadly ovate to suborbicular, abruptly acuminate; petals about 1 cm. long, yellow; carpels long-aristate, with many ovules 7. *A. Theophrasti*.
 7. Plants perennial, often more or less woody (8)
 - 8(7). Fruiting calyx not more than two thirds as long as the mature fruit (9)
 8. Fruiting calyx from more than two thirds as long as to longer than the mature fruit (10)
 - 9(8). Carpels mucicous or only shortly cuspidate; flowers in very open panicles 8. *A. sonora*.
 9. Carpels long-beaked or aristate 9. *A. umbellatum*.
 - 10(8). Corolla usually less than 15 mm. long (11)
 10. Corolla usually 15 mm. long or more (12)

- 11(10). Calyx lobes subcordate and overlapping at base (at least in the bud) 10. *A. lignosum*.
11. Calyx lobes not subcordate at base; seeds usually minutely tuberculate or echinate .. 9. *A. umbellatum*.
- 12(10). Stems with few or many long spreading simple hairs in addition to other pubescence 11. *A. Wrightii*.
12. Stems without such hairs (13)
- 13(12). Leaves to 5 cm. long, obtuse to shortly acuminate, crenulate, sometimes obscurely trilobate, moderately discolorous; carpels cuspidate; calyx about one half as long as the corolla, its lobes deltoid and somewhat overlapping at the base; plant shrubby 12. *A. glabriflorum*.
13. Leaves mostly larger than those above, attenuate-acuminate; carpels long-beaked or aristate 13. *A. hypoleucum*.

1. *Abutilon Marshii* Standl. Plant erect, densely whitish-velutinous with stellate hairs; leaves with long slender stellate-pilose petioles 7-9.5 cm. long, broadly ovate, about 13 cm. long and 1 dm. wide, obscurely 3-lobed, deeply cordate at base, long-acuminate at apex, coarsely crenate-dentate, stellate-pilose; flowers few in a small subterminal corymbose cluster, with short thick pedicels; calyx 8-9 mm. long, densely stellate-pilose, deeply lobed, the lobes ovate-lanceolate and shortly subulate-acuminate; petals about 2 cm. long and 1 cm. wide; fruit unknown. In the Chisos Mts. of the Trans-Pecos, Aug., endemic.

2. *Abutilon trisulcatum* (Jacq.) Urban. AMANTILLO. Shrub to about 15 dm. high, with slender ascending densely tomentulose 3-angled branches; leaves ovate, slender-petioled, cordate at base, abruptly acuminate at apex, to 12 cm. long, crenate to crenulate, finely velvety on both sides, the upper leaves smaller than the lower ones; flowers solitary and slender-peduncled in the axils of leaflike bracts or subpaniculate; calyx 4-5 mm. long, its lobes triangular-ovate and acuminate; petals yellow, reddish blotched at the base, 5-7 mm. long; carpels about 5, stellate-puberulent, short-tipped, about 8 mm. long. *A. triquetrum* (L.) Sweet, *A. Nealleyi* Coult. In palm groves and thickets in s. Tex., Jan.-Apr.; from Tex. to Mex. and W.I.

3. *Abutilon malacum* Wats. Plant tall, suffrutescent and branching, the stems rather stout, very finely and closely velvety-pubescent throughout; leaves long-petioled, suborbicular-ovate, cordate at base, acute at apex, irregularly dentate, to about 1 dm. long, about as long as the petiole; panicles axillary and terminal; flowers numerous and short-pedicelled; calyx lobes lanceolate, acute to acuminate, 6-8 mm. long; petals orange-color, about twice as long as the calyx; carpels 5, acutish, coarsely stellate-pubescent, about as long as calyx. On rocky hills, dry slopes and gravelly flats in w. Tex., June-Sept.; also N.M. and adj. Mex.

4. *Abutilon incanum* (Link) Sweet. PELOTAZO. Plant herbaceous, more or less branched above, minutely tomentose, to about 6 dm. high; leaves thickish, mostly ovate-cordate, acute to acuminate, irregularly serrate, to 1 dm. long, smaller on the branchlets; flowers solitary and mostly slender-peduncled in the axils and sometimes loosely and slightly paniculate on the branchlets; calyx 2-4 mm. long, at length usually reflexed under the more or less oblong truncate canescent-puberulent capsule; petals orange-yellow, 6-10 mm. long; carpels 5 (or 6), muticous or nearly so; seeds when young smooth and glabrous, in age minutely cinereous-pubescent. *A. Nuttalli* T. & G., *A. ramosissimum* Presl, *A. texense* T. & G. In dry areas on cliffs, slopes, prairies, and in open woods and chaparral in w. half of Tex., throughout the year; from Tex. to Ariz. and Mex.

5. *Abutilon parvulum* Gray. Stems slender and spreading or trailing, from a woody root, paniculate above, cinereous-tomentose with a lax minute stellate pubescence, the branchlets pilose with spreading hairs; leaves thin, small, to 5 cm. long, broadly ovate, cordate at base, dentate, sometimes obscurely 3-lobed, usually obtuse at apex; peduncles filiform, axillary, 1-flowered, longer than the leaves; calyx lobes ovate, acuminate, reflexed in fruit; petals pink or red, sometimes orange-color or yellowish, 4-6 mm. long, exceeding the calyx; carpels 5, somewhat tomentose, erect and acute, to about 8 mm. long. On limestone hills, dry ledges, mesas and similar areas on the Edwards Plateau

and in the Plains Country and Trans-Pecos, May-Nov.; from Tex. to Colo., Calif. and n. Mex.

6. *Abutilon Hulseanum* (T.&G.) Chapm. Shrub to about 1 m. high, densely velvety-tomentose, the branches and stalks villous or hirsute with spreading hairs; leaves long-petioled, broadly ovate, rather abruptly acute to acuminate, 5-12 cm. long, irregularly crenulate, acute at apex, deeply cordate at base, the lower surface densely canescent; flowers axillary, solitary or short-paniculate; peduncles equal to or surpassing the petioles, 5-10 cm. long; calyx deeply 5-cleft, about 13 mm. long, with reduplicate-angled base, the lobes ovate and acute; petals white, fading to rose-color, 13 mm. long or more, slightly exceeding the calyx; carpels 12 to 14, swollen, black, apiculate. *A. commutatum* K. Schum., *A. leucophaeum* Hochr. Thickets in palm groves in Rio Grande Valley, Feb.-May; also adj. Mex.

7. *Abutilon Theophrasti* Medic. CHINGMA, VELVET-LEAF BUTTERPRINT. Plant annual, tall, velvety and cinereous with very short and fine soft woolliness, annual; leaves sub-orbicular-ovate, to 15 cm. or more in diameter, abruptly acuminate at apex, cordate at base, velvety-pubescent; peduncles shorter than petioles; calyx very deeply 5-parted, about half the length of the awn-beaked capsule; petals yellow, about 6 mm. long; carpels villous, usually more than 10, with long divergent awns, much-surpassing the calyx. A nat. of Euras. that has become weedy in waste and cult. grounds throughout much of N.A.; occasional in the High Plains.

8. *Abutilon sonorae* Gray. Herbaceous or suffrutescent perennial to about 15 dm. high; stems, branches and petioles with simple spreading or reflexed hairs to 3.5 mm. long; stipules linear-lanceolate, 3-5 mm. long, caducous; leaves with petioles 5-15 cm. long, broadly ovate to suborbicular, acuminate, deeply cordate at base, 5-20 cm. long and wide, shallowly trilobate or the margins merely irregularly crenate-dentate, finely and densely stellate-pubescent, dark-green above, canescent and velvety beneath; flowers in axillary and terminal panicles; peduncles 1-3 cm. long in anthesis, 1-flowered; pedicels 3-6 mm. long; calyx finely stellate-puberulent, the ovate acute lobes 3-4 mm. long; petals deep-yellow with orange tinge outside, 6-10 mm. long; carpels 7 to 11, stellate-pubescent, 8-10 mm. long, the spreading-ascending beak 0.5-1 mm. long; seeds usually 3 in each cell, about 2 mm. long, dark-brown, dull, netted with a reticulum of minute conical somewhat curved light-brown hairs that surmount low narrow ridges. In canyons and at base of bluffs in the Trans-Pecos, July-Sept.; from w. Tex. to s. Ariz., s. in Mex. to Gro.

9. *Abutilon umbellatum* (L.) Sweet. Perennial, somewhat woody, erect, usually branched, stellate-tomentose (at least above), to about 9 dm. high; leaves long-petioled, broadly ovate, abruptly acute to acuminate, cordate at base, 4-10 cm. long, stellate-pubescent or puberulent, coarsely crenate-dentate; flowers corymbose or subumbellate, sometimes densely clustered; calyx campanulate, about 6 mm. long in flower; petals yellow, 8-10 mm. long; carpels usually 6 or 7, stellate-hirsute, about 7 mm. long, biaristate. On edge of and in open woods in s. Tex., Sept.-Dec.; also W.I. and Mex. to S.A.

10. *Abutilon lignosum* (Cav.) D. Don. Plant shrubby, branched, densely stellate-tomentose, erect, to 15 dm. high; leaves slender-petioled, orbicular-ovate, stellate-tomentose, dentate or denticulate, acute to acuminate at apex, cordate at base, to about 1 dm. long; flowers axillary, solitary on peduncles mostly longer than the petioles; calyx about 1 cm. long, tomentose, deeply 5-parted, its lobes broadly ovate to ovate-lanceolate and acute to acuminate; petals yellow to orange-color, slightly longer than the calyx; carpels 7 to 10, swollen, beaked, stellate-pubescent, about 15 mm. long. *A. Berlandieri* Gray, *A. abutiloides* (Jacq.) K. Schum., illegit. name, *A. americanum* (L.) Sweet. In waste ground, chaparral and cult. areas in s. Tex.; also n. Mex. and the W.I.

11. *Abutilon Wrightii* Gray. Plant herbaceous from a woody stock, to about 6 dm. high, ascending or decumbent, branching, viscid-pubescent and villous with fine spreading hairs; leaves thin, long-petioled, ovate-cordate, obtuse to acutish at apex, sharply dentate above, to 5 cm. long, greenish and scabrous-velvety above, very soft white-tomentose below; axillary peduncles mostly 1-flowered, equal to the petioles or the upper ones exceeding the leaves; calyx tomentose, 5-parted, angulate at base, about 13 mm. long, with very acuminate divisions that about equal the yellow petals; carpels thin, tomentulose, subulate-beaked, about 12 mm. long; seeds smooth and glabrous. On

talus slopes, rocky hills, ledges and cliffs, and in chaparral, draws and arroyos on the Edwards Plateau and in s. and w. Tex., Mar.-Nov.; from Tex. to Ariz.

12. *Abutilon glabriflorum* Hochr. Shrub with fruticose stems, glabrate in age; leaves broadly cordate, 3.5-7 cm. long, acute to acuminate, shallowly crenate or denticulate, densely stellate-pubescent, whitish beneath; sepals broadly ovate, acute; petals 1.5-2 cm. long; carpels 1-1.2 cm. long. In the Rio Grande Valley of s. Tex.; adj. Mex.

13. *Abutilon hypoleucum* Gray. Shrub with branching stems to 12 dm. high, subglabrous to white-tomentose; leaves slender-petioled, broadly ovate, cordate at base, abruptly narrowed and gradually acuminate at apex, erose-serrate, very soft white-tomentose and veiny beneath, green and scabrous-pubescent to somewhat velvety above, 5-7.5 cm. long; axillary peduncles mostly 1-flowered and exceeding the petioles; calyx white-tomentose, 5-parted and -angled, of seemingly cordate acuminate sepals; petals yellow, slightly exceeding the calyx; carpels numerous, subulately erect-awned and villous-hirsute, 12 mm. long or more. In palm groves and canyons in the Rio Grande Plains and Valley, Mar.-Oct.; adj. Mex.

Distinguished by its seemingly cordate sepals equaling the hirsute erect-awned carpels.

16. MODIOLA MOENCH

A monotypic genus.

1. *Modiola caroliniana* (L.) G. Don. Low creeping diffuse chiefly perennial herb, hirsute with simple or geminate hairs, to 6 dm. long or more; leaves with petioles to 3 cm. long, rounded, palmately 3- or 5-lobed and incised, to 6 cm. long and 4 cm. wide; peduncles commonly filiform and equaling or surpassing the petiole; flowers small, solitary on axillary peduncles, subtended by a persistent involucre of 3 foliaceous bractlets; petals small, salmon-color to purplish-red, obovate, 4-6 mm. long, little-surpassing the calyx; stamens 10 to 20; stigmas capitate; fruit depressed, composed of 15 to 30 thin-coriaceous carpels; carpels reniform, much-compressed, more or less hirsute, with a dorsal bipartite cusp and hispid at summit, eventually falling free from the axis and tardily bivalved at the top, eventually becoming somewhat glabrate. In waste grounds, disturbed soils, edge of salt marshes, lawns and similar places, mostly in s. Tex. but occasionally elsewhere, Mar.-May; from Fla. to Tex., n. to Va. and s. to Arg.

17. SPHAERALCEA ST.-HIL.¹²⁸

FALSE MALLOW. GLOBE MALLOW

Plants herbaceous or suffrutescent, mostly perennial, the herbage stellate-pubescent; leaves subentire to shallowly dentate or pedately dissected; inflorescences racemose or paniculate; calyx nearly always tribracteolate; corolla usually red (grenadine); fruit hemispheric to truncate-conic; carpels often remaining attached to the axis after maturity by a threadlike extension of the dorsal nerve; ovules and seeds 1 to 3 in each carpel.

About 50 species in both hemispheres. Several of the species are browsed to some extent by domestic and wild grazing animals.

1. Indehiscent reticulate part of the carpel conspicuously wider than the dehiscent part, forming two-thirds or more of the carpel (2)
1. Indehiscent reticulate part of the carpel not conspicuously wider than the dehiscent part, forming less than two-thirds of the carpel (4)
- 2(1). Plant sparsely stellate-pubescent; carpels 15 or more, with thin chartaceous walls, very deeply notched; distribution in Rio Grande Plains 1. *S. pedatifida*.
2. Plant canescent or lepidote; carpels fewer than 15, with thick coriaceous walls, not very deeply notched; distribution north and west of Rio Grande Plains (3)
- 3(2). Stems and leaves silvery-lepidote; upper linear leaf blades entire, the lower ones 3-divided or nearly so; calyx closely lepidote; carpels 7 to 9 2. *S. leptophylla*.
3. Stems and leaves canescent or more coarsely pubescent; all leaf blades deeply cleft to parted or divided; calyx villous; carpels 10 to 14 .. 3. *S. coccinea*.

¹²⁸ Adapted from T. H. Kearney in Univ. Calif. Publ. Bot. 19:1-128. 1935.

- 4(1). Stems and leaves copiously pubescent with relatively long soft felted hairs, the hairs of the stem 1-1.5 mm. long 4. *S. Lindheimeri*.
4. Stems and leaves sparsely pubescent to canescent or tomentose with relatively short hairs, the hairs of the stem usually much less than 1 mm. long (5)
- 5(4). Carpels with very thin almost scarious walls, the areolae of the reticulate part transparent; inflorescence an open long-branched panicle 5. *S. laxa*.
5. Carpels with thicker chartaceous walls, the areolae often nearly opaque; inflorescence not as above (6)
- 6(5). Indehiscent part of the carpel usually rugose or muriculate dorsally, the reticulations prominent and usually coarse (7)
6. Indehiscent part of the carpel smooth or nearly so dorsally, the reticulations usually fine and not very prominent (8)
- 7(6). Pedicels slender, the lower ones often exceeding the calyx and 1 cm. long or more; leaves rather thin, the lower surface pubescent with whitish-sericeous hairs; distribution mostly east of Trans-Pecos region 6. *S. hastulata*.
7. Pedicels stout, shorter than the calyx and rarely to 1 cm. long; leaves thickish, the lower surface more densely pubescent than the upper surface; distribution mostly in the Trans-Pecos region 7. *S. subhastata*.
- 8(6). Fruit hemispheric or nearly so; carpels three fifths to fully as wide as long; leaves and stems very sparsely stellate-pubescent ... 8. *S. digitata*.
8. Fruit truncate-conic; carpels one half to three fifths as wide as long; leaves (especially the lower surface) and stems rather copiously pubescent (9)
- 9(8). Leaves pedately cleft or parted 9. *S. Wrightii*.
9. Leaves not pedately divided (10)
- 10(9). Leaves oblong-lanceolate to linear-lanceolate, at most merely angulate or toothed near the base, not more than one third as wide as long; pubescence grayish 10. *S. angustifolia*.
10. Leaves ovate to ovate-oblong, more or less distinctly lobed, more than one third as wide as long (11)
- 11(10). Pubescence yellowish, scurfy; leaves shallowly lobed, the lateral lobes usually broad and rounded; petals 10-17 mm. long; column 6-8 mm. long; hairs of the stem very short, many-rayed 11. *S. incana*.
11. Pubescence grayish or whitish; leaves often deeply cleft, the lateral lobes triangular and often acutish; petals 8-13 mm. long; column 4-6 mm. long or (if the petals and the column longer) the hairs of the stem usually relatively long and few-rayed 12. *S. Fendleri*.

1. *Sphaeralcea pedatifida* Gray. Biennial or short-lived perennial with few slender decumbent or ascending stems from a slender taproot and small crown, green, sparsely to somewhat copiously stellate-pubescent, the stems to 7 dm. long but usually much shorter; leaves with slender petioles somewhat shorter to considerably longer than the blade, thin, sparsely stellate-pubescent, pedately parted or divided, all the divisions pinnately cleft or coarsely toothed with acute often setose-tipped teeth, the midlobe to 2 times the length of the lateral lobes, the larger blades 1.5-3 cm. long and at least equally as wide; inflorescence few-flowered, racemiform or sometimes subthyrsoid below; pedicels slender, shorter than to more than twice as long as the calyx; bractlets of the involucre often denticulate; calyx 6-9 mm. long, stellate-pubescent, with ovate-lanceolate to deltoid more or less acuminate lobes; petals orange-chrome or grenadine-pink, 8-14 mm. long; carpels 15 to 20, with thin chartaceous walls, 3-3.5 mm. long, the dehiscent portion mucous, the indehiscent portion wider than the dehiscent portion, coarsely and prominently reticulate, fenestrate, nigrescent, rugose-tuberculate or muricate dorsally. In sandy soil in scrub brushlands, on rocky-gravelly slopes and in fields on the Rio Grande Plains, Feb.-Aug.; also n. Coah.

2. *Sphaeralcea leptophylla* (Gray) Rydb. SCALY GLOBE-MALLOW. Perennial with several or numerous decumbent to ascending or erect stems from a long stout taproot and a stout woody crown, silvery-lepidote with short many-rayed appressed hairs that

form fringed scales, the stems to 5 dm. long; leaves sometimes fascicled in the lower axils, with slender petioles usually less than one third as long as the blade, rather thick, with midvein prominent beneath, usually conduplicate or with the margins revolute, the upper leaves entire, linear to narrowly oblanceolate, obtuse to acute and usually cartilaginous-apiculate at the apex, the lower leaves 3-divided or very nearly so with the midlobe 1.5-3 mm. wide and 1 to 2 times as long as the lateral divisions, one or more of the divisions sometimes 1- or 2-cleft, the larger blades 15-35 mm. long; inflorescence racemiform, with long internodes, with 12 or fewer flowers, appearing naked throughout or leafy at the base only; pedicels usually slender, much shorter than to twice as long as the calyx; involucre of 3 thick bractlets, often persisting until fruit maturity; calyx 4.5-7 mm. long, with deltoid-ovate to ovate-lanceolate and acute to short-acuminate lobes; petals grenadine, 9-15 mm. long; carpels 7 to 9, very thick, with coriaceous walls, 3-3.5 mm. long, the dehiscent portion obtuse to acute and mucicous or mucronulate at apex, the indehiscent portion much wider than the dehiscent portion, very prominently and usually coarsely reticulate, moderately rugose to slightly tuberculate dorsally. In limestone soil on hills and along roadsides in the Trans-Pecos, Mar.-Aug.; from Tex. and Colo., w. to Ut., Ariz. and n. Mex.

3. *Sphaeralcea coccinea* (Pursh) Rydb. SCARLET GLOBE-MALLOW, RED FALSE MALLOW. Perennial with usually decumbent or ascending stems from a slender or stout taproot, usually rather densely grayish or whitish stellate-pubescent throughout, the stems to 5 dm. long, usually much shorter; leaves with petioles of lowermost ones as long as or longer than the blades, usually thickish and much more pubescent on the lower than on the upper surface, broadly deltoid in outline, pedately parted or divided, the midlobe and often the primary lateral divisions pinnately few-cleft or even parted, the primary lateral divisions not less than two thirds as long as the midlobe with the latter and often the primary lateral divisions long-cuneate at base, all the divisions rounded-truncate to acutish at apex, the larger blades 1-6 cm. long and wider than long; inflorescence racemiform or occasionally subthyrsoid at base, with usually very short internodes, few- to many-flowered; pedicels usually rather stout and shorter than the calyx, the lower ones sometimes more slender and elongate; calyx conspicuously villous, 5-10 mm. long, with lanceolate to deltoid-ovate or usually ovate-lanceolate acuminate lobes; petals grenadine, 1-2 cm. long; carpels 10 to 14, very thick, with coriaceous walls, 3-3.5 mm. long and wide, the dehiscent portion mucicous and with an internal palatelike fold near the base dorsally, the indehiscent portion much wider than the dehiscent portion and very coarsely and prominently reticulate, rugose-tuberculate dorsally. On caliche outcrops and gypsum, and in gravelly-limestone and sandy-clayey soils on breaks, plains and hills in the Plains Country and Trans-Pecos, Apr.-Aug.; from cen. Can. s. to Ia., Tex., N.M. and Ariz. The variants in our region have been segregated as follows:

1. Primary lateral divisions of the leaves less than two thirds as long as the midlobe; dehiscent part of the carpel usually ascending, deltoid and acutish, forming about one-third of the whole var. *elata* (E. G. Baker) Kearn.
1. Primary lateral divisions of the leaves at least two thirds as long as the midlobe; dehiscent part of the carpel usually horizontal, irregularly quadrilateral, forming less than one-third of the whole (2)
- 2(1). Herbage usually densely whitish-canescens; leaves with very narrow divisions var. *dissecta* (Nutt.) Garrett.
2. Herbage usually green and less densely pubescent; leaves with relatively broad divisions var. *coccinea*.

4. *Sphaeralcea Lindheimeri* Gray. Perennial with few decumbent stems from a small crown, densely whitish-pubescent with relatively very long soft felted hairs, the stem to 7 dm. long; leaves with slender or stout petioles about as long as the blade, thin, deltoid-ovate to suborbicular, truncate to cordate at base, rounded to acutish at apex, usually very shallowly but sometimes deeply lobed, the margins shallowly crenate to coarsely and irregularly dentate, the larger blades 25-45 mm. long and wide or wider; inflorescence usually racemiform, at most subthyrsoid, few-flowered; pedicels slender or stout, much shorter than to twice as long as the calyx; calyx 8-15 mm. long, with

lanceolate to ovate-lanceolate attenuate-acuminate lobes; petals grenadine-pink, 13-25 mm. long; carpels about 18, with chartaceous walls, about 4 mm. long, the dehiscent portion rounded and mucicous at apex, the indehiscent portion prominently and rather coarsely reticulate, often nigrescent. In sandy soils in open woods, thickets and plains in s. and s.-coastal Tex., Feb.-June; endemic.

5. *Sphaeralcea laxa* Woot. & Standl. CALICHE GLOBE-MALLOW. Perennial with several erect or ascending stems from a thick woody crown and a stout taproot, usually densely whitish canescent or tomentose with short hairs, to about 9 dm. high; leaves with slender petioles equaling or longer than the blade of the lower leaves, mostly thinnish, broadly ovate to deltoid in outline, subcordate to deeply cordate at base, very obtuse to acutish at apex, shallowly 3-lobed to almost 3-parted, with the lateral lobes sometimes deeply cleft, the lobes usually rounded, the midlobe seldom more than twice as long as the lateral ones, the margins irregularly crenulate to crenate or coarsely dentate, the larger blades 1.5-5 cm. long and about as wide; inflorescence an open lax relatively few-flowered panicle; pedicels slender, usually much shorter than the calyx; bractlets of the involucre often dark-red and conspicuous; calyx 7-11 mm. long, with lanceolate to oblong-lanceolate acuminate lobes; petals grenadine-pink to grenadine-red, 12-18 mm. long; anthers dark-purple; carpels 12 to 14, thin-walled, 4-6 mm. long, the dehiscent portion acute to obtuse and cuspidate to mucronulate at apex, the indehiscent portion rather prominently but finely reticulate, with nearly transparent areolae. In shallow limestone soil in extreme w. Tex., May-Nov.; from Tex. to Ariz. and n. Mex.

6. *Sphaeralcea hastulata* Gray. Perennial with few or several usually decumbent stems from a small crown or from often farther below the soil surface as root-shoots, rather densely canescent to subtriglosely pubescent throughout, the stems to 3 dm. long but usually shorter; leaves with slender petioles one half as long as the blade or less, thin, with veins not very prominent beneath, usually bright-green and rather sparsely pubescent above, paler and densely sericeous-pubescent beneath, oblong-ovate to ovate-lanceolate, subcuneate to strongly cuneate or sometimes truncate or even subcordate at base, acute to short-acuminate at apex, usually merely subhastately toothed or shallowly lobed with rounded teeth or lobules less than one fifth as long as the midlobe (sometimes deeply cleft with much longer lateral lobes), the margins nearly entire to coarsely and irregularly crenate-dentate or the midlobe even pinnately cleft, the larger blades 2-6 cm. long; inflorescence racemiform with usually only one flower at each node and seldom more than 8 per stem; pedicels slender, the lower ones often much longer than the calyx, usually with some more than 1 cm. long; calyx 6-11 mm. long, with lanceolate to ovate-lanceolate acuminate lobes; petals grenadine, 1.5-2 cm. long; carpels thickish, with chartaceous walls, 3-5 mm. long, the obtuse to acute dehiscent portion usually mucicous but sometimes mucronate or cuspidate and sometimes sparsely spinulose dorsally toward apex, the indehiscent portion usually conspicuously wider than the dehiscent portion, coarsely and very prominently reticulate, often nigrescent, conspicuously muricate dorsally. In sandy or rocky soils, caliche or on salt flats mainly in w.-cen. and s. Tex., Feb.-Aug.; also n.e. Mex.

7. *Sphaeralcea subhastata* Coult. Perennial with decumbent to ascending or nearly erect stems from a slender or rather stout taproot, canescent, the stems to 5 dm. long but usually much shorter; leaves with usually slender petioles mostly less than half as long as the blade, usually thickish with veins prominent beneath, oblong-lanceolate to narrowly ovate, cuneate at base, acute to short-acuminate at apex, usually much more sparsely pubescent on the upper than on the lower surface, scarcely lobed but usually subhastately angled or toothed at base with ascending teeth, the margins nearly entire to irregularly crenate or dentate, the larger blades 2-5.5 cm. long; inflorescence racemiform or with 2 flowers at some of the lower nodes, few-flowered (mostly less than 12), usually leafy nearly to the apex; pedicels usually stout and shorter than the calyx, rarely more than 1 cm. long; calyx 4-11 mm. long, with usually ovate-lanceolate to lanceolate and attenuate-acuminate lobes; petals grenadine (rarely pink or drying violet-color), 1-1.8 cm. long; carpels thickish, with chartaceous walls, seldom connate at maturity, 4-6 mm. long, the dehiscent portion usually acute and with cusps to nearly 2 mm. long (rarely mucicous), occasionally sparsely spinulose dorsally toward apex, the indehiscent portion coarsely and very prominently reticulate, often nigrescent, rugose-tuberculate or muricate

dorsally. Incl. var. *pumila* (Woot. & Standl.) Kearn. and var. *Martii* (Cockll.) Kearn. and var. *latifolia* Kearn. In sandy or gravelly soils and on limestone slopes, frequent along roadsides, mainly in the Trans-Pecos, rare eastw., Mar.-Sept.; from Tex., w. to Ariz. and n. Mex.

8. *Sphaeralcea digitata* (Greene) Rydb. JUNIPER GLOBE-MALLOW. Perennial with slender decumbent to ascending or nearly erect stems from a stout or rather slender taproot and woody crown, more or less thinly canescent throughout, the stems to about 55 cm. long, usually much shorter; leaves with slender petioles shorter than the blades, rather thin, pedately divided or nearly so, with the primary lateral divisions so deeply parted as to give the appearance of a 5-parted leaf, all the divisions oblanceolate to narrowly obovate, cuneate at base, obtuse to acute and often mucronulate at apex, the midlobe not more than 5 mm. wide and not much longer than the primary lateral divisions, all the divisions entire or (the midlobe especially) coarsely and irregularly few-toothed or -cleft, the larger blades 1.5-4 cm. long and about as wide; inflorescence usually 10- to 20-flowered, narrowly subthyrsoid with often only the lowest nodes bearing more than 1 flower, the lowest branches not more than 2 cm. long; pedicels mostly stout and usually but not always much shorter than the calyx; calyx 3.5-7 mm. long, with ovate-lanceolate acuminate lobes; petals grenadine, 8-14 mm. long; carpels 9 to 13, thickish, with chartaceous walls, 3-4 mm. long, the acute dehiscent portion muticous to short-cuspidate, the indehiscent portion finely and usually not prominently reticulate. In rock crevices and on rocky hills in limestone and gypsum soils in the Trans-Pecos, Mar.-Nov.; from Tex. to Ut., Ariz. and n. Mex.

Those plants with usually 2 larger flowers at some of the lower nodes, and whose slender elongate pedicels typically exceed the calyx, are segregated as subsp. *tenuipes* (Woot. & Standl.) Kearn.

9. *Sphaeralcea Wrightii* Gray. Perennial with few erect or nearly erect stems from a rather small woody crown, grayish-canescenscent or subtomentose with soft hairs, to 75 cm. high; leaves with rather slender petioles that are usually as long as to much longer than the blade of the lower leaves, thickish, with veins rather prominent beneath, much more densely pubescent below than above, broadly ovate to semiorbicular in outline, truncate to deeply cordate at base, usually obtuse and often mucronulate at apex, all but the lowest leaves pedately deeply cleft or parted, the coarse wedge-shaped divisions irregularly and pinnately few-toothed or -cleft with broad usually obtuse teeth, the midlobe about twice as long as the lateral lobes, the larger blades 2-4 cm. long and wide; inflorescence a narrow few- to many-flowered interrupted thyrses; pedicels rather stout, shorter to considerably longer than the calyx; calyx 6-7 mm. long, with deltoid-ovate to ovate-lanceolate short-acuminate lobes; petals grenadine or pink, often drying lavender or violet-color, 1-1.8 cm. long; carpels 12 to 15, with chartaceous walls, sometimes slightly connate at maturity, 4-5 mm. long, the dehiscent portion very obtuse to acutish and cuspidate at apex, the indehiscent portion prominently and rather coarsely or finely reticulate. On mt. slopes in extreme w. Tex.; rare from Tex. to Ariz. and n. Mex.

10. *Sphaeralcea angustifolia* (Cav.) D. Don. Perennial with erect stout stems from a thick woody crown, more or less stellately canescent throughout, to about 18 dm. high; leaves with petioles rarely more than one fourth as long as the blade, usually thickish, lanceolate to oblong-lanceolate or linear-lanceolate, cuneate at base, obtuse to acuminate at apex, 3-veined from base, to about 15 cm. long, usually much smaller, not lobed but often angulate near the base or subhastately toothed with acutish ascending teeth, the margins usually finely and regularly crenate or crenate-dentate; inflorescence a long narrow interrupted many-flowered thyrses, conspicuously leafy nearly to the apex, the lower branches not more than 4 cm. long; pedicels usually stout and much shorter than the calyx; calyx 5-9 mm. long, the lobes lanceolate to oblong-lanceolate and acuminate; petals usually mauve or lavender (often drying violet-color) but sometimes white or grenadine, 1-2 cm. long; carpels 10 to 15, with chartaceous walls, usually strongly connate at maturity, 3.5-6.5 mm. long, the erect dehiscent portion muticous to mucronulate or sometimes short-cuspidate or spinulose at apex, the indehiscent portion very finely reticulate. In sandy or rocky soils, mostly limestone and gypsum, waste places and along roadsides, mainly in the Trans-Pecos and Rio Grande Plains, less common eastw., throughout the year; from Kan. and Colo., s. to Tex., Ariz. and Mex. The variants in our region have been segregated as follows:

1. Petals usually pink or lavender; carpels usually obtuse, mucicous or mucronulate; leaf blades only angulate or obscurely toothed near the base
.....var. *angustifolia*.
1. Petals usually grenadine; carpels usually acutish, mucronate or cuspidate; leaf blades distinctly toothed or short-lobed near the base (2)
- 2(1). Leaf blades not more than one third as wide as long, with subhastate teeth usually less than one tenth as long as the midlobevar. *cuspidata* Gray.
2. Leaf blades one third to one half as wide as long, with subhastate lobes one tenth to one fifth as long as the midlobevar. *lobata* (Woot.) Kern.

11. *Sphaeralcea incana* Torr. Perennial with several to many erect stems from a stout woody crown and a large taproot, very densely yellowish-canescens with very short scurfy hairs, the stems to 18 dm. high; leaves with stout petioles shorter than the blades, typically yellowish-green, usually rather thick and with veins prominent beneath, deltoid-ovate, usually truncate to subcordate at base, very obtuse to slightly retuse and often mucronulate at apex, scarcely lobed to very shallowly 3- to 5-lobed with broad rounded lobes usually at or near the middle, the midlobe seldom less than 5 times the length of the lateral lobes, the margins usually crenulate but sometimes irregularly and rather coarsely crenate or dentate, the larger blades 3-7 cm. long and about as wide; inflorescence a long narrow interrupted many-flowered thyse, the lower branches seldom more than 3 cm. long; pedicels rather slender but exceptionally tough and persistent, shorter to much longer than the calyx; bractlets of the involucl thickish, not becoming red or purple; calyx 3.5-6.5 mm. long, with deltoid-ovate to ovate-lanceolate acute to short-acuminate lobes; petals grenadine-pink, 1-1.7 cm. long, often well-separated at base; carpels 11 to 14, with chartaceous walls, usually not connate at maturity, 4-5 mm. long, the dehiscent portion obtuse to acutish and cuspidate, the indehiscent portion faintly or rather prominently and usually finely reticulate. On grassy-rocky slopes, sandy soils, among boulders and on gravelly-clay flats in the Trans-Pecos, June-Oct.; from Tex. to Ariz. and n. Mex.

12. *Sphaeralcea Fendleri* Gray. Perennial with several erect or ascending stems from a woody crown, green and sparsely pubescent to densely grayish- or whitish-canescens with usually very short hairs, the stems to 14 dm. high; leaves with slender petioles usually less than one half as long as blade, thin or thickish, grayish-green, usually dark-green above, lighter colored and often densely whitish-canescens beneath, ovate-oblong to very broadly ovate, usually strongly cuneate at base, acute to obtuse and often mucronulate at apex, very shallowly to very deeply 3-lobed below the middle with relatively narrow triangular or nearly rectangular usually ascending acutish lateral lobes about one fourth as long as the midlobe, the midlobe sometimes coarsely and irregularly few-toothed or -cleft, the margins coarsely to finely crenate or crenate-dentate, the larger blades 3-6 cm. long; inflorescence a very narrow interrupted many-flowered thyse, the lower branches not exceeding 3 cm. long and usually much shorter; pedicels slender but very tough and persistent, usually equaling or longer than the calyx; bractlets of the involucl thin, usually green; calyx 4.5-6 mm. long or rarely more, with deltoid to ovate-lanceolate and acute to short-acuminate lobes; petals grenadine or occasionally grenadine-pink, rarely mauve, drying violet-color, 8-13 mm. long; carpels 11 to 15, with chartaceous walls, often somewhat connate at maturity, 4-5 mm. long, the dehiscent portion usually very obtuse and cuspidate, the indehiscent portion usually faintly and very finely reticulate. Uncommon in gravelly soils and about boulders in mts. of the Trans-Pecos, Apr.-Nov.; from s. Colo. and w. Tex. to Ariz. and n. Mex.

18. MALVASTRUM GRAY

Plants annual or perennial, herbaceous or shrubby, sparsely to densely stellate-pubescent or hispid; leaves ovate to orbicular, crenate or palmately cleft; flowers axillary or in terminal bracted inflorescences; calyx subtended by an involucl of narrow or foliaceous bractlets; petals yellow or purple; carpels few, compressed or somewhat turgid, rugose on the sides, sometimes tuberculate or aristate on the back, indehiscent.

About a dozen species that are native to tropics and subtropics of America.

1. Flowers mostly in capitate or spicate terminal inflorescences; carpels blunt
.....1. *M. americanum*.
1. Flowers mostly solitary in the leaf axils, rarely with some capitate (2)
- 2(1). Petals about 10 mm. long; carpels about 3 mm. long, aristate; stems and branches
not lepidote-stellate2. *M. coromandelianum*.
2. Petals 15 mm. long or more; carpels about 5 mm. long, not aristate; stems and
branches shortly lepidote-stellate3. *M. aurantiacum*.

1. *Malvastrum americanum* (L.) Torr. MALVA LOCA. Perennial, erect, stout, branched, usually densely stellate-pubescent, to about 2 m. high; leaves broadly ovate, serrate, stellate-pubescent, acute to acuminate at apex, subtruncate to obtuse at base, the lower leaves long-petioled and to 7 cm. long, the upper leaves smaller; flowers in dense terminal cylindrical spikes 5-12 cm. long and 15-25 mm. thick, with sometimes a few in the upper axils; bractlets 5-7 mm. long; calyx barbately hirsute or hispid, about 5 mm. long, the lobes acuminate; petals yellow to orange-yellow, about 7 mm. long; carpels nearly 2 mm. long, depressed-reniform, beaked, not aristate. *M. spicatum* (L.) Gray. A pantrop. weedy plant in palm groves, thickets, old lake beds and open woods in the Rio Grande Plains and Valley, flowering the year around.

2. *Malvastrum coromandelianum* (L.) Gke. Perennial, freely branched, strigose-pubescent, to about 1 m. high; leaves slender-petioled, ovate to ovate-oblong or lanceolate, 2-8 cm. long, acute, irregularly and sharply serrate, the hairs of the upper surfaces mostly simple; flowers mostly solitary in the axils, on peduncles shorter than the petioles; involuclers of 3 small narrow bractlets; calyx lobes triangular, acute, longer than the tube; petals pale-yellow to orange-color, somewhat longer than the calyx, obliquely truncate; carpels 8 to 12, hirsute on top, with an awn near the inflexed apex and 2 beaks on the back. *M. tricuspidatum* (Ait.) Gray. A pantrop. weedy plant on the Edwards Plateau and in s. Tex., mostly in clay soils, flowering the year around.

3. *Malvastrum aurantiacum* (Scheele) Walp. Plant with rigid stems ascending from a lignescent base, to about 6 dm. high, sparingly branched; leaves slender-petioled, subcordate-oval to oblong, broadly cuneate to truncate at base, obtuse at apex, rather coarsely crenate-serrate; bractlets of the involucler ovate or subcordate, adnate to base of calyx and more or less surpassed by the ovate-acuminate calyx lobes; petals golden-yellow, about 13 mm. long; carpels 15 to 20, firm-coriaceous, much-compressed, brownish-red at maturity, smooth, the narrow back flat with acutish angles, hirsute at top where it is dorsally 2-gibbous and ventrally subulate-aristate or pointed. *M. Wrightii* Gray. Rare in cen. and s. Tex., Apr.-Sept.; undoubtedly also in Mex. adj. to Cameron Co.

19. BASTARDIA KUNTH

About 8 species in tropical or warm temperate America.

1. *Bastardia viscosa* (L.) H.B.K. Perennial herb or subshrub, erect, to about 1 m. high, branched, finely velvety-pubescent and viscid (especially above), sometimes also pilose; leaves with slender petioles about as long as blades or shorter, ovate, cordate at base, acute to abruptly long-acuminate at apex, to 8 cm. long, the margins irregularly sinuate-denticulate, paler beneath and stellate-tomentulose; peduncular pedicels nearly filiform, usually longer than the petioles and often longer than the leaves; flowers small, peduncled, solitary or few in the axils; involucre none; calyx about 4 mm. long, its 5 ovate-lanceolate acuminate lobes about as long as the tube; petals 5, yellow, 4-6 mm. long; stamen column divided into several or many filaments at the apex; ovary 5-celled; style branches 5, the stigmas capitate; capsule depressed-globose, 5-grooved, about twice as long as the calyx, its usually 5 carpel valves beakless; seeds puberulent. *Sida viscosa* L. In clay soils in chaparral, palm groves and thickets in the Rio Grande Valley, flowering throughout the year; from Tex., s. through Mex., C.A. and the W.I. to S.A.

20. GAYA H.B.K.

About 20 species with one in Texas, the others in the American tropics.

1. *Gaya violacea* Rose. Shrub slender, erect, to about 2 m. high, the branches clothed with short soft pubescence together with long spreading hairs; leaves with petioles 4-6 cm. long, ovate to lanceolate, acuminate, 6-9 cm. long, coarsely crenate, cordate at base with the sinus either narrow or closed, green and becoming glabrate above, pale and finely stellate-pubescent beneath; peduncles slender, a little shorter than the petioles, pilose as well as stellate-pubescent; flowers in axils; calyx lobes ovate, acute; petals about 8 mm. long, blue or violet; carpels 9, each 1-seeded, membranaceous, bivalvate, with a longitudinal endoglossum that usually more or less divides the cavity of the carpel. Among boulders and rubble below the "Window" in the Chisos Mts., Oct.-Nov.; also n. Mex.

21. SIDA L.¹²⁹

Plants mostly perennial, herbaceous or suffrutescent, more or less pubescent with forked stellate or scalelike hairs; flowers axillary, solitary or in small cymules, these sometimes assembled in terminal leafy panicles; involucl usually none; carpels indehiscent or dehiscent only part way from the apex, more or less rugose and often reticulate on the sides.

More than 200 species, mostly in warmer regions of the world, especially in Latin America.

1. Peduncles or pedicels adnate to the petiole of the subtending leaf or bract; leaves sparingly serrate toward apex, mostly narrow, linear to narrowly oblong or suborbicular; flowers mostly in dense but few-flowered apical clusters that are closely subtended by the upper leaves and the conspicuously hirsute-ciliate stipules; carpels 5 to 8, with usually short murications 1. *S. ciliaris*.

1. Peduncles or pedicels not so adnate (2)

2(1). Involucl present or the herbage silvery-lepidote or the leaves wider than long; flowers axillary, solitary or very few in the axils; carpels muticous or short-beaked (3)

2. Involucl none; herbage not silvery-lepidote; leaves mostly longer than wide (6)

3(2). Plants herbaceous, the flowering stems from creeping rootstocks; leaves very asymmetric at base; flowers distinctly pedicelled, the pedicels often more or less flexuous and decurved; petals white or whitish; carpels 6 to 10 (4)

3. Plants suffrutescent; leaves not noticeably asymmetric; flowers sessile to shortly pedicellate; petals yellow or copper-colored; carpels normally 5 (5)

4(3). Herbage densely stellate-canescens; leaves wider than long, suborbicular or somewhat flabelliform, rounded at apex, rather regularly denticulate or dentate; involucl of 1 to 3 subulate bractlets, usually present but very caducous; carpels indehiscent 2. *S. hederacea*.

4. Herbage closely silvery-lepidote; leaves mostly longer than wide, acutish to acuminate at apex, often subhastately toothed or lobed at base; involucl rarely (if ever) present; carpels dehiscent at apex 3. *S. leprosa*.

5(3). Leaves flabelliform, more or less cuneate at base; carpels with 2 protracted apical peaks 4. *S. Grayana*.

5. Leaves suborbicular, rounded to truncate at base; carpels bluntly peaked, not protracted 5. *S. Helleri*.

6(2). Calyx greatly accrescent to enclose the fruit, membranous and veiny, the broad lobes overlapping; plants herbaceous above ground; flowers solitary in the axils; petals yellow or whitish 6. *S. physocalyx*.

6. Calyx otherwise, only moderately accrescent (7)

¹²⁹ Based, in part, on I. D. Clement in Contr. Gray Herb. 180:1-91. 1957.

- 7(6). Flowers mostly in open (or sometimes thyrsoid) more or less leafy panicles, numerous, usually long-pedicellate; petals less than 1 cm. long; carpels few 7. *S. paniculata*.
7. Flowers not in many-flowered panicles or (if so) then short-pedicellate and crowded, or if paniculate and long-pedicellate then the flowers few and scattered (8)
- 8(7). Carpels 5 (9)
8. Carpels more than 5 (10)
- 9(8). Herbage usually with both stellate pubescence and long simple hairs; petiole without a tubercle at base; pedicels very slender, usually elongate; calyx more or less angulate-turbinate; petals yellowish to orange 8. *S. filicaulis*.
9. Herbage minutely stellate-puberulent; petiole of largest leaves with a small spine-like tubercle at base; pedicels relatively stout, usually very short, the flowers often subsessile; petals pale-yellow 9. *S. spinosa*.
- 10(8). Corolla violet-purple; stems woody, stellate-pubescent; leaves linear to oblong, mostly 3 or more times as long as wide; flowers solitary; peduncles slender, articulated toward apex, elongate (often surpassing the subtending leaves); carpels 7 to 10, prominently rugose-reticulate 10. *S. filipes*.
10. Corolla whitish to orange or pink, sometimes drying red (11)
- 11(10). Carpels normally long-aristate and the awns retrorsely hispid; leaves not rhombic; stems usually herbaceous, occasionally with long spreading simple hairs in addition to other pubescence 11. *S. cordifolia*.
11. Carpels not long-aristate or (if sometimes so as in *S. rhombifolia*) the awns not retrorsely hispid and the leaves usually more or less rhombic (12)
- 12(11). Peduncles usually equaling or surpassing the subtending leaves, these often much-reduced in the inflorescence; flowers solitary in the axils; leaves not rhombic; carpels about 10 (13)
12. Peduncles usually much shorter than the subtending leaves (sometimes with exceptions in *S. rhombifolia* and *S. tragiaefolia*) (14)
- 13(12). Peduncles to 5 cm. long; carpels cuspidate, puberulent or glabrate, prominently rugose-reticulate 12. *S. Lindheimeri*.
13. Peduncles 7.5-15 cm. long; carpels muticous, glabrous 13. *S. longipes*.
- 14(12). Leaves normally more or less rhombic and cuneate at base, lanceolate to ovate or obovate, finely serrate, discolorous, short-petiolate; plants herbaceous or suffrutescent, rarely shrubby; herbage and calyx finely stellate-pubescent or glabrate; stipules more or less persistent; flowers axillary, solitary or more or less aggregated at ends of the branchlets, the peduncles much shorter than to nearly equaling the leaves; petals somewhat longer than the calyx, yellow or whitish, sometimes purplish at base; carpels mostly 10 to 14, nearly muticous to long-aristate, with glabrous or antrorsely pilosulous awns 14. *S. rhombifolia*.
14. Leaves not rhombic or cuneate, serrate or crenate (15)
- 15(14). Upper leaves often greatly reduced and the inflorescence appearing elongate-racemose; peduncles often longer than the subtending leaves; leaves prevailingly ovate to oblong-lanceolate, truncate to subcordate at base, crenate or crenate-serrate, often coarsely so; plant often suffrutescent; calyx puberulent to villous; petals orange or yellow, 1-1.5 cm. long 15. *S. tragiaefolia*.
15. Upper leaves usually not greatly reduced; peduncles shorter (usually much shorter) than the subtending leaves; leaves narrower, rounded at subcuneate at base, finely serrate or serrulate; plant herbaceous 16. *S. neomexicana*.

1. *Sida ciliaris* L. **BRACTED SIDA**. Diffuse many-stemmed herb or subshrub to about 3 dm. high, mostly spreading-prostrate, stellately strigose-pubescent; leaves long-petioled, linear to suborbicular, obtuse to truncate-retuse and often with a cusp at apex, rounded to cordate at base, serrate above the middle, to 25 mm. long, glabrous above, stellately

appressed-pubescent beneath; stipules filiform- or spatulate-linear, conspicuous, at least the uppermost and the petioles hirsute-ciliate or barbate; calyx 5-7 mm. long, the lobes ovate-triangular; petals white to yellow or various salmon-color to rose-purple, to 15 mm. long; carpels 5 to 8, turgid, very strongly rugose-reticulated and over the back often tuberculate or muricate, the dehiscent apex 1- or 2-aristate. In sandy soils of pastures, scrub oaks, mesquite thickets and along roadsides and on clay flats in s. Tex., throughout the year; from Fla., Tex., the Bah. I. and W.I., s. to S.A. Two variants occur in Texas.

Var. *ciliaris* (*S. muricata* Cav.)—Leaves ovate to suborbicular, obtuse to truncate at apex; carpels shortly biaristate.

Var. *mexicana* (Moric.) Shinnery—Leaves linear to linear-lanceolate; carpels short-aristate.

2. *Sida hederacea* (Hook.) Gray. DOLLAR WEED, ALKALI MALLOW. Plant with decumbent stems and branches, scurfy-canescens with stellate hairs; leaves with petioles about one half as long as blades, obliquely subreniform or triangular-ovate, more or less cordate at base, broadly rounded to bluntly obtuse at apex, to about 4 cm. long and 5 cm. wide, the margins variably and irregularly crenate to acute-serrate; flowers axillary, with pedicels usually slightly longer than the petioles; calyx 4-8 mm. long, the lobes ovate to triangular-lanceolate and short-acuminate; petals whitish to cream-color or pale-brownish-yellow, rose-color in drying, to about 15 mm. long; carpels 6 to 10, acutish, tomentulose to glabrate. *S. leprosa* var. *hederacea* (Dougl.) K. Schum. In rocky or silty soils, along irrigation canals and in depressions in the Panhandle and Trans-Pecos, Mar.-Oct.; from Wash. and Ida., s. to Mex. and e. to Kan., Okla. and Tex.

3. *Sida leprosa* (Ort.) K. Schum. SCURFY SIDA. Low herb with stems commonly prostrate and to about 4 dm. long, scurfy-lepidote throughout, silvery when young; leaves slender-petioled, obliquely deltoid to triangular-lanceolate, commonly semicordate or semisagittate at base, mostly acute at apex, irregularly or incisely dentate, to about 35 mm. long; lower pedicels usually elongated and (in fruit) deflexed with the apex incurved; calyx 3-8 mm. long, deeply divided into ovate acuminate lobes, somewhat ampliate and angulate in age; petals purple to yellow or white with a purple tinge; carpels 8 or 9, thin-walled, mucous, glabrous. In igneous soils, on clay flats and rocky areas from cen. to w. Tex., throughout the year; widespread in s.w. U.S. and Tex.

Two varieties are recognized in Texas.

1. Leaves deltoid, semicordate at base, mostly 1-3 cm. long, the upper margins irregularly notched and toothedvar. *depauperata* (Gray)

I. Clem. (*S. lepidota* Gray).

1. Leaves narrowly elongate-triangular, semisagittate at base, mostly 2-3 cm. long, the upper margins entire and straightvar. *sagittaeifolia* (Gray) I. Clem.

4. *Sida Grayana* I. Clem. Assurgent tomentulose-canescens subshrub, much-branched, the prostrate to ascending stems to 45 cm. long or more; leaves with petioles usually less than 6 mm. long, flabelliform to cuneiform or some rotund with barely cuneate base, repand-dentate or crenulate around the broad summit, to 16 mm. long and wide; stipules linear-oblongate, herbaceous; flowers subsessile; calyx commonly not surpassing the fruit; petals obovate, yellow, becoming orange-yellow with age, 5-6 mm. long; carpels 5, turgid and thin-walled, about 5.5 mm. high, peaked (with dehiscence sharply 2-beaked). *S. cuneifolia* Gray. In saline soils in the Rio Grande Plains and Valley of s. Tex., Apr.-Sept.; also adj. Mex.

This and the following species are extremely close. They may eventually prove to be conspecific.

5. *Sida Helleri* Rose. COPPER SIDA. Suffrutescent, much-branched; branches spreading or procumbent, cinereous, to 3 dm. long or more; leaves suborbicular, crenate, rounded to truncate at the base, to about 16 mm. in diameter, loosely stellate-pubescent on both surfaces; petioles slender, 6-12 mm. long; stipules elliptic-obovate to elliptic; flowers small, subsessile or with pedicels to 4 mm. long, leafy-bracted; sepals ovate-oblong, obtusish, becoming 6 mm. long, surpassing the fruit; corolla pale-copper-colored; carpels 5, obtusely peaked. In sandy or clayey soils of s. coastal Tex., Feb.-May; endemic.

6. *Sida physocalyx* Gray. Plant loosely and coarsely stellate-hirsute, green, partly glabrate; stems spreading or decumbent from a fleshy-ligneous perennial rootstock, to about 4 dm. long; leaves with petioles to 3 cm. long, rather succulent, suborbicular to oblong, obtuse to broadly rounded at apex, cordate at base, to 6 cm. long and 5 cm. wide, crenate or serrate; pedicels solitary in the axils, soon recurved; calyx lobes cordate in appearance, with a small apical ligule, in anthesis about 8 mm. long and pale-green, at length 10-12 mm. long, membranaceous and veiny, together connivent and forming a vesicular globular and wing-angled loose covering over the fruit; petals yellowish or buff-color, scarcely exceeding the calyx; carpels 10 to 14, blackish when mature, ovate with a short beaklike apex, very thin-membranaceous and reticulate-veiny. *S. hastata* St.-Hil. In sandy, gravelly or rocky soils on prairies, in washes and waste ground, mainly in w. two thirds of Tex., May-Oct.; from Tex. to Ariz., s. to S.A.

7. *Sida paniculata* L. Slender erect herb or subshrub, the branches from a woody base and densely stellate-pubescent with coarse appressed fulvous hairs; leaves mostly short-petiolate, rarely with petioles to 6 cm. long, ovate to ovate-lanceolate, mostly densely stellate-pubescent, rounded to cordate at base, obtuse to acuminate at apex, crenate, to about 11 cm. long, usually much smaller; flowers in loose glabrate panicles; pedicels filiform, 2.5-4 cm. long, articulate 2-3 mm. below calyx; calyx nonangulate, 2-3 mm. long, the minute lobes triangular; petals reddish-purple to orange-red, acuminate-apiculate, reflexed at maturity, 3-4 mm. long; carpels 5, not beaked. *S. capillaris* Cav., *S. floribunda* H.B.K. In thickets, open woods and groves in the Rio Grande Plains and Valley, sandy soils, throughout the year; from s. Tex. and the W.I., s. to S.A.

8. *Sida filicaulis* T.&G. Stems branched at base, weak and prostrate-spreading, from a slender woody rootstock, to 5 dm. long or more, stellate-puberulent and with or without long spreading hairs; leaves with slender petioles about as long as the blade, broadly ovate to lanceolate, subtruncate to cordate at base, rounded to bluntly obtuse at apex, stellate-puberulent and sometimes with scattered long hairs, crenate-dentate, to 35 mm. long, usually much smaller; flowers solitary in axils of leaves, with slender pedicels much-exceeding the petioles; calyx somewhat angulate-turbinate, about 5 mm. long; petals orange-yellow or yellow, much-surpassing the calyx; carpels 5, varying from barely apiculate to the dehiscent apex with 2 prominent stout points. *S. diffusa* of auth., *S. procumbens* of auth., *S. filiformis* Moric. On rocky open hills, in sandy or rocky open woodlands, on ledges and in waste areas from n.-cen. to s. Tex., w. to the Trans-Pecos, mostly Mar.-Sept.; from Tex. to Ariz., the W.I. and n. S.A.; also Fla. Keys.

9. *Sida spinosa* L. PRICKLY MALLOW. Annual, finely pubescent, to about 7 dm. high; leaves with petioles to 3 cm. long, ovate to ovate-lanceolate or narrowly lanceolate, to about 55 mm. long and 3 cm. wide, broadly rounded to truncate or subcordate at base, obtuse to subacute at apex, crenate-dentate; stipules linear; petioles of the larger leaves with a small spinelike tubercle at the base dorsally; flowers axillary, with pedicels shorter than the petioles; calyx 5-7 mm. long, the lobes triangular and acute; petals pale-yellow, slightly exceeding the calyx; carpels 5, dehiscent at the apex into 2 prominent beaks. *S. angustifolia* Lam., *S. heterocarpa* Engelm. Mostly in waste lands and disturbed soils in the s. and e. half of Tex., throughout the year; a widespread weedy species mostly in the trop.

10. *Sida filipes* Gray. Subshrub or herbaceous from a perennial rootstock, to about 1 m. high, paniculately branched, rather slender, fulvous-canescens with close stellate pubescence; leaves very short-petioled, lanceolate or the lower ones oblong, coarsely dentate-serrate, obtuse to acute at apex, cordate to truncate at base, 2-7 cm. long, pubescent and dark-green above, canescently stellate-tomentose and pale beneath; pedicels filiform, as long as or longer than the leaves, articulate 3-6 mm. below calyx, the small flower nodding in and after anthesis; calyx lobes about 2 mm. long, ovate, obtuse; petals obovate, deep violet-purple, 4-5 mm. long; carpels 7 or 8, obtusely apiculate at the eventually dehiscent apex, puberulent to glabrate, the sides favose-rugose. In rocky ravines, on dryish limestone hills and flats on the Edwards Plateau and Rio Grande Plains of s. Tex., Mar.-Aug.; also n. Mex.

11. *Sida cordifolia* L. Perennial or somewhat woody annual, densely stellate-velvety-tomentose throughout, to 15 dm. high, the stems erect and rather stout; leaves ovate to ovate-orbicular or ovate-oblong, cordate at base, acute to obtuse at apex, irregularly

crenate-dentate, to 1 dm. long and 5 cm. wide, the lower leaves long-petioled; flowers terminal and axillary, corymbose or subglomerate, with pedicels to 15 mm. long; calyx canescent-tomentose, 5-angled, 6-8 mm. long, the triangular lobes acute; petals yellow or salmon-pink, nearly twice as long as the calyx; carpels 7 to 12, biaristate when dehiscent or merely bimucronate, their sides reticulated. *S. althaeifolia* Sw., *S. hamulosa* Salzm., *S. herbacea* Cav., *S. micans* Cav. Uncommon in sandy soils on plains and along roadsides in the Rio Grande Valley and Trans-Pecos, July-Nov.; from Fla. to Tex., the W.I. and trop. Am.; also Old World trop.

12. *Sida Lindheimeri* Engelm. & Gray. Plant stellately cinereous-puberulent, to about 9 dm. high, the erect or sprawling stems herbaceous from a woody base; leaves with petioles 1 cm. long or less, linear to linear-lanceolate, 1.5-4 cm. long, obtuse to acute at apex, truncate to rounded at base, serrate on the often purplish margins, minutely and densely; stellate-pubescent beneath; pedicels slender, borne mostly in the upper axils, to 5 cm. long, about equaling or frequently exceeding the subtending leaves; calyx 8-10 mm. long, the lobes broadly ovate and acute, the margins often purplish; petals yellow to salmon-color, 12-15 mm. long; carpels about 10, dorsally puberulent or glabrate, cuspidately bidentate. *S. texana* Small. In sandy soils in open woodlands, scrub and thickets, and in beach areas in s. and coastal Tex., Apr.-Oct.; from La. to Mex.

13. *Sida longipes* Gray. Stems herbaceous from a woody rootstock, strictly erect, branched from the base, somewhat scabrous-puberulent, not cinereous, to about 4 dm. high; leaves with petioles to about 25 mm. long, linear-elongate to linear-lanceolate, narrowly obtuse at apex, truncate to broadly cuneate at base, serrulate or crenulate on the often purplish margins, to about 6 cm. long, much-surpassed by the erect elongate pedicels that are to 15 cm. long; calyx about 7 mm. long, the lobes triangular-ovate and acute; petals orange-color, about 15 mm. long; carpels 8 to 10, puberulent to glabrous, muticous or only slightly obtuse. On limestone hills and mt. slopes in the Edwards Plateau and Trans-Pecos, rare in the Rio Grande Plains, Apr.-Sept.; also probably adj. Mex.

14. *Sida rhombifolia* L. AXOCATZIN. Plant herbaceous or shrubby, to about 2 m. high, the stems minutely stellate-pubescent; leaves short-petiolate, varying from rhombic-oblong to ovate-cuneate or oblanceolate, obtuse to rounded or subacute at apex, cuneate to rounded at base and usually minutely cordate at the very base, to 8 cm. long and 4 cm. wide, pale and cinereous-puberulent beneath, green and subglabrous above, serrate or serrulate; stipules setaceous, caducous; pedicels more or less elongated; calyx 5-7 mm. long, minutely cinereous-puberulent, the base (at maturity) with 5 to 10 callous-thickened nerves, the lobes broadly ovate and acuminate; petals pale-yellow to orange-yellow, about 6 mm. long, sometimes red at base; carpels 10, smoothish, subulately 2-awned or merely acute. *S. alba* Cav. In sandy-clayey soils in brushlands, meadows, low open woods and alluvial soils in e. third of Tex., throughout the year; from N.C. to Fla. and Tex.; widespread, mostly in the trop.

15. *Sida tragiaefolia* Gray. Herbaceous perennial to about 6 dm. high, stellar-pubescent or puberulent and with scattered long hairs throughout; leaves with petioles to 15 mm. long, ovate-oblong to linear-oblong, cordate to truncate at base, mostly obtuse at apex to about 5 cm. long, coarsely dentate, stellate-pilose beneath, glabrate above; flowers mostly solitary in the axils, with slender pedicels; calyx 7-8 mm. long, with a somewhat 10-angled base, densely stellate-tomentose and usually profusely adorned with long silvery hairs, the lobes triangular and acuminate; petals orange-yellow, to 14 mm. long; carpels 9 to 12, with thin sides rugose-reticulated below, smooth towards the obtuse bimucronate apex. Uncommon on limestone hills in the Rio Grande Plains and Big Bend region of the Trans-Pecos, May-Nov.; from Tex. to Ariz. and n. Mex.

16. *Sida neomexicana* Gray. Stems usually herbaceous, rather numerous from a woody rootstock, to about 4 dm. high, minutely stellate-pubescent; leaves with petioles 1 cm. long or less, linear-elongate to linear-oblong, to 6 cm. long, obtuse to acute at apex, rounded to truncate at base, serrate on the often purplish margins, finely stellate-pubescent (especially beneath) but green; flowers sessile or with pedicels to about 1 cm. long, borne mainly and somewhat clustered at the ends of the branches; calyx about 8 mm. long, the lobes broadly ovate and subacuminate; petals orange-color, turning purplish or reddish with age, about 1 cm. long; carpels 10, muticous or scarcely bimucronulate. In

rocky soils in mts. and plains of the Trans-Pecos, July-Nov.; from w. Tex. to s. Ariz. and n. Mex.

22. ANODA CAV.

Plants sparsely hirsute to densely puberulent or tomentose; leaves (especially the upper ones) often hastate at base; involucre none; fruit depressed, hemispheric or disklike; carpels usually umbonate or spurred on the back, with fragile lateral walls, these usually breaking up before maturity, the inner layer forming a saclike envelope of the seed or becoming closely adherent to the seedcoat, the dorsal wall more persistent.

About 10 species that are confined to the Western Hemisphere.

1. Fruit hemispheric or somewhat lower but not flat and disklike; carpels puberulent to short-hirsute, rounded to umbonate or angled to short-spurred on the back; calyx more or less conforming with the fruit 1. *A. pentaschista*.
1. Fruit a flattened disk of radiating carpels, these conspicuously long-hirsute to hispid, with an elongated dorsal spur; calyx spreading in fruit (2)
- 2(1). Essentially acaulescent plant to about 5 cm. high; leaves in rosette, ovate 2. *A. pygmaea*.
2. Stem well-developed, typically 30 cm. high or more; leaves scattered on stem, somewhat triangular (3)
- 3(2). Petals purple; herbage sparsely hirsute with long mostly simple spreading or retrorse hairs, sometimes slightly puberulent or glabrate; carpels 9 to 20, hispid, not reticulate on the back; leaves truncate or broadly cuneate at base 3. *A. cristata*.
3. Petals orange-yellow, purplish at base; herbage densely stellately puberulent or short-pilose, a few long simple hairs often also present, the pubescence slightly viscid; carpels 10 to 12, hirsute, strongly reticulate on the back with black veins; lower leaves cordate or subcordate at base 4. *A. Wrightii*.

1. *Anoda pentaschista* Gray. Plant very slender, to about 6 dm. high, paniculately branched, puberulent and more or less cinereous throughout; leaves to 7 cm. long, usually much smaller, pale beneath, the slender-petioled lower ones ovate to subcordate and somewhat 3-lobed, the upper short-petioled leaves hastate to lanceolate or with some linear; flowers with slender pedicels to 25 mm. long that are noticeably articulated above the middle, arranged in panicles; calyx about 4 mm. long, rounded and apiculate, a little shorter than the bright-yellow corolla; carpels usually 5, sometimes 6 to 9, dehiscent dorsal portion closely applied to and half covering the puberulent seed, membranous with an inflexed thickish apex. Incl. var. *obtusior* Robins. In open woods and thickets in the Rio Grande Plains and Valley, and in the Trans-Pecos, Aug.-Dec.; from Tex. to Ariz. and adj. Mex.

2. *Anoda pygmaea* Correll. Plant about 5 cm. high, essentially acaulescent, consisting of a rosette of leaves and one or more pedunculate flowers that are large for the plant, densely covered with stellate hairs; petioles stout, to 3 cm. long; blades thickish, ovate to ovate-elliptic, usually slightly longer than petioles, to about 2 cm. wide, rounded to slightly cordate at base, obtuse at apex, coarsely crenate-serrate, the primary veins prominent; peduncle slender in flower, becoming stout in fruit, to about 2 cm. long; sepals 5, united for about half their length to form a concave disk 2.5-3 cm. wide, the spreading lobes broadly triangular and acute, with simple hairs on the inner surface; petals probably (?) yellowish, obovate-oblongate, about 15 mm. long and 8 mm. wide above middle; fruit a flattened disk of 12 radiating carpels; carpels about 5 mm. long, conspicuously beaked and dorsally spurred, the outer surface stellately pubescent, the sides or partitions coarsely reticulate-honeycombed; seeds reddish-brown, glabrous except for several cilia about the hilum. Definite locality unknown. "Texas, Pope" (Capt. John Pope explored Texas in 1854 from Preston, Grayson Co., on the Red River southwest to El Paso on the Rio Grande.)

3. *Anoda cristata* (L.) Schlecht. Plant branched from near base, erect, to about 8 dm. high, sparsely hirsute with mostly simple hairs; leaves petiolate, deltoid to triangular-

ovate or -lanceolate, truncate to broadly cuneate at base, acute to acuminate at apex, occasionally hastate or subtrilobate at the base, the margins either irregularly dentate or entire; flowers solitary on long peduncles in the axils; calyx with triangular-lanceolate acuminate spreading lobes to 15 mm. long, often purplish-red; petals purple, commonly cuneiform and retuse, 1-2.5 cm. long; carpels 15 to 20, rather conspicuously beaked, hispid, the dorso-basal portion wholly thin-scarious and veinless and with slender mid-nerve, the sides or partitions wholly obliterated in the breaking up of the fruit; seeds naked, puberulent. *A. lavaterioides* Medic., *A. hastata* of auth. On gravelly banks and in open woods along streams in the Trans-Pecos, July-Nov.; from Tex. to Ariz., s. to S.A.

The leaves of this species are exceedingly variable, even upon the same individual. Our plant usually has the upper leaves elongated and conspicuously hastate.

4. *Anoda Wrightii* Gray. Plant erect, to 15 dm. high, viscidulous-puberulent and above more or less villous-hirsute; lower leaves deltoid-ovate, the upper ones hastate-lanceolate; peduncles about equaling or exceeding the subtending leaves, or the upper ones in a naked raceme and subtended by linear or filiform deciduous bracts; calyx canescently pubescent; petals dull-yellow, 1-1.3 cm. long, changing to brown-purple at base; carpels 10 to 12, beaked, the dorsal portion bilamellar at maturity, the tardily separable endocarpial layer of firm texture, clathrate-reticulate, loosely half-enveloping the minutely or sparsely puberulent seed. Rare in shrubby growth in the Trans-Pecos, July-Sept.; from Tex. to Ariz. and adj. Mex.

FAM. 116. STERCULIACEAE BARTL.

CACAO FAMILY

Trees, shrubs or herbs, sometimes scandent, the pubescence chiefly of stellate hairs; leaves alternate, simple or rarely compound, usually stipulate; flowers large or small, mostly in axillary cymes, perfect or unisexual, regular or sometimes irregular; calyx persistent, gamosepalous, usually 5-parted; petals 5 or none, hypogynous, free or united with the stamen tube; stamens 5, connate at least at the base, the tube commonly with 5 staminodia, the 2- or 3-celled anthers borne in the sinuses; fruit dry or rarely baccate, usually 5-celled, variously dehiscent.

About 700 species in 60 genera, mainly tropical and Old World. The seeds of the important tropical American tree, *Theobroma cacao* L., are the source of cocoa and chocolate. The Chinese parasol-tree, *Firmiana simplex* W. Wight, is cultivated in central and south Texas, but it apparently does not occur as an escape.

1. Petals concave or cucullate (2)

1. Petals flat (3)

2(1). Petals mostly rhomboidal, united at the apex with the stamen tube, with or without a dorsal gland1. *Ayenia*, p. 1055.

2. Petals reniform, free from the stamen tube, without a dorsal gland
.....2. *Nephropetalum*, p. 1057.

3(1). Fruit with numerous pubescent processes; seeds numerous in each cell
.....3. *Hermannia*, p. 1057.

3. Fruit without pubescent processes; seeds 2 in each cell or (by abortion) only one (4)

4(3). Capsule 1-celled, 2.5-3 mm. long4. *Waltheria*, p. 1058.

4. Capsule 5-celled, 4-9 mm. long5. *Melochia*, p. 1058.

1. AYENIA L.¹³⁰

Shrubs or herbs; leaves simple, serrate, crenate or dentate; flowers small, perfect, long-pedicellate, axillary, solitary, fasciculate or in cymes or umbels; calyx 5-lobate; petals 5, with slender claws, cucullate, the apex inflexed and adnate to the stamen tube, often with an elongate gland; stamens 5, alternating with staminodes; anthers 2- or 3-celled, solitary

¹³⁰ Adapted from Carmen L. Cristóbal in *Opera Lilloana IV* (Argentina): 1-230. 1960.

in the sinuses of the stamen tube; fruit a 5-celled warty or spinescent globose capsule that separates into five 1-seeded bivalvate carpels.

About 70 species in warmer regions of America.

1. Flowers 2 or more on a common peduncle from leaf axils; some of the leaves to 35 mm. wide; localized in Brownsville region1. *A. limitaris*.
1. Flowers borne singly or in fascicles in leaf axils; leaves rarely more than 15 mm. wide; apparently usually north of the Brownsville region (2)
- 2(1). Stems stiffly erect; flowers mostly in fascicles; leaf blades typically lanceolate, often narrowly so; fruit on slender stipe 2-3 mm. long or sometimes more; petals with an appendage on the inner face2. *A. filiformis*.
2. Stems with spreading branches; flowers usually solitary or as many as 3; leaf blades typically broadly ovate to ovate-elliptic; fruit on stout stipe about 1.5 mm. long or less; petals with or without an appendage on the inner face (3)
- 3(2). Blade of petals notched at apex and with a somewhat clavellate appendage on the upper part of the inner surface and 2 teeth on the lower part; leaves typically ovate-elliptic, their lower surface sparsely coarsely pubescent with simple or once-branched hairs, rarely subglabrous or with scattered stellate hairs3. *A. pilosa*.
3. Blade of petals not notched and without an appendage or teeth; leaves typically suborbicular-ovate, their lower surface felty with a dense covering of short stellate hairs4. *A. microphylla*.

1. *Ayenia limitaris* Cristóbal. Shrub to about 15 dm. high, with hoary young branches; stipules 4-5 mm. long, subulate, pubescent; leaves with pubescent petioles to about 25 mm. long, ovate, to about 75 mm. long and 35 mm. wide, subacute to subacuminate at apex, rounded to more or less cordate at base, irregularly dentate to dentate-crenate on margins, lightly pubescent above, with long silvery-stellate hairs below but the epidermis not entirely covered; peduncles 1 to 4 at each node, axillary, about 1 cm. long, each supporting 3 flowers; pedicels 3-7 mm. long, pubescent; sepals about 3 mm. long and 1 mm. wide, oval-lanceolate, pubescent; petal with claw 2.5 mm. long, the lamina 1 mm. long and 1.5 mm. wide, lobules rounded with the margins nearly entire; stamen tube 1 mm. long, the external border of the staminodes with a small orifice at each side; style and stigma 0.5 mm. long, the stigma exerted with the lobules slightly notched; fruit 8 mm. long, covered with very short hairs, the prickles 1 mm. long and uniformly pubescent; seeds 4-5 mm. long, wrinkled, tuberculate. *A. Berlandieri* of auth. In clay soil on the edge of thickets and in chaparral in the Brownsville region in the Rio Grande Valley, throughout the year; also Coah.

2. *Ayenia filiformis* Wats. Subshrub to 9 dm. high, erect, very much branched from base, the woody stem to 2 cm. thick, the branches covered with short appressed hairs; stipules subulate, 3-5 mm. long, pubescent; leaves with petioles 5 (to 15) mm. long, orbicular to oval on lower part of branches and to 35 mm. long and 5-18 mm. wide, ovate-lanceolate to lanceolate toward end of branches and 25-55 mm. long and 5-10 mm. wide, rounded at base, subacute at apex, the margins serrated, pubescent with short hairs; the compact inflorescence composed of about 11 rose-color or red flowers; pedicels 3-4 mm. long; sepals 2-3 mm. long, 1-1.5 mm. wide, oval-lanceolate, pubescent; petal with claw 3-6 mm. long, subtriangular to rhomboidal, 1-2 mm. long, 1-2.5 mm. wide, the posterior side concave, straight or convex, the outer surface pubescent, appendage about one third as long as lamina; stamen tube 1 mm. long, free portion of filaments reaching middle of tube, the internal margin of the staminode not reaching the style; style 0.5 mm. long, partially exerted; stigma with small globose lobes; fruit 3-4 mm. long, densely pubescent, the prickles 0.5 mm. long; seed 2.5-3 mm. long, tuberculate. On limestone and granite soils on hills, bluffs and in canyons in mts. of the Trans-Pecos, May-Dec.; from Tex. to Ariz. and n. Mex.

3. *Ayenia pilosa* Cristóbal, Subshrub, decumbent, 1-2 dm. high, very much branched from the base, the branches covered with appressed hairs; stipules 0.5-1 mm. long, pubescent, subulate; petiole 5 (to 10) mm. long, pubescent; leaf blade 15 (to 30) mm. long, 8 (to 10) mm. wide, orbicular on lower part of branches, ovate-elliptic to suborbicular

toward end of branches, the margin dentate to dentate-crenate, mostly adorned with long branched or simple hairs; flowers 2 or 3 in axils, reddish, with pubescent pedicels 1.5-2 mm. long; sepals oval, pubescent, about 2 mm. long and 1 mm. wide; petal with claw 4 mm. long, rhomboidal, about 1 mm. long and wide, with the upper side somewhat concave, the outer surface lightly pubescent, the appendage about half as long as the lamina, the lower teeth a little larger than the upper ones; stamen tube 1 mm. long, the free portion of filaments reaching to middle of tube; internal margin of staminodes not reaching the style; style 0.5 mm. long, partially exerted; stigma with small globose lobules; fruit 3-3.5 mm. long, covered with hairs, the prickles 0.5 mm. long; seeds 2-2.5 mm. long, lightly tuberculate, irregularly wrinkled. *A. pusilla* of auth. In rocky soils or sandy loam in mesquite-chaparral, on slopes and about rimrock in Rio Grande Plains, w. Edwards Plateau and Trans-Pecos, throughout most of year; from Tex. and N.M., s. to S.L.P. and Tam.

4. *Ayenia microphylla* Gray. Erect or spreading shrub to 6 dm. high; stem woody, to 17 mm. thick, the principal axis branched from the ground; young branches gray, with short appressed hairs; stipules 1.5-2.5 mm. long, subulate, persistent, pubescent; petiole to 12 mm. long, usually much shorter, hoary; leaf blade orbicular to suborbicular on lower part of stem, ovate on upper part, to 3 cm. long and 18 mm. wide, usually about 12 mm. long and 7 mm. wide, subacute at apex, marginally serrated, the nerves prominent, the lower surface (especially in young leaves) densely hoary-felty beneath with short stellate hairs; 1 or 2 flowers in axils, on pubescent pedicels about 4 mm. long; sepals 3 mm. long, 1.5 mm. wide, oval-lanceolate, stellately pubescent; stamen tube 1 mm. long, campanulate, lobed for one third its length, cucullate, the external margin waved, apiculate; filaments free at apex; style 5 mm. long, scarcely exerted; stigma capitate, globular, the lobes small; fruit 5 mm. long, pendulous, hoary, prickles 0.5 mm. long, obscure, pubescent; seed 3 mm. long, wrinkled, with small scattered tubercles. Among boulders and on limestone hills and slopes of arroyos in the Trans-Pecos and w. Edwards Plateau, throughout most of the year; from Tex. to Ariz. and Coah.

2. NEPHROPETALUM ROBINS. & GREENM.

A monotypic genus.

1. *Nephropetalum Pringlei* Robins. & Greenm. Stellate-tomentose unarmed shrub; stem terete, nearly glabrate; leaves simple, alternate, ovate, cordate with a narrow sinus, acuminate to an obtusish apex, crenate-dentate, palmately 7-nerved from the base, finely stellate-pubescent above, paler and tomentulose beneath, 9-12.5 cm. long, 4-7.5 cm. wide; petioles canescent-tomentulose, about 4 cm. long; stipules setaceous, deciduous, nearly 4 mm. long; axillary umbelliform cymes 2- or 3-flowered, about 25 mm. long, the peduncles about equaling the pedicels; flowers greenish, only about 2 mm. in diameter; calyx deeply 5-parted, the segments ovate; petals 5, unguiculate, slightly adnate at base to the staminal cup, free at the apex, the blade reniform with a deep sinus at the attachment of the claw, concave and neither appendaged nor glandular; stamens 5, united into a short cup; anthers 3-locular, sessile or nearly so, extrorse, the cells parallel and longitudinally dehiscent; staminodes 5, alternate with the stamens and opposite the sepals, rounded and cucullate at the summit; ovary sessile, globose, 5-celled; ovules 2 in each ovary-cell, superposed on axial placentae; style short, terete; stigma capitate; young fruit globose, covered with numerous pubescent processes; seeds by abortion solitary in the cells. Known only from Hidalgo Co. where it was collected once in August 1888; to be expected elsewhere in Tex. and in Tam.

3. HERMANNIA L.

About 300 species, mainly African.

1. *Hermannia texana* Gray. Plant suffrutescent or with herbaceous stems from a woody rootstock, to about 5 dm. high, more or less densely stellate-pubescent throughout; leaves thick-herbaceous, with petioles to 2 cm. long, suborbicular to broadly ovate-elliptic, mostly broadly rounded at apex, rounded to truncate or cordate at base, to about 6 cm.

wide, dentate to sinuate-dentate; flowers perfect, axillary, pendulous, 5-merous, several in a cyme, the peduncles to about 25 mm. long to exceed the recurved pedicels; calyx lobes triangular-lanceolate, acuminate, to 5 mm. long; petals deep-orange-yellow to orange-red, erect, persistent, 8-12 mm. long, the long claw with inrolled edges, the blade obliquely suborbicular, pandurate when spread out; stamens 5, connate below the middle to form a tube; anthers linear, about 3.5 mm. long, pubescent; capsule subglobose to oblong-quadrate, loculicidally 5-valvate, covered with hairy filiform processes to 3.5 mm. long; seeds several in each cell, dark-brown or blackish, crescentiform, pitted. In dry rocky calcareous or gypseous soils on slopes and prairies, in red sands, and rarely on the edge of salt marshes and on dunes along the coast from s. Edwards Plateau to the coast in Tex., Apr.-Nov.; also adj. Mex.

4. WALTHERIA L.

About 50 species widely distributed in the warmer regions of the world, mainly tropical America.

1. *Waltheria indica* L. *HIERBA DEL SOLDADO*. Shrub or somewhat herbaceous, from a woody rootstock, to about 2 m. high, more or less stellately velvety-tomentose throughout, erect or the branches sometimes decumbent; leaves with a petiole to 2 cm. long, broadly ovate to oblong-elliptic, obtuse to rounded at apex, rounded to subcordate at base, to 8 cm. long, crenate-dentate; flowers fragrant, perfect, 5-merous, in sessile or pedunculate glomerules to 1 cm. long; calyx strongly ribbed, the triangular-lanceolate acuminate lobes about as long as the tube; petals yellow, spatulate, obtuse, 4-6 mm. long, persistent in fruit, usually slightly longer than the calyx; stamens 5, the filaments more or less connate; anthers about 1 mm. long; style bearded; capsule obliquely globose, pubescent, 2.5-3 mm. long, 1-seeded. *W. americana* L. In rocky or sandy soil in extreme s. Tex., winter and spring; from s. Fla., s. Tex. and s. Ariz., s. throughout trop. Am.

5. MELOCHIA L.* BROOM-WOOD

Shrubs or herbs, with pubescence of simple or stellate hairs; leaves dentate; flowers mostly small, in cymes or dense axillary glomerules; involucrel present or wanting; calyx 5-lobate; petals 5, spatulate, marcescent; stamens 5, the filaments connate at the base or higher; capsule 5-celled, loculicidally 5-valvate, the cells 1-seeded; carpels easily separating, sometimes indehiscent.

About 75 species in warm regions of both hemispheres.

1. Involucrel of 3 or more bractlets; capsule subglobose, scarcely beaked, 5 mm. or less wide 1. *M. corchorifolia*.
1. Involucrel wanting; capsule angular or pyramidal, long-beaked, much more than 5 mm. wide (2)
- 2(1). Leaves glabrous or nearly so, green; capsule glabrous or glabrate, with sharp acute angles, short-stipitate 2. *M. pyramidata*.
2. Leaves densely stellate-tomentose, usually whitish beneath; capsule densely pubescent, with somewhat rounded angles, on a relatively long stipe 3. *M. tomentosa*.

1. *Melochia corchorifolia* L. Stem to 15 dm. high, glabrous or sparingly pubescent, virgately branched; leaves with petioles to about 2 cm. long, ovate to ovate-lanceolate, to 6 cm. long and 3 cm. wide, irregularly serrate and sometimes lobate, usually entirely glabrous; flowers cluster dense; calyx lobes acute; petals purple or with the claw yellowish, 4-7 mm. long; capsule subglobose, strigose with simple hairs, 4-4.5 mm. in diameter. Old fields, cult. grounds and waste places in s.e. Tex., Aug.-Oct.; from Fla. to Tex. and S.C., s. to Braz.; also Old World tropics, where native.

2. *Melochia pyramidata* L. Slender shrub to 2 m. high, often herbaceous, lightly pubescent to glabrate throughout; leaves with slender petioles to 12 mm. long, rounded-ovate to lanceolate, obtuse to short-acuminate at apex, rounded to broadly cuneate at base, to 35 mm. long and 2 cm. wide, serrate, thin, green, glabrous or frequently sparsely

* Cf. Aaron Goldberg in *Contr. U. S. Nat. Herb.* 34: 191-363. 1967.

pubescent; flowers solitary or in axillary cymes, mostly pedicellate; calyx lobes long-acuminate; petals pink or violet, about 7 mm. long; capsule broadly triangular in outline, glabrate or sparsely puberulent, 5-6 mm. long and somewhat broader, the lobes truncate or broadly rounded at base, acute and spreading; seeds dull-brown to black. In sandy or rocky soil in mesquite thickets, palm groves, dry stream beds, ditches and waste places in the Edwards Plateau and Trans-Pecos, s. to the coast in Tex., Apr.-Nov.; widely distributed in the warmer regions of both hemispheres. We have only var. *pyramidata*.

3. *Melochia tomentosa* L. Shrub to 2 m. high, the branches herbaceous, more or less pale stellate-tomentose throughout; leaves with petioles to 25 mm. long, broadly rhombic-ovate to elliptic-lanceolate or oblong-elliptic, rounded to acute at apex, rounded to subcordate at base, to 7 cm. long and 4 cm. wide, crenate or dentate, thick, usually densely and finely tomentose on both surfaces; flowers in loose cymes, mostly pedicellate; calyx lobes lanceolate to linear-lanceolate, acuminate, pubescent; petals pink to violet, to 15 mm. long; capsule rhombic in outline, stellate-tomentose, 6-9 mm. long, long-beaked, the lobes rounded to acutish at base. In open woodlands and brushlands in s. Fla. and s. Tex., summer-fall; widely distributed in the warmer parts of the W. Hemis.

We have only var. *tomentosa*.

FAM. 117. THEACEAE D. DON

CAMELLIA FAMILY

Shrubs or small trees with simple alternate exstipulate deciduous leaves; flowers perfect, showy, borne singly in the axils of leaves; sepals 5 or rarely 6, somewhat unequal, persistent, subtended by one or more caducous bracteoles; petals 5 or rarely as many as 8, white, imbricate, silky pubescent on the outer surface, the outermost ones usually smallest and somewhat concave, connate at base; stamens numerous, the filaments united at their base and adnate to base of corolla; styles 5, distinct or united; ovary 5-celled, superior; capsule globose to ovoid, loculicidally dehiscent, woody, pubescent; seeds 1 to 4, compressed.

Several hundred species in about 25 genera mainly in the tropics of both hemispheres.

1. STEWARTIA L.

WILD-CAMELLIA. STEWARTIA

Characters of the family. A genus of about 10 species in eastern Asia and southern United States.

1. *Stewartia Malacodendron* L. SILKY CAMELLIA. Shrub or small tree to 6 m. tall; leaves shortly petioled, ovate to elliptic or somewhat obovate, cuneate at base, acute to shortly acuminate at apex, to 1 dm. long, the margins serrulate and ciliate, the lower surface light green and pubescent; sepals ovate, about 1 cm. long; petals white, obovate, spreading, 2.5-5 cm. long, the margins somewhat crimped; stamens with dark purple filaments and bluish anthers; styles united as one, stout, the stigma 5-toothed; capsule globular-depressed, beakless, about 15 mm. thick; seeds lustrous, angled but wingless. On wooded banks, hillsides and along streams in e. Tex., Apr.-May; from w. Fla. to La. and Tex., n. to Va., Tenn. and Ark.

FAM. 118. HYPERICACEAE JUSS.

ST. JOHN'S-WORT FAMILY

Herbs or shrubs; leaves with or without a basal articulation, opposite, entire, glandular-dotted as seen under a lens with transmitted light, mostly sessile, exstipulate; flowers perfect, usually regular and hypogynous; sepals 4 or 5, imbricated in the bud, herbaceous, with or without a basal articulation, persistent; petals 4 or 5, mostly deciduous, oblique and mostly convolute in the bud; stamens many or few, sometimes grouped in 3 or more clusters or bundles; capsule 1-celled, with 2 to 5 parietal placentae and as many usually persistent styles, sometimes 3- to 7-celled by the union of the placentae in the center, mostly septicidally dehiscent; seeds numerous, usually areolate or reticulate.

Approximately 1,000 species in about 50 genera, primarily tropical in distribution.

1. Sepals 4, in 2 very unequal pairs; petals 4; stamens many, distinct 1. *Ascyrum*, p. 1060.
 1. Sepals 5; petals 5; stamens many to few, often in 3 to 5 clusters 2. *Hypericum*, p. 1061.

1. ASCYRUM L.

ST. PETER'S-WORT

Low smooth pale essentially evergreen shrubs; stems simple or sparsely branched, when young 2-edged or winged; leaves usually numerous, small; flowers solitary or in small cymules, pedicellate, each subtended by a pair of bractlets; sepals 4, herbaceous, the 2 outer ones broad and leaflike, compressed and persistent, the 2 inner ones usually much smaller; petals 4, pale-yellow, oblique, fugacious, cruciate, spreading, convolute in the bud; stamens numerous, the filaments distinct and not noticeably in clusters, marcescent; capsule 1-celled, ovoid, 2- to 4-valved, enclosed by the sepals; seeds numerous, black, reticulate.

Five species, mainly in southeastern United States; merged with *Hypericum* by some authors.

1. Styles 3 or 4; inner sepals only slightly smaller than the outer ones that are to 2 cm. long and 15 mm. wide; leaves oblong-elliptic, the upper ones somewhat cordate and clasping 1. *A. stans*.
 1. Styles 2; inner sepals minute or obsolete; leaves mostly linear- to oblong-oblancoelate, narrowed at base 2. *A. hypericoides*.

1. *Ascyrum stans* Michx. ST. PETER'S-WORT. Plant with stems erect or suberect, mostly 3-8 dm. high; leaves oblong-elliptic, rounded to somewhat acute at apex, the upper ones somewhat cordate and clasping, coriaceous, to about 3 cm. long and 15 mm. wide; pedicels to 1 cm. long, with lanceolate bractlets 3-5 mm. below the calyx; outer 2 sepals broadly ovate to suborbicular, cordate at base, acute at apex, 1-1.5 cm. long, about as wide; inner 2 sepals lanceolate, 7-14 mm. long, to 4 mm. wide; petals showy, obliquely obovate, commonly exceeding the sepals, to 15 mm. wide; styles 3 or 4; capsule exerted at maturity. *Hypericum stans* (Michx.) Adams & Robson. In sandy bogs, swamp woods and moist grasslands in e. Tex., June-Sept.; from Fla. to Tex., n. to N.Y., N.J., e. Pa., Ky., Tenn., Ark. and Okla.

2. *Ascyrum hypericoides* L. ST. ANDREW'S CROSS. Plant with reddish-brown stems that are erect-ascending to decumbent and somewhat diffuse, simple or more or less branched from the base or above the base, to 1 m. or more high or long, the bark exfoliating in shreds; leaves linear to oblanceolate, more or less narrowed at the sessile base, rounded to obtuse at apex, to about 3 cm. long and 8 mm. wide, the margin somewhat revolute; pedicels 3-6 mm. long, the bractlets borne near apex; outer 2 sepals ovate to elliptic, rounded-cuneate to subcordate at base, obtuse to acute at apex, to 12 mm. long and about as wide; inner 2 sepals minute or obsolete; petals narrowly oblong-elliptic, about equaling the outer sepals, to 4 mm. wide; styles 2; capsule included or exerted at maturity. *Hypericum hypericoides* (L.) Crantz. Mostly in light sandy soils in open pine-hardwood and hardwood forests, thickets, grasslands and in bogs in the e. third of Tex., May-Nov.; from Fla. to Tex. and e. Mex., s. to Hond. and the W.I., n. to N.E., Ky., Mo. and Okla.

This species is highly variable in the size and shape of its leaves and outer calyx lobes, and some of our coastal material might eventually be segregated as a small narrow-leaved variant. Not only decumbent plants with several basal stems and oblanceolate leaves, segregated as var. *multicaule* (Michx.) Fern. [*Hypericum hypericoides* var. *multicaule* (Michx.) Fosb.], are to be found in Texas but also the erect plant, segregated as var. *oblongifolium* (Spach) Fern., with rather broadly oblanceolate leaves and prominent basally cordate outer calyx lobes that are up to 15 mm. long and 1 cm. wide. Var. *hypericoides*, our most common plant, is erect and freely branched above the ground level and has linear to linear-elliptic leaves.

2. HYPERICUM L.¹³¹

ST. JOHN'S-WORT

Herbs or shrubs; leaves opposite, sometimes verticillate; flowers solitary or in cymes; sepals 5, usually subequal, persistent; petals 5, oblique, usually convolute in the bud, yellow, flesh-colored or sometimes reddish or purplish; stamens usually numerous, mostly united or clustered in 3 to 5 fascicles, the filaments elongate; styles abbreviated or elongate, separate or (at first) connate for most or part of their lengths, more or less united below the middle, mostly persistent on the capsules, the stigmas minute or capitate; capsules mostly 1-celled or sometimes 3- to 5-celled; seeds short-cylindric, mostly reticulate.

About 300 species that are cosmopolitan in their distribution.

1. Stems woody throughout or at least on lower part; styles typically closely appressed their entire length at maturity, the stigmas minute; translucent or pellucid-punctate glands present (2)
1. Stems herbaceous or rarely slightly woody at very base; styles either appressed or separate (11)
- 2(1). Mature leaves and sepals linear-subulate or needlelike, the leaf margins essentially parallel 7. *H. fasciculatum*.
2. Mature leaves and sepals with expanded non-needlelike blades, the leaves somewhat wider above the middle (3)
- 3(2). Flowers terminal and solitary, sometimes in 3-flowered dichasia 5. *H. frondosum*.
3. Flowers in a 3- to many-flowered terminal and/or subterminal dichasia (4)
- 4(3). Perennial herb, usually less than 1 m. tall 11. *H. sphaerocarpon*.
4. Shrubs; stems mostly 1 m. or more tall (5)
- 5(4). Leaves and sepals without a basal articulation or groove; inflorescence appearing naked due to the much-reduced bracts (6)
5. Leaves and sepals with a basal articulation or groove; inflorescence appearing leafy due to the foliaceous bracts (8)
- 6(5). Leaves linear-oblong to linear-lanceolate, less than 1 cm. wide, midnerve beneath prominently keeled and running into a stem wing ... 10. *H. cistifolium*.
6. Leaves ovate-lanceolate to elliptic, usually well over 1 cm. wide (7)
- 7(6). Inflorescence usually a many-flowered (rarely 3) dichasium; mature capsules 3.5-7 mm. long, 3-4.5 mm. wide; raphe of seed well-developed, forming a conspicuous keel 8. *H. nudiflorum*.
7. Inflorescence a 3-flowered dichasium, sometimes 6- or 1-flowered; mature capsules 6-14 mm. long, 4.5-7 mm. wide; raphe of seeds only slightly developed, forming a low ridge but not a conspicuous keel 9. *H. apocynifolium*.
- 8(5). Largest leaves 1.5-3 cm. long; seeds 0.7-0.8 mm. long 6. *H. galioides*.
8. Largest leaves 3-7.5 cm. long; seeds 0.9-1.6 mm. long (9)
- 9(8). Mature capsules exceeding 7 mm. in length and 3.5 mm. in width, lance-ovoid; flowers in 1- to 7-flowered terminal and subterminal dichasia, the inflorescence usually narrow and compactly thyrsoid; seeds dark-brown or black, 1-1.7 mm. long 4. *H. prolificum*.
9. Mature capsules 6 mm. or less long and 3 mm. wide, slender-conic; flowers in 7- to many-flowered terminal and subterminal compound dichasia, the inflorescence presenting an obpyramidal aspect; seeds reddish-brown, 0.8-1.3 mm. long (10)

¹³¹ Adapted mainly from William P. Adams in Contr. Gray Herb. 189:3-51. 1962.

- 10(9). All flowers with only 3 styles present 3. *H. densiflorum* var. *densiflorum*.
10. Some flowers with 4 or 5 styles present 3. *H. densiflorum* var. *lobocarpum*.
- 11(1). Petals yellow or orange-color, convolute in bud; stamens numerous or few, distinct or united at base into 3 to 5 clusters without intervening glands; flowers terminal or in terminal cymes (12)
11. Petals flesh-color to mauve-purple, imbricated in bud; stamens mostly 9, strongly triadelphous, with 3 large orange glands alternating with the 3 bundles of stamens; flowers clustered in the axils and at summit of stem (19)
- 12(11). Stamens numerous, usually 20 or more; roots perennial (13)
12. Stamens usually less than 20; annuals or rarely perennials (15)
- 13(12). Stems and leaves copiously pilose; sepals ciliate; petals clear yellow 12. *H. setosum*.
13. Stems and leaves glabrous; sepals glabrous; petals streaked with dark lines (14)
- 14(13). Main stem mostly simple, with branches only near summit; sepals 2.5-4 mm. long; petals 4-7.5 mm. long; styles 2-4 mm. long, mostly persistent 1. *H. punctatum*.
14. Main stem mostly with small axillary branches throughout; sepals 4-7 mm. long; petals 8-14 mm. long; styles 6-10 mm. long, fugacious or seldom persistent 2. *H. pseudomaculatum*.
- 15(12). Leaves flat, varying from suborbicular-ovate to linear-lanceolate, spreading; stem simple or loosely branched, from a slightly woody base (16)
15. Leaves subulate or subulate-linear, appressed or strongly ascending; stem fastigate-branched; root annual (18)
- 16(15). Leaves linear-lanceolate, all sessile and clasping the stem; styles 3 mm. long, the stigma conspicuously capitate 15. *H. pauciflorum*.
16. Leaves orbicular to ovate-deltoid or elliptic-oblong, the upper ones cordate at base or clasping; styles 1 mm. or less long, the stigmas minute (17)
- 17(16). Diffusely branched; leaves ovate-oblong to shortly elliptic, rounded at apex; capsule short-ellipsoid 13. *H. mutilum*.
17. Simple or nearly so, virgate, the cymes with ascending branches; middle and upper leaves ovate-deltoid, tapering to apex; capsule slender-conical 14. *H. gymnanthum*.
- 18(15). Leaves linear, 6 mm. or more long; capsules ovoid, slightly exceeding calyx 16. *H. Drummondii*.
18. Leaves scalelike, less than 4 mm. long; capsules lance-subulate, much-exceeding the calyx 17. *H. gentianoides*.
- 19(11). Leaves tapering below middle to a distinctly slender petiole 19. *H. Walteri*.
19. Leaves sessile at the rounded to cordate-clasping base (20)
- 20(19). Leaves with translucent glands and dark-punctate on lower surface; styles 2-3 mm. long 18. *H. virginicum*.
20. Leaves without translucent glands or superficial dots on lower surface; styles 1 mm. long 20. *H. tubulosum*.

1. *Hypericum punctatum* Lam. Plant erect, to about 1 m. high, conspicuously marked with black and pellucid dots, the main stems mostly simple and with few to no branches below the inflorescence; leaves sessile or somewhat clasping at the base, typically oblong to oblong-elliptic but sometimes narrowly ovate-oblong, to 7 cm. long and 2 cm. wide, rounded to obtuse or even retuse at apex; flowers crowded in small clusters that terminate short branches at summit of plant; sepals heavily dotted and lined with black, ovate-oblong to triangular-lanceolate, obtuse to subacute at apex, 2.5-4 mm. long; petals pale yellow, copiously black-dotted, 4-7.5 mm. long; styles 2-4 mm. long, mostly persistent;

capsules ovoid, 4-6 mm. long, conspicuously beset with amber-colored glands; seeds less than 1 mm. long. On open-wooded hills and on edge of woods and fields in n.-cen. and n.e. Tex., June-July; from Fla. to Tex., n. to Que. and Minn.

2. *Hypericum pseudomaculatum* Bush. Plant erect, to 8 dm. high, the main stems mostly with small axillary branches throughout; leaves closely sessile and somewhat clasping at base, ovate-lanceolate to triangular-lanceolate or linear-lanceolate, narrowly obtuse to acute at apex, the margins often revolute in drying, to about 4 cm. long and 12 mm. wide; flowers numerous, in terminal clusters that are more open than in *H. punctatum*; sepals lanceolate, acute to acuminate, 4-7 mm. long, conspicuously black-dotted; petals 8-14 mm. long, conspicuously black-dotted; styles 6-10 mm. long, fugacious or seldom persistent; capsules 5-7 mm. long, somewhat glandular. *H. punctatum* var. *pseudomaculatum* (Bush) Fern. In moist or dry soil in fields in e. Tex., May-June; from Fla. to Tex., n. to Okla. and Ill.

3. *Hypericum densiflorum* Pursh. Shrub to 2 m. high, much-branched above, the upright branches slender; leaves linear to linear-elliptic or oblanceolate, obtuse-apiculate to acute at apex, tapering at base to a short petiole, to 75 mm. long and 15 mm. wide, with smaller leaves in axillary fascicles; flowers numerous in crowded compound cymes; sepals firm, linear-lanceolate to elliptic, 2-5 mm. long; styles 3 to 5, persistent, somewhat connate at base, either completely separate from the beginning or tardily separating, 2-3 mm. long; capsules lance-ovoid to slender-conic, more or less deeply lobed or sulcate, the body to 6 mm. long and 3 mm. thick, composed of 3 to 5 distinct carpels; seeds reddish-brown, 0.8-1.3 mm. long. On pinewood slopes and in and on the edge of swamps and marshes, and along wooded streams, in s.e. Tex., May-Aug.; from Fla. to Tex., n. to N.Y., N.J., W.Va., s. Ind. and s. Mo.

The usually 4 or 5 styles and the deeply lobed capsules of the more southern var. *lobocarpum* (Gatt.) Svens. (*H. lobocarpum* Gatt.) set it apart from var. *densiflorum* and *H. prolificum*. The leaves are also usually larger than those of var. *densiflorum* whose leaves are usually less than 5 cm. long and 8 mm. wide. In our material, where there is a preponderance of flowers with 4 or 5 styles these are early separated in flower. However, in var. *densiflorum* and in those plants having only a few flowers with 4 or 5 styles, the styles often remain tightly coherent or even twisted together until the fruit is well-developed.

4. *Hypericum prolificum* L. SHRUBBY ST. JOHN'S-WORT. Rather coarse diffusely branched shrub to 2 m. high, with sharply 2-edged twigs; leaves typically narrowly oblong, 3-7.5 cm. long and to 15 mm. wide, narrowed at base to a short petiole, obtuse at apex; cymes both terminal and in the upper axils, contracted, the inflorescence thus interruptedly cylindrical; sepals elliptic, 5-7 mm. long; petals obovate, 7-10 mm. long; styles 3 (rarely 4); capsules lance-ovoid to subcylindric-conic, 3-carpellate, 8-15 mm. long, 3-5 mm. thick. *H. spathulatum* (Spach) Steud. In dry or damp sandy or rocky thickets, along wooded streams and on slopes in s.e. Tex., June-Aug.; from Ga. to Tex. and Ark., n. to s.e. N.Y., Ont. and Minn.

5. *Hypericum frondosum* Michx. GOLDEN ST. JOHN'S-WORT. Shrub to 1 m. high, widely branching; leaves narrowly oblong to elliptic, narrowed at base, obtuse to acute at apex, to 75 mm. long and 18 mm. wide; flowers large and showy, 1 to 3 terminating the branches or in the upper axils; sepals foliaceous, very unequal, often enclosing the capsule, some of them ovate to broadly elliptic and 2-3 cm. long; petals orange-yellow, firm, to 2 cm. long, becoming reflexed; stamens very numerous; capsules narrowly conic-ovoid, thick-walled, unlobed, about 1 cm. long. In barrens and openings in e. Tex., Apr.-July; from Ala. to Tex., n. to S.C., Ky. and s. Ind.

An ornamental shrub that is frequently cultivated, from which it has a tendency to escape.

6. *Hypericum galioides* Lam. Shrub 3-18 dm. high; leaves narrowly linear to linear-oblanceolate, narrowed to the base, obtuse to acute at apex, to 3 cm. long and 5 mm. wide, usually noticeably verticillate and marginally revolute in drying; flowers numerous, terminal or axillary; sepals linear to linear-spatulate, 3-4 mm. long; petals bright-yellow, narrowly cuneate, obliquely or almost laterally pointed, 4-7 mm. long; capsules triangular-conic, subtruncate-rounded at base, tapering to the acute apex, deeply sulcate, 5-6 mm. long, the persistent 3 styles about 2 mm. long. In wet pinelands, swamps and depressions,

about ponds and lakes, and along ditches in s.e. Tex., May-Aug.; from Fla. to Tex., n. to Tenn. and N.C.

7. *Hypericum fasciculatum* Lam. SAND-WEED. Shrub to about 1 m. high; bark dark-brown, spongy-thickened, exfoliating in tissue-thin sheets; leaves verticillate, numerous, crowded, typically linear-filiform or very narrowly linear, coriaceous, revolute, 1-2 cm. long, mostly about 1 mm. wide, with a cluster of smaller leaves in the axils of the larger ones; flowers several terminating the upper branches; sepals linear, 3-4 mm. long, about 1 mm. wide; petals bright-yellow, obliquely apiculate, 7-8 mm. long; capsules ovoid to ovoid-conic, 4-5 mm. long, 3-lobed. *H. galioides* var. *fasciculatum* (Lam.) Svens. In wet places about ponds and lakes, in low pinelands and along forested streams, in s.e. Tex., June-Aug.; from Fla. to Tex., n. to N.C.

This species is closely allied to *H. galioides*. The juvenile leaves found on seedlings and sometimes on adult plants are very similar to the leaves found on that species.

8. *Hypericum nudiflorum* Michx. Shrub to 2 m. high, usually much smaller, the stems ligneous below, sending up long subherbaceous brown-barked 4-angled flowering branches; leaves ovate-lanceolate to linear-oblong, obtuse, thin, to about 7 cm. long, pale-green, minutely punctate beneath, revolute in drying, usually without axillary fascicles; flowers numerous, in open terminal dichotomous cymes; bracts lance-subulate, 2-3 mm. long; sepals firm, linear to oblong, 2-5 mm. long; petals to 1 cm. long; styles 3; capsules ovoid, to 7 mm. long, with 3 inwardly projecting placentae. In moist sandy woods, thickets or swamps in e. Tex., June-Aug.; from Fla. to Tex., n. to Va. and Tenn.

9. *Hypericum apocynifolium* Small. Shrub 4-7 dm. high, the stems with red somewhat shreddy bark and the branchlets narrowly 4-winged; leaves essentially sessile, oblong to oblong-elliptic, more or less cuneate at the base, rounded to emarginate at apex, 2-4 cm. long, thin, bright-green, pale beneath, minutely punctate, rarely revolute; flowers 3 to 5 in terminal cymes; sepals spatulate to elliptic or oval, obtuse, persistent, 3-5 mm. long, at least one half as long as the petals; petals yellow, oblong, 8-9 mm. long; capsules oblong-conic, thick-walled, to 14 mm. long, acute. In swamps and marshes in n.e. Tex., June-Aug.; from Ga. and Fla. to Tex. and Ark.

10. *Hypericum cistifolium* Lam. Slender subherbaceous perennial; stem somewhat woody, reddish-brown, prominently 2-winged and simple or very sparingly branched, to 9 dm. high; leaves firm, linear-oblong to linear-lanceolate, to 3 cm. long and 6 mm. wide, obtuse to subacute at apex, the margins strongly revolute, sessile, subauriculate and clasping at the base, the solitary midnerve beneath keeled and continuous into the wing on the stem, with fascicles of smaller leaves in their axils; flowers numerous in terminal or axillary dichotomous cymes, the bracts subulate and about 3 mm. long; sepals ovate to elliptic or oval, to 3 mm. long and 1.5 mm. wide; petals yellow, convolute in bud, obliquely cuneate to obovate, 5-10 mm. long; filaments elongate; styles 3, coherent, somewhat persistent, the stigmas minute; capsule globose to globose-ovoid, to 7 mm. long, 3-lobed, 1-celled; seeds wrinkled. In sandy soils, rare in extreme s.e. Tex., June-Aug.; from Fla. to Tex., n. to N.C.

The peculiar thin-tissued, somewhat auriculate-clasping base of the leaves, and the keeled midnerve that continues into a stem-wing, distinguish this species.

11. *Hypericum sphaerocarpon* Michx. Plant with usually simple herbaceous stems from a somewhat woody base, 3-5 dm. high, the stems angled with 4 narrow salient lines; leaves sessile, nearly linear to narrowly oblong, with a somewhat clasping base, obtuse to acute at apex, 3-7 cm. long, to 15 mm. wide; cymes naked, compound, usually many-flowered; sepals ovate to elliptic-lanceolate, acute, 3-5 mm. long, about equal in length and size, the larger ones 1.5-3 mm. wide; petals elliptic to elliptic-oblong, 5-9 mm. long; capsule depressed-globose to broadly ovoid, firm, 5-7 mm. long at maturity, 1-celled; seeds large, oblong, very rough-pitted. On barren embankments and in prairies in n.e. Tex., May-July; from Ala. to Tex., n. to O., Ind., s. Wisc., Ia. and e. Kan.

12. *Hypericum setosum* L. Plant herbaceous, scabrous-tomentose to -pilose throughout, the stem simple or sometimes virgately branched, to 75 cm. high; leaves sessile, numerous, erect-appressed, ovate to linear-oblong or lanceolate, acute at apex, the margins somewhat revolute, to 15 mm. long and 4 mm. wide, gradually reduced up the stem; flowers few in cymes; sepals ovate to ovate-lanceolate or elliptic, acute to acuminate, to 4 mm. long, conspicuously ciliate; petals yellow, 5-6 mm. long, obliquely oblong-elliptic, obtuse;

styles 3, subsistent; capsule ovoid-oval, 4-5 mm. long. In bogs and wet pinelands in s.e. Tex., June-Sept.; from Fla. to Tex., n. to Va.

13. *Hypericum mutilum* L. Plant annual or perennial; 3-9 dm. high, with weak slender erect to ascending stems, widely branching above, sometimes forming extensive colonies, often with leafy-bracted decumbent bases; leaves ovate to lanceolate or narrowly oblong, sessile and partly clasping at base, rounded to broadly obtuse at apex, mostly 5-nerved, to 35 mm. long and 15 mm. wide; cyme in well-developed plants diffuse and somewhat leafy-bracted, the ultimate bracts setaceous; flowers light-yellow, about 4 mm. across; sepals variable in length and size, linear to linear-lanceolate or elliptic-oblong, equal to or much-exceeding the capsules; stamens 6 to 12; capsules subglobose to short-ellipsoid, the rounded summit capped by the short persistent styles that are about 1 mm. long. On the edge of and in water of streams, ponds, swamps and other wet situations in cen. and e. Tex., May-Oct.; from Fla. to Tex., n. to s. N.E., cen. N.Y., O., Ill., Mo. and Kan.

Those plants with sepals broadly lanceolate to oblong and foliaceous have been segregated as var. *latisepalum* Fern.

14. *Hypericum gymnanthum* Engelm. & Gray. Plant herbaceous, almost simple, with strict stem and branches, to 9 dm. high, usually much smaller; leaves firm, clasping, 5- to 7-nerved, deltoid-cordate, acute to obtuse at apex, about 15 mm. long and 1 cm. wide below middle; cymes naked, elongated, the floral leaves reduced to small subulate bracts 3-4 mm. long; sepals thickish, erect, lanceolate, acuminate, 3-5 mm. long; petals 3-6 mm. long; stamens 10 to 12; styles 3, persistent, about 0.75 mm. long, the stigmas only slightly dilated; capsule ellipsoid-conical, pointed, about 4 mm. long. In sandy soils in barrens or low ground in s.-cen. and s.e. Tex., June-July; from Fla. to Tex., n. locally to N.Y., N.J., Pa., W.Va., O., Ill., Mo. and e. Kan.

15. *Hypericum pauciflorum* H.B.K. Plant somewhat succulent, to 7 dm. high, usually with several herbaceous stems arising from a somewhat woody base, rarely simple, the individual stems then much-branched above the middle, the floral branches strongly 2-edged and somewhat flattened; leaves bluish-green, all sessile and more or less clasping, coriaceous, with conspicuously revolute margins, those on the lower and middle part of the stem lanceolate to linear and more or less spreading, to 3 cm. long and 7 mm. wide, gradually reduced above into the flowering branches; flowers distant, in the axils of the uppermost nodes; sepals linear-lanceolate to elliptic-lanceolate, acute, 5-6 mm. long; petals orange-yellow, 8-10 mm. long; capsules ovoid-conic, dark-brown, 4.5-6 mm. long, usually about as long as sepals, the 3 persistent styles 3 mm. long, with conspicuously discoid-capitate stigmas; seeds oblong, light-brown, pitted, about 0.5 mm. long. On dunes and in grassy sandy fields along the coast and in the Rio Grande Plains in s. Tex., Mar.-Oct.; also in adj. and cen. Mex.

16. *Hypericum Drummondii* (Grev. & Hook.) T & G. NITS-AND-LICE. Plant annual, to 8 dm. high, the stem and the alternate bushy branches rigidly erect, mostly densely punctate throughout; leaves numerous, linear to linear-subulate, ascending to nearly erect, not appressed, 1-nerved, 6-20 mm. long; flowers short-pedicelled, mostly solitary in the axils along the upper part of the leafy branches; sepals narrowly lanceolate, acute, 3-5 mm. long; petals orange-yellow, withering before noon; stamens 10 to 20; capsules ovoid, 4-5 mm. long, reddish-brown, barely as long as or but slightly exceeding the sepals; seeds oval, dark-brown, strongly ribbed and rugose, about 1 mm. long. *Sarothra Drummondii* Grev. & Hook. In dry sandy or gravelly soils in fallow fields, open scrub oak and cedar-oak flatwoods in cen. and e. Tex., July-Sept.; from Fla. to Tex., n. to Md., W.Va., O., Ind. s. Ill., Ia. and s.e. Kan.

17. *Hypericum gentianoides* (L.) B.S.P. ORANGE GRASS, PINEWEEED. Plant an erect annual, to 6 dm. high, the stem and erect bushy branches threadlike and wiry; leaves minute subulate scales, appressed, 1-3 mm. long; flowers minute, mostly sessile and at the nodes along the branches; sepals linear to linear-lanceolate, about 2 mm. long; capsules lance-subulate, acute, 5-7 mm. long; seeds about 0.5 mm. long, pale-brown, somewhat areolate. *Sarothra gentianoides* L. In dry gravelly or sun-baked sandy soil in cen. and e. Tex., May-Sept.; from Fla. to Tex., n. to s. Me., s. Ont., O., Ind. and Wisc.

18. *Hypericum virginicum* L. MARSH ST. JOHN'S-WORT. Plants stoloniferous, the stem simple or bushy-branched (especially above), to 7 dm. high; leaves sessile and cordate or clasping at base, oblong-elliptic to ovate-oblong, rounded at the retuse to apiculate

apex, the principal leaves to 7 cm. long and 3 cm. wide, dark-punctate beneath, dotted with translucent glands, often purplish; flowers in small clusters in the upper axils and terminal; sepals linear-elliptic to lanceolate, obtuse to acute, 4-7 mm. long; petals flesh-color or mauve, 7-10 mm. long; filaments free except near the base, the 3 fascicles alternating with 3 large orange-colored glands; capsule ellipsoid, tapering to the apex, about 1 cm. long, the mature styles 2-3 mm. long; seeds tan-color, oblong, pitted, about 1 mm. long. *Triadenum virginicum* (L.) Raf. In or on the edge of water along streams, in bogs and swamps, and about lakes and ponds in e. Tex., Aug.-Oct.; from Fla. to Tex., n. to N.S., s. N.E., N.Y., O., Ind. and Ill.

19. *Hypericum Walteri* Gmel. Similar in habit to *H. virginicum* but usually larger and more branched; leaves oblong to oblong-oblancheolate, obtuse to rounded at the apex, tapering into the slender petiole, to 15 cm. long and 35 mm. wide, yellowish-green above, pale-glaucous and translucent-dotted beneath, often reddish-tinged; flowers in small axillary and terminal clusters; sepals linear-elliptic, obtuse, 3-4 mm. long; petals reddish, 5-7 mm. long; filaments united to about or above the middle; capsules ellipsoid-cylindric, rounded or tapered at apex, 7-11 mm. long, the styles about 1 mm. long; seeds oblong, dark-brown at maturity, about 0.75 mm. long. *H. petiolatum* Walt., *H. tubulosum* Walt. var. *Walteri* (Gmel.) Lott, *Triadenum petiolatum* (Walt.) Britt., *T. Walteri* (Gmel.) Gl. In or on the edge of water along streams, in bogs and swamps, and about ponds and lakes, sometimes on cypress knees and trunks, logs and occasionally on moist sandy wooded slopes, in e. Tex., Aug.-Oct.; from Fla. to Tex., n. to Md., W.Va., s. Ind. and s.e. Mo.

20. *Hypericum tubulosum* Walt. Erect rhizomatous plant with stem simple or branched above, 3-8 dm. tall, glabrous throughout; leaves sessile, ample, lacking translucent glands or superficial dots on lower surface, oblong to elliptic-oblong or elliptic-oblancheolate, 5-15 cm. long, 2-5 cm. wide, scarcely tapered to a broadly rounded to truncate or somewhat cordate base, obtuse to broadly rounded at apex; cymes axillary, few-flowered, on peduncles to 3 cm. long; sepals oblong-lanceolate, acute, 4-6 mm. long; petals pink, 5-8 mm. long; fruit 9-11 mm. long; styles 3, about 1 mm. long. *Triadenum tubulosum* (Walt.) Gl. In wet soil of wooded swamps, open floodplain woods and on lake shores in s.e. Tex. where recently found in Newton Co., Sept.-Oct.; mainly on Coastal Plain from s.e. Va. to s.e. Tex., n.w. in the interior to s. Mo. and s. O.

FAM. 119. ELATINACEAE DUM.

WATERWORT FAMILY

Low annual or perennial herbs with opposite simple leaves with membranous paired stipules between them and small regular axillary flowers; the persistent or marcescent sepals and petals imbricated in the bud; stamens as many as the petals and alternate with them or twice as many; ovary 2- to 5-celled, the placentae axile; valves of capsule alternate with dissepiments; seeds several to many, oblong-cylindric, straight or curved, usually with a reticulate surface pattern.

A family of the following two genera and about 40 species of cosmopolitan distribution.

1. Plants less than 1 dm. tall, creeping, glabrous; flowers 2- or 3-merous; sepals obtuse, not scarious-margined1. *Elatine*, p. 1066.
1. Plants 1 dm. or more tall, erect-ascending, glandular-puberulent; flowers 5-merous; sepals cuspidate, scarious-margined2. *Bergia*, p. 1067.

1. ELATINE L.

WATERWORT

Dwarf more or less prostrate plants of wet places, often rooting at the nodes; flowers 1 or 2 to a node; sepals and petals each 2 or 3; petals membranous, hypogynous, usually orbicular; styles or sessile capitate stigmas 2 to 4; capsule membranous, 2- to 4-celled, several- to many-seeded, 2- to 4-valved, the partitions left attached to the axis or evanescent.

A genus of about 20 species in fresh-water habitats in temperate and warm regions.

- 1. Leaves linear to narrowly spatulate, often emarginate at tip; largest seeds with 16 to 25 pits in each row1. *E. triandra*.
- 1. Leaves obovate to narrowly oblong-obovate or rarely linear-spatulate, not emarginate at tip; largest seeds with 9 to 15 pits in each row ..2. *E. brachysperma*.

1. *Elatine triandra* Schkuhr. Matted creeping plant; leaves mostly truncate or emarginate, to 7 mm. or more long and 3 mm. wide; flowers sessile, 3-merous; seeds borne along entire length of thickened central axis, horizontally divergent, slender-cylindric and curved, with meandering obscure longitudinal ridges and somewhat angular pits in each row, the larger seeds with 16 to 25 pits in each row. In mud and shallow water in cen. Tex., Mar.-Oct.; from Wisc. to Alta. and Wash., s. to Tex. and n. Mex.; also Euras.

2. *Elatine brachysperma* Gray. Plant forming tiny low spreading mats to 5 cm. across, the branches somewhat ascending; leaves to 6 mm. long and 2 mm. wide; flowers sessile, 3-merous; sepals 2 or with a third greatly reduced; petals 3, pinkish; capsule depressed, 3-celled; seeds shortly oblong-ellipsoid, with 9 to 15 pits in each irregular row, the pits separated by acute cross-ribs. *E. triandra* var. *brachysperma* (Gray) Fassett. Rare on mud or in shallow water in cen. Tex., Mar.-Oct.; O. and Ill. w. to Ore., s. to Tex., Ariz. and Calif.

2. BERGIA L.

A small essentially tropical or subtropical genus of about 20 species.

1. *Bergia texana* (Hook.) Walp. Diffuse or ascending plant that is branched from the base, to 4 dm. tall, more or less glandular-puberulent throughout; flowers shortly pedicelled, 1 to 3 in the axils of the leaves; leaves elliptic-oblong to oblong-ob lanceolate, tapering at base, serrulate, to 3 cm. long; stipules lanceolate, deeply serrate; sepals 5, to 3.5 mm. long, acuminate, with thickened greenish midnerve and wide scarious margins, roughened on the keeled midnerve; petals 5, white, oblong, shorter than the sepals; stamens 5 or 10; fruit subglobose, 2-3 mm. in diameter, firm-textured, 5-carpellate; seeds glossy, light-brown, elliptic-oblong, curved, obscurely reticulate. In ditches, swamps, marshes, and on mud about ponds and on wet banks in s. Tex., June-Oct.; from Ark. to Tex. and s. Calif., n. to s. Ill., Mo., S.D. and Wash.

FAM. 120. FRANKENIACEAE S. F. GRAY
FRANKENIA FAMILY

Low perennial herbs or small shrubs; leaves opposite, subsessile or shortly petiolate, entire, exstipulate, the pairs jointed at base by a ciliated line; flowers perfect, 4- to 7-merous, solitary or in cymes; sepals united to form a tube; petals free, imbricate; stamens usually 6; ovary 1-celled, the style 2- to 4-cleft; fruit a 1-celled capsule included in the persistent calyx; seeds 2 to several, oval to oblong, with parietal placentation.

About 90 species in 4 genera, mostly in the Mediterranean region.

1. FRANKENIA L.

Characters of the family. About 80 species of saline habitats.

- 1. Leaves sessile, linear, when mature 3-5 mm. long, dorsally sulcate, glabrous beneath; calyx lobes less than 1 mm. long1. *F. Jamesii*.
- 1. Leaves with petioles 1-2 mm. long, when mature about 10 mm. long, plane above, densely farinose beneath; calyx lobes about 2 mm. long2. *F. Johnstonii*.

1. *Frankenia Jamesii* Torr. Small much-branched shrub with jointed stems from a woody base, to about 3 dm. tall, the leafy portion more or less hispidulous; leaves small, linear, pointed, dorsally sulcate, with strongly revolute margins, 3-5 mm. long and 1

mm. wide, the fascicled leaves shorter; flowers sessile, solitary at end of branchlets or becoming cymose-clustered on the branches; calyx tube strongly ribbed, 4-5 mm. long, the 5 toothlike lobes less than 1 mm. long; petals 5, clawed, white, erose-denticulate at the truncated apex, about twice as long as the calyx tube; capsule linear, angled, about 5 mm. long. On dunes about salt flats and lakes in the Trans-Pecos and Plains Country, usually associated with gypsum, Apr.-Aug.; in w. Tex., N.M. and Colo.

2. *Frankenia Johnstonii* Correll. Shrub to 3 dm. high, the woody base supported by dark-brown wiry roots and giving rise to several or many elongated arching or strongly recurved willowy stems, the entire plant grayish- or bluish-green; stems subherbaceous, about 1 mm. thick, sparsely pilose with short whitish appressed or incurved hairs; internodes mostly 1-1.5 cm. long; leaves distinctly petioled, oblanceolate to oblong-elliptic, rounded at base, minutely apiculate at the rounded apex, to 13 mm. long and 4 mm. wide, the margins somewhat revolute, the upper surface sparsely short-pilose with appressed hairs, the lower surface farinaceous and hoary; petioles brownish-green, 1-2 mm. long, slightly winged with the membranous pubescent wings united around the node; flowers sessile and solitary at the apex of short axillary branchlets; calyx tube strongly ribbed, about 4 mm. long, the 5 triangular lobes about 2 mm. long; petals 5, clawed, white, elliptic-oblanceolate, erose at the apex, about twice as long as the calyx; stamens 6, of various lengths, included; styles 3-cleft. Rare on saline flats and rocky gypseous hillsides in the Rio Grande Plains of s. Tex., Nov.-Apr.; endemic.

FAM. 121. TAMARICACEAE LINK.¹³²

TAMARISK FAMILY

Shrubs or small trees; leaves alternate, exstipulate, sessile, small and scalelike, entire, commonly imbricated; flowers mainly perfect, regular, in spicate racemes that are usually collected to form a panicle; sepals 4 or 5, imbricated; petals 4 or 5, distinct, somewhat imbricated; disk 5- or 10-lobed or obsolete; stamens 4, 5, 8 or 10, the distinct filaments free, the anthers opening lengthwise; ovary 1-celled, superior, with 3 to 5 basal placentae; stigmas 2 to 5, distinct; ovules 2 to many on each placenta; fruit a capsule; seeds erect, terminating in a sessile tuft of hairs.

More than 60 species in four genera, all natives of the Old World.

1. TAMARIX L. TAMARISK. SALT CEDAR

Deciduous shrubs or small trees with irregularly and widely spreading slender terete stems; the ultimate small branchlets deciduous with the leaves; leaves clasping or sheathing; flowers small, short-pedicel or sessile; petals pink or white, inserted under the disk; capsule dehiscent into 3 to 5 valves; seeds numerous.

About 50 species in the Old World, many of which are cultivated for their feathery foliage and profuse pink or white flowers. Occasionally planted for windbreaks and for sand binding. Most have become naturalized in such places as along streams (especially if saline), in and about salt flats and in waste places generally. They flower periodically throughout the year.

1. Flowers 4-merous, occasionally with more than 4 stamens 5. *T. parviflora*.
1. Flowers 5-merous, occasionally with more than 5 stamens (2)
- 2(1). Staminal filaments arising from the alternating disk-lobes (3)
2. Staminal filaments not as above (4)
- 3(2). Racemes mostly on last year's branches, 6-9 mm. broad (in dried material); petals ovate to broadly trulliform-ovate, more than 2 mm. long 1. *T. africana*.
3. Racemes mostly on green branches, 4-5 mm. broad; petals elliptic to somewhat ovate-elliptic, less than 2 mm. long 4. *T. gallica*.

¹³² Adapted from Bernard R. Baum in *Baileya* 15(1):19-25. 1967.

- 4(2). Staminal filaments inserted between the more or less retuse lobes of the disk; petals caducous (sometimes 1 or 2 persisting) 2. *T. aphylla*.
4. Staminal filaments as above but with at least 3 of them inserted under the disk near the margin; petals persistent after maturity (5)
- 5(4). Sepals more or less entire; petals ovate to elliptic; flowers of those racemes that occur on green branches with 1 or 2 of the filaments inserted between lobes of disk 3. *T. chinensis*.
5. Sepals denticulate; petals obovate; all filaments of all flowers inserted below disk near margins 6. *T. ramosissima*.

1. *Tamarix africana* Poir. Bark black to dark-purple; leaves sessile; racemes 3-7 cm. long, 6-9 mm. broad (in dry material), those occurring on green branches of the current year somewhat smaller; bracts longer than pedicels; flowers pentamerous; sepals subentire, the outer 2 slightly keeled and longer than the inner more obtuse ones; petals ovate to broadly trulliform-ovate, about 2.5-3 mm. long in vernal flowers, 3 mm. long or more in aestival; staminal filaments inserted on gradually tapering lobes of disk. Nat. of Eur. and the Medit. region; introd. in Calif., Ariz., Tex. and S.C.

2. *Tamarix aphylla* (L.) Karst. Bark reddish-brown to gray; leaves vaginate; racemes 3-6 cm. long, 4-5 mm. broad; bracts longer than pedicels; flowers pentamerous; sepals entire, the inner somewhat larger; petals elliptic-oblong to ovate-elliptic, 2-2.25 mm. long, caducous, sometimes 1 or 2 persisting after maturity; staminal filaments inserted between the more or less retuse disk-lobes. Nat. of Afr. and the Middle East; introd. in Tex., Ariz. and Calif.

3. *Tamarix chinensis* Lour. Bark brown to black-purple; leaves sessile; vernal inflorescences of many dense racemes, aestival ones loose and of slender racemes; racemes 2-6 cm. long, 5-7 mm. broad; bracts equaling to slightly longer than pedicels; flowers pentamerous; sepals subentire, acute; petals elliptic to ovate, persistent after maturity, about 1.5-2.25 mm. long; filaments inserted between lobes of disk but from its lower part near the margin; in aestival flowers 1 or 2 filaments are inserted in the sinuses between the lobes and the other 3 or 4 under the disk near the margin. Nat. of the Far East; introd. and widespread in Can. and the U.S.

4. *Tamarix gallica* L. TAMARISCO, ROMPEVIENTOS. Bark blackish-brown to deep-purple; leaves sessile; racemes 2-5 cm. long, 4-5 mm. broad; bracts longer than pedicels, not exceeding the calyx; flowers pentamerous; sepals acute, entire or subentire; petals caducous, elliptic to slightly ovate-elliptic, 1.5-1.75 mm. long; staminal filaments inserted on apices of the gradually attenuating lobes of disk. Nat. of s. Eur.; introd. and rare in s. U.S.

5. *Tamarix parviflora* DC. Bark brown to deep-purple; leaves sessile; racemes more often on last year's branches, 1.5-4 cm. long, 3-5 mm. broad; bracts diaphanous, longer than pedicels; flowers tetramerous; sepals eroded-denticulate, the outer 2 trulliform-ovate, acute and keeled, the inner 2 ovate and obtuse; petals parabolic or ovate, 2 mm. long; staminal filaments emerging gradually from the disk-lobes. Nat. of the Medit. region; introd. and widespread in Can. and the U.S.

6. *Tamarix ramosissima* Ledeb. Bark reddish-brown; leaves sessile; racemes 1.5-7 cm. long, 3-4 mm. broad; bracts longer than pedicels; flowers pentamerous; sepals more or less acute, eroded to irregularly denticulate, the inner 3 broader than the outer; petals 1-1.75 mm. long, obovate to broadly elliptic-obovate; filaments inserted under the disk near the margin between the usually emarginate lobes. Nat. of Euras.; introd. and widespread mainly in s. U.S.

FAM. 122. FOUQUIERIACEAE DC.

OCOTILLO FAMILY

Shrubs with wandlike branches or (in *Idria*) small trees with a massive trunk and relatively small branches; spines numerous, each formed by hardening of the persistent petiole and midrib of the leaf of the first season of growth; leaves of succeeding seasons produced in clusters in the axils of the spines; flowers showy, in terminal panicles; sepals 5, imbricated, unequal, persistent; petals united to form a 5-lobed tube; stamens 10 to

19, attached to base of corolla tube, the filaments thickened at base; fruit a capsule, incompletely 3- or 4-celled; seeds several, winged or copiously fringed on the angles.

A family of two genera, the following and *Idria* of Baja California.

1. FOUQUIERIA H.B.K. OCOTILLO. CANDLEWOOD

Characters of the family. About 7 species centered in Mexico with one in southwestern United States.

1. *Fouquieria splendens* Engelm. Shrub with several slender wandlike branches from a root crown; branches erect- or sinuously-ascending, to 9 m. tall and 6 cm. in diameter, strongly grooved and ridged by decurrent base of spines, the bark grayish; spines to 2 cm. long; leaves sessile or nearly so, obovate to spatulate, to 5 cm. long and 3 cm. wide, entire, glabrous, early-deciduous; inflorescence to 25 cm. long; pedicels to 8 mm. long; sepals suborbicular, scarious, 4-6 mm. long; corolla scarlet, to about 15 mm. long, the rounded lobes strongly revolute; stamens red, protruding well beyond the corolla; style divided into 3 or 4 elongated filiform branches; capsule about 15 mm. long, 3-valved, persistent; seeds fringed with long whitish hairs. On rocky exposed slopes, along rocky draws and on sandy plains in w. Edwards Plateau and Trans-Pecos, Mar.-June; from Tex. to Calif. and n. Mex.

The periodic, not seasonal, appearance of the leaves of this species is dependent upon rainfall; their appearance is a sure indication that rain has only recently fallen in that particular region.

FAM. 123. CISTACEAE JUSS.¹³³ ROCKROSE FAMILY

Herbs or low shrubs; leaves simple, alternate, opposite or whorled, stipulate or exstipulate, entire; flowers hypogynous, regular, perfect, variously arranged; sepals 5 with the 2 outer smaller, distinct or with the outer 2 attached to the inner; petals 3, 5 or absent in cleistogamous flowers; stamens few to numerous; pistil 1, of (2 or) 3 to (5 to 10) united carpels; ovary 1-celled or imperfectly (2- or) 3- to (5- to 10-) celled; fruit a capsule.

About 180 species in 5 or 6 genera in temperate and subtropical regions of both hemispheres.

- 1. Petals 5 (rudimentary or lacking in cleistogamous flowers), yellow; stigma capitate; capsule 1-celled with filiform placentae; pubescence completely or in part stellate1. *Helianthemum*, p. 1070.
- 1. Petals 3, reddish; stigma fimbriate-plumose; capsule incompletely 3-celled from the broad shieldlike placentae; pubescence of only simple trichomes2. *Lechea*, p. 1072.

1. HELIANTHEMUM MILL. ROCKROSE. FROSTWEED

Annual or perennial herbs or shrubs with alternate (all American species) or opposite (some Eurasian) exstipulate (all American) or stipulate (some Eurasian) leaves and dimorphic (petaliferous or apetalous) or monomorphic flowers; sepals (3) 5 with the 2 outer attached to the inner 3; petals (when present) 5, usually yellow (as in all American), fugacious; stamens 3 to 8 in the cleistogamous and 10 to 50 (to 100) in the chasmogamous flowers; pistils (2-) or 3-carpellate; stigma capitate; style short to elongate; capsule 1-celled with 2 or 3 parietal placentae bearing few to numerous seeds.

A genus of approximately 100 species principally of the Northern Hemisphere and largely centered about the Mediterranean.

¹³³ Contributed by Robert L. Wilbur. Cf. his more detailed treatment in C. L. Lundell, *Flora of Texas II*: 1-17. 1969.

1. Lower epidermis of cauline leaves clearly visible and not completely masked by the dense pubescence; lower stem with spreading pilose trichomes to 2.5 mm. long; seed coat papillate, not readily separable when wetted 1. *H. carolinianum*.
1. Lower epidermis of cauline leaves completely masked by the dense stellate pubescence; lower portion of stems variously pubescent but never with pilose trichomes; seed coat smooth or indistinctly pebbled, gelatinous and readily separable when wetted (2)
 - 2(1). Leaves densely stellate-tomentose above, ash-gray, their epidermis masked from view; Chisos Mts. of Trans-Pecos Texas 2. *H. glomeratum*.
 2. Leaves sparingly to moderately stellate-tomentose above but still green and with a clearly visible epidermis; central and eastern Texas (3)
 - 3(2). Inner cleistogamous sepals 4 mm. long or longer; outer cleistogamous sepals 1.4 mm. long or longer; cleistogamous capsules 3 mm. long or more, with 12 to 20 seeds; petals 6-12 mm. long; chasmogamous capsules 3.8 mm. long or more, 20- to 35-seeded; cleistogamous flowers loosely racemose 3. *H. georgianum*.
 3. Inner cleistogamous sepals less than 2 mm. long; cleistogamous capsules less than 2 mm. long, 1- (2-) seeded; petals 4-6.4 mm. long; chasmogamous capsules 3 mm. long or less, 1- to 6-seeded; cleistogamous flowers glomerate 4. *H. rosmarinifolium*.

1. *Helianthemum carolinianum* (Walt.) Michx. Perennial herb with ascendent stems to 38 cm. tall, densely beset below with trichomes to 2.5 mm. long; basal leaves rosulate with blades mostly 1-4 cm. long; cauline leaves few and remote, sparsely stellate-pubescent beneath; flowers few in a loose scorpioid cyme, almost all petaliferous; pedicels and calyces with spreading trichomes to 1.5 mm. long; free portion of outer chasmogamous (= petaliferous) sepals (2.5-) 4-5.5 (-7.5) mm. long; inner sepals 6-14 mm. long; petals 8-18 mm. long; capsule 6-10.5 mm. long with 80 to 135 papillate seeds. Sandy fields and roadsides or open woods of e. Tex., Mar.-May; from Fla. to Tex., n. to s.e. N.C. and s. Ark.

2. *Helianthemum glomeratum* (Lag.) Dun. Plant suffrutescent with ascendent stellate-pubescent to glabrate stems 1-5.5 (-8) dm. tall; cauline leaves 1-3.5 cm. long, usually oblanceolate, densely stellate-tomentose on both surfaces; flowers dimorphic but occasionally predominately or even exclusively either chasmogamous (= petaliferous) or cleistogamous (= apetalous); pedicels and calyces densely stellate-tomentulose; chasmogamous flowers mostly solitary at tips of the branches on filiform pedicels 7-20 mm. long and overtopping the subsessile or short-pedicellate cleistogamous flowers; *chasmogamous flowers*: free portion of outer sepals 0.6-4 mm. long and with inner sepals 3-7 mm. long; petals 4-9 mm. long; capsule 3.5-4.5 mm. long with 6 to 20 slightly pebbled seeds with a separable membrane when wetted; *cleistogamous flowers*: free portion of outer sepals 0.6-3 mm. long and the inner sepals 2.4-5 mm. long; capsule 1.6-3.6 mm. long with (1 or) 2 to 7 (to 11) seeds similar in pattern to the chasmogamous. Dry open woods of the Chisos Mts. of the Trans-Pecos, June-Aug.; s. to Guat.

3. *Helianthemum georgianum* Chapm. Perennial herb with ascendent stellate-tomentose stems 1-4 dm. tall; basal leaves (when present) rosulate with blades 1-2.8 cm. long; cauline leaves greenish but stellate-pubescent above while hoary and stellate-tomentose beneath with both the midvein and the secondary veins prominently elevated beneath; flowers dimorphic, in loose racemose cluster of 2 to 7; pedicels and calyces densely short stellate-canescens; *chasmogamous flowers*: pedicels 5-15 mm. long; free portion of outer sepals 1.5-3.5 mm. long; inner sepals 3.6-6.6 mm. long; petals 6-12 mm. long; stamens 15 to 36; capsule 3.8-5.8 mm. long; seeds 20 to 35, smooth and (when moistened) the membrane separable; *cleistogamous flowers*: pedicels 0.6-3(-6) mm. long; free portion of outer sepals 1.4-2.2 mm. long; inner sepals 3-4.2 mm. long; stamens 3 to 8; capsule 4-5.4 mm. long; seeds 12 to 20. *H. Bicknellii* of Tex. auth., not Fern. Dry open sandy fields or woods of e. Tex., Apr.-June; from Fla. to Tex., n. to s.e. N.C. and s. Okla.

4. *Helianthemum rosmarinifolium* Pursh. Perennial herb with ascendent stellate-tomentose stems 1.3-5 dm. tall; cauline leaves 5 to 14 times as long as wide, green and stellate-pubescent above, hoary and densely stellate-tomentose beneath with the midvein strongly elevated and the secondary veins only slightly elevated; flowers dimorphic; pedicels and calyces stellate-tomentose; chasmogamous flowers solitary at the tips of the branches on filiform pedicels 1-2.2 cm. long overtopping the subsessile glomerate cleistogamous flowers; *chasmogamous flowers*: free portion of outer sepals 1.3-2.5 mm. long; inner sepals 2.5-4.3 mm. long; petals 4-6.4 mm. long; stamens 15 to 24; capsule 2-3 mm. long; seeds 1 to 6, smooth and with a thin separable membrane when moistened; *cleistogamous flowers*: pedicels in fruit 0.5-3 mm. long; free portion of the outer sepals 0.5-1 mm. long; inner sepals 1.5-1.8 mm. long; stamens 3 to 5; capsule 1.3-1.7 mm. long; seeds 1 (or 2). Sandy fields, roadsides and open woods of e. Tex., Apr.-June; from Fla. to Tex., n. to s.e. N.C. and Ark.

2. LECHEA L. PIN-WEED

Perennial herbs or somewhat suffruticose; leaves alternate, opposite or whorled, exstipulate; flowers small, variously arranged; sepals 5, the 2 outer very unlike and much shorter to somewhat longer than the inner; petals 3, reddish; stamens (3 to) 6 to 15 (to 25); pistil 3-carpellate; stigmas 3, fimbriate; style lacking; capsule incompletely 3-celled by the shieldlike partitions; seeds 1 to 6.

A primarily eastern North American genus of 17 species ranging from Nova Scotia to Hispaniola and Guatemala.

1. Mid-cauline leaves wider than 3 mm.; pubescence of aerial stems and inflorescence branches spreading-pilose 1. *L. mucronata*.
1. Mid-cauline leaves less than 3 mm. wide; pubescence of aerial stems and inflorescence branches closely appressed-pubescent (2)
 - 2(1). Fruiting pedicels 3-5 mm. long and both strikingly secund and bending away from the stem at an angle of 90° or more; calyx more than 3 mm. in diameter; incomplete partitions within capsules firm and bony; seeds 6 2. *L. san-sabeana*.
 2. Fruiting pedicels less than 3 mm. long and not both conspicuously secund and deflexed, more or less ascendent; calyx less than 3 mm. in diameter; incomplete partitions with capsules delicate to thin-chartaceous but never rigid and bony; seeds typically 3 or less (3)
 - 3(2). External sepals usually equaling or longer than the internal; capsules 1.3-1.5 mm. wide, usually 3-seeded; eastern Texas 3. *L. tenuifolia*.
 3. External sepals usually shorter than the inner sepals or equaling them; capsules 1.2-1.3 mm. wide, usually 1- or 2-seeded; western Texas 4. *L. mensalis*.

1. *Lechea mucronata* Raf. Perennial herb with aerial stems (1.5-) 3-9 dm. tall, bearing villous or spreading-pilose trichomes and with mid-cauline leaves 3 mm. wide or more; flowers few to several together forming a compact glomerule; pedicels mostly 0.5-1 (-1.5) mm. long; calyx subglobose; inner sepals deeply concave, scariously-margined, 1.3-2.2 mm. long; outer sepals slightly shorter to somewhat longer than the inner, 1.9-2.2 mm. long; capsule 1.4-2.1 mm. long, (2 or) 3 (or 4)-seeded. *L. villosa* Ell. and its var. *macrotheca* Hodg., *L. divaricata* of auth., not Britt. Sandy fields and roadsides or open woods and hillsides principally from the e. half of Tex., June-Nov.; from Fla. to Tex., n. to s. N.H. and Neb.

2. *Lechea san-sabeana* (Buckl.) Hodg. Perennial herb with aerial stems 1.5-3.5 dm. tall, bearing strigillose or strongly ascendent trichomes and with narrowly linear cauline leaves less than 2 mm. wide; flowers distantly spaced and secund with strongly deflexed pedicels 3-5 mm. long; calyx conspicuously triangular in cross section and subglobose in general outline; inner sepals conspicuously keeled at maturity, about 2 mm. long and 3 mm. wide, scariously margined; outer sepals equaling to somewhat longer than the inner sepals in flower but usually somewhat shorter in fruit, mostly 1-2 mm. long; capsule

1.2-2.2 mm. long, 6-seeded and incompletely partitioned by a crustaceous yellowish dissepiment. *L. Drummondii* (Spach) T. & G. Roadsides, fields or open woods of e.-cen. Tex., Apr.-June; endemic.

3. *Lechea tenuifolia* Michx. Perennial herb with aerial stems 1.2-2.5 (-4) dm. tall, with strigose or strongly ascendent hyaline trichomes and with mid-cauline leaves about 1.5 mm. wide or less; flowers racemose and frequently secund on appressed pedicels 1-1.5 mm. long; calyx subglobose; inner sepals occasionally noticeably keeled at maturity, 1.6-2.2 mm. long; outer sepals equaling to conspicuously longer than the inner but rarely slightly shorter, (1.6-) 2-3 mm. long; capsule depressed-globose, 1.4-2.1 mm. long, (2-) or 3- (to 5-) seeded. Incl. var. *occidentalis* Hodg. Roadsides, fields and open woods of e. Tex., May-July; Ga. to Tex. and n. to s. Me., Minn. and Neb.

4. *Lechea mensalis* Hodg. Perennial herb with aerial stems about 1.5-2.7 dm. tall, with strigillose to appressed-pilose trichomes and linear median cauline leaves less than 1.5 mm. wide; flowers racemose and borne on closely appressed pedicels 1-2 mm. long; calyx ovoid; inner sepals 1.8-2 mm. long and at maturity obscurely keeled; outer sepals usually shorter than the inner but occasionally equaling them, 1.2-2 mm. long; capsule asymmetrically ovoid, 1.6-1.8 mm. long, 1- or 2-seeded. Apparently restricted to the wooded summit of the Chisos Mts., June-Aug.; endemic.

FAM. 124. COCHLOSPERMACEAE PLANCH.

COCHLOSPERMUM FAMILY

Low-growing herbaceous or subshrubby plants (in ours) with simple or slightly branched erect stems that arise from a thick tuberous rootstock; leaves alternate, stipulate, long-petioled, palmately divided with the more or less cuneate lobes serrate; flowers large, perfect, several in a terminal raceme, occasionally solitary by abortion, sometimes slightly irregular; sepals and petals 5 each, distinct, imbricated, deciduous; petals of unequal width; stamens numerous, distinct, dimorphic, in 2 sets on opposite sides of the flower (one with long and the other with shorter filaments); filaments filiform; anthers 2-celled, linear, basifixed, opening by two terminal porelike slits; pistil 1, the subglobose ovary superior and 3-celled, the placentae parietal and sometimes intruding; capsule large, ellipsoid, with thick outer wall and thin inner wall that separate at maturity.

A small family of several genera and about 25 species, mostly in tropical America.

1. AMOREUXIA DC.

Characters of the family. A small American genus of 7 species.

1. *Amoreuxia Wrightii* Gray. Plants to about 5 dm. tall, glandular-puberulent throughout except the glabrous leaf blades; leaves on a petiole to 8 cm. long, 5-parted with the basal pair of segments sometimes shallowly lobed again, to 6 cm. long and 8 cm. wide; leaf segments obovate, cuneate at base, serrate above; flowers rather large; sepals oblong-elliptic, about 2 cm. long, with red broken striations; petals pinkish to orange-color, with a purplish blotch at base, about 35 mm. long; fruit oblong-ovoid, to 5 cm. long; seeds oblong-obovoid, flattened on one side in profile, the loose arilliform integument smooth. In limestone soils and on silty flats in Rio Grande Plains to w. Edward Plateau, May-July; also adj. Mex.

FAM. 125. KOEBERLINIACEAE ENGL.

ALLTHORN FAMILY

Intricately branched very thorny shrubs or small trees with green bark; branches short, stiff, divergent, terminating in a spine, somewhat hairy, becoming glabrate with age, neither glandular nor aromatic; leaves alternate, reduced to scales, ephemeral; inflorescence lateral, few-flowered, umbel-like or short-racemose; flowers perfect, regular; sepals

and petals 4; stamens 8, the filaments thickened at the middle; ovary 2-celled, stipitate; fruit a globose beaked berry; seeds 2 to 4, cochleate.

A monotypic family; included by some authors in the Capparidaceae.

1. KOEBERLINIA ZUCC. JUNCO. ALLTHORN

Characters of the family. Monotypic.

1. *Koerberlinia spinosa* Zucc. Plant globose, to 15 dm. tall, with a short trunk or branched from the base; spine-tipped branches to 1 dm. long and 3 mm. in diameter, yellow-green; pedicels slender, about 5 mm. long; sepals 1-2 mm. long; petals greenish-white or cream-color, to 6 mm. long; berry tan-color or black when ripe, shining, 3-4 mm. in diameter. On rocky open slopes, clay mounds, brushlands, and about arroyos along the lower Rio Grande and in the Trans-Pecos, Mar.-Oct.; from Tex. to s.e. Ariz. and n. Mex.

Plants that flower in the spring instead of late summer and have dark green spine-tipped branches 5-10 cm. long and 1.5-2 mm. in diameter, sepals 1.5-2 mm. long, and petals 4-6 mm. long have been segregated as var. *tenuispina* Kearn. & Peeb.

Besides the above variety, we have two strikingly distinct forms, if not species, of *Koerberlinia* in Texas. Typical plants have stout, simple branches that form a less compact shrub than the intricate atypical plants that have slender branches with slender, spreading secondary branches that, in turn, have minute branchlets mostly less than 1 cm. long. Further study may reveal that these plants comprise two separate entities.

FAM. 126. VIOLACEAE BATSCH¹³⁴ VIOLET FAMILY

Herbs, vines, shrubs or small trees with lobed or unlobed stipulate leaves; flowers irregular, perfect, 5-merous, polypetalous, axillary; calyx with separate sepals, often the two lowermost spurred; corolla bilaterally symmetrical, the lowermost petal spurred or gibbous; stamens hypogynous, with adnate introrse anthers, the filaments continued beyond the anther locules; ovary 1-celled, 3-carpellate, with parietal placentation, free from calyx; fruit a 3-valved capsule. Reduced cleistogamous flowers produced in most species during summer; with 5 sepals, 2 rudimentary petals that are not exposed and two stamens; pollen tubes grow directly from anthers into ovary.

About 800 species in 15 genera; cosmopolitan.

- 1. Sepals with auricles; lower petal spurred; stamens distinct, the lower two spurred 1. *Viola*, p. 1074.
- 1. Sepals without auricles; lower petals merely gibbous, not spurred; stamens united, the lower two not spurred 2. *Hybanthus*, p. 1078.

1. VIOLA L. VIOLET

Herbs (in Texas) with large stipules; petals unequal, the lowermost spurred; 5 stamens closely surrounding ovary but not fused, two lower ones bearing spurs that are housed in spur of basal petal; cleistogamous flowers produced by all species except *V. pedata*.

About 450 species, cosmopolitan, but chiefly in temperate North America and northern South America.

- 1. Plants with leafy aerial stems (2)
- 1. Plants without leafy aerial stems (4)
- 2(1). Plants annual 1. *V. Rafinesquii*.
- 2. Plants perennial, with underground rhizomes (3)
- 3(2). Flowers yellow; plants erect 2. *V. pubescens* var. *eriocarpa*.
- 3. Flowers blue; plants prostrate 3. *V. Walteri*.

¹³⁴ Contributed by Norman H. Russell.

3 to 5 leafy aerial stems; leaves cordate, uncut, smooth to sparingly hairy on all surfaces; stipules small and entire; flowers yellow; capsule glabrous to soft-tomentose; seeds 2-2.5 mm. long. Rich moist forests, often by streams, n.e. Tex., Mar.-May; n.e. Tex. to N.C., n. to Que. and Ont.

3. *Viola Walteri* House. Creeping perennial with slender underground rhizome and sometimes much-branching with leafy prostrate above-ground stems; leaves orbicular to reniform, entire, often purple-tinged on lower surface, pubescent on upper surfaces with short stiff hairs; stipules deeply cut; flowers blue-violet; cleistogenes on long axillary peduncles; fruits subglobose; seeds brown, 0.2 mm. long. Moist to somewhat dry rich deciduous forests in s.e. Tex., Mar.-Apr.; Tex. to Fla., n. to Va., O. and Ark.

4. *Viola primulifolia* L. Acaulescent perennial with cordlike rhizomes, producing runners throughout growing season (these take root at the nodes and form new crowns); leaves ovate-lanceolate to broadly ovate, variously pubescent, the blade tapering to a petiole as long as or longer than blade; flowers white with light-blue veins (especially on lower petal), small; capsules green, borne on erect peduncles; seeds 1.5-1.7 mm. long. Roadside ditches and open marshy fields, moderately abundant in e. Tex., Mar.-May; Tex. to Fla., n. to N.S., n. Ind. and Okla.

5. *Viola lanceolata* L. subsp. *lanceolata*. LANCE-LEAVED VIOLET. Acaulescent perennial with cordlike rhizomes, producing runners through growing season (these root at the nodes and form new crowns); leaves lanceolate, glabrous, about 3.5 to 5 times as long as broad; flowers white with bluish veins; capsules green, on erect peduncles; seeds light-brown, 1.4-1.5 mm. long. Roadside ditches and wet open fields, rare in n.e. Tex., Mar.-Apr.; Tex. to Ga., n. to Que. and Minn.

6. *Viola lanceolata* subsp. *vittata* (Greene) Russell. Acaulescent perennial, similar to subsp. *lanceolata* in most respects, differing in having vittate leaves often 3-5 dm. long and 5 to 14 times as long as broad. Drainage ditches and other wet open habitats, moderately frequent in e. Tex., Mar.-Apr.; Tex. to Fla., n. to s. Va. and s.e. Okla.

7. *Viola pedata* L. BIRD-FOOT VIOLET. Acaulescent perennial with thick vertical rootstock, not reproducing vegetatively; leaves deeply pedately divided into 3 or 5 major divisions and these lobed or divided further, the ultimate lobes spatulate; flowers large, 1.5-3 cm. broad, with flattened pansylike appearance; petals either uniformly pigmented whitish to dark-purple or the 2 upper petals dark-purple and the 3 lower petals pale-lilac or bluish; cleistogenes not produced; capsules on erect peduncles about equal in length to leaves. Open woods or fields, usually in sandy soil, in e. Tex., Mar.-Apr.; Tex. to Ga., n. to N.H. and Minn.

8. *Viola sagittata* Ait. ARROW-LEAVED VIOLET. Acaulescent perennial with thick horizontal or vertical rootstock which may occasionally fragment and form new crowns; leaves erect or slightly spreading, narrow, about 2 or 3 times as long as broad, sagittate, with 4 to 6 lobes or large teeth at the cordate base, moderately to densely pubescent; flowers blue to violet-purple; sepals with short auricles; cleistogenes abundantly produced during summer. Rather dry sandy woods and edges of woods in e. Tex., Mar.-Apr.; Tex. to Ga., n. to N.H. and Minn.

9. *Viola Lovelliana* Brainerd. Acaulescent perennial, reproducing vegetatively by fragmentation of the horizontal rhizome; leaves similar to those of *V. sagittata* but wider, with 3 to 5 broad lobes at base, from 2 times as long as broad to nearly as broad as long, moderately to densely pubescent, the central leaf lobe elongate and obovate; flowers deep-violet; sepal auricles short and ciliate; cleistogenes abundantly produced during summer. Rather dry deciduous woods in s. and e. Tex., also reported from w. Tex., Mar.-Apr.; Tex., La., Ark. and s.e. Okla.

10. *Viola triloba* Schwein. var. *triloba*. Acaulescent perennial, reproducing vegetatively by fragmentation of the horizontal rhizome; leaves spreading, as broad as or broader than long, with 4 to 6 broad lobes in lower half of blades, moderately to densely pubescent on both upper and lower surfaces; flowers violet-purple. Rich bottomland woods, sparingly in e. Tex., Mar.-Apr.; Tex. to Fla., n. to Vt., Ill. and e. Okla.

11. *Viola triloba* var. *dilatata* (Ell.) Brainerd. Similar to var. *triloba*, differing in having leaves deeply cut (almost to midrib) into 5 to 7 narrow lobes; similar habitats but not occurring with typical variety, more frequent, e. Tex., Mar.-Apr.; Tex. to Fla., n. to Pa., Ill. and Okla.

12. *Viola septemloba* LeConte. Acaulescent perennial, reproducing vegetatively by fragmentation of the horizontal rhizome; leaves spreading, with 3 to 6 narrow somewhat oblanceolate lateral lobes, thin, sometimes purple-tinged in spring, overall leaf shape orbicular to ovate; flowers blue-violet, on peduncles exceeding the leaves; lateral petals villous at base; fruits green, on erect peduncles; seed with inconspicuous caruncle. Wet lowland forests, often by streams, rare in extreme e. Tex., Mar.-Apr.; e. Tex. to s. Fla., n. to Va. and Tenn.

13. *Viola esculenta* Ell. Acaulescent perennial, reproducing vegetatively by fragmentation of the fleshy horizontal rhizome; leaves spreading, somewhat fleshy, with 4 to 6 broad palmately cut basal lobes; leaf lobes with parallel margins, not oblanceolate or obovate as in *V. septemloba*; flowers pale-violet; sepals with emarginate auricles; spurred petal slightly hairy; capsules cylindrical, green, borne on spreading peduncles. Wet open land in s.e. corner of Tex., Mar.-Apr.; Tex. to s. Fla., n. to s. Va. and n. Miss.

14. *Viola sororia* Willd. Acaulescent perennial, reproducing vegetatively by fragmentation of the thick horizontal rhizome; leaves spreading, broadly ovate to reniform, entire, pubescent on both surfaces with long hairs, sometimes villous; flowers varying in color from light-lilac to reddish-purple or dark-violet-purple; sepals with short broad ciliate auricles; peduncles of open flowers equaling or shorter than petioles; capsules large, ovoid, purple or purple-spotted, prostrate or buried in leaves; seeds buff to brown, ovoid, 1.75-2.5 mm. long. Woodland habitats of all sorts, sometimes a weed in cities, e. half of Tex., Mar.-Apr.; Tex. to n. Fla., n. to Que. and N.D.

15. *Viola villosa* Walt. Small acaulescent perennial, spreading from horizontal somewhat woody rhizomes; leaves forming flattened rosettes or nearly so, small, thick, from ovate to orbicular in shape, entire, heavily pubescent with long interwoven hairs (pilose); petioles short, about length of laminas; flowers violet or blue-violet; sepals short-auricled and ciliate; lower petals bearded; fruits green, on short prostrate or ascending peduncles; capsules to 1 cm. long; seeds blackish. Occasional in open rather dry deciduous forest in e. Tex., Mar.-Apr.; Tex. to n. Fla., n. to N.C., O., Ark. and s.e. Okla.

16. *Viola nephrophylla* Greene. Acaulescent perennial, spreading from horizontal somewhat fleshy rootstocks; leaves erect or ascending, orbicular to slightly reniform, entire, glabrous except for a scattering of tiny hairs on the upper surfaces of the lobes; petioles about 2 cm. long in summer; laminas of young leaves often purple on lower surface; flowers light-blue; sepals with short blunt glabrous auricles; spurred petal villous; capsules green, slightly ovoid, borne on erect peduncles above the leaves; seeds with pronounced caruncles. Open wet fields, rare in n.e. Tex., Mar.-May; n.e. Tex. to Que. and Ont., w. to N.D. and throughout Rocky Mts.

17. *Viola pratincola* Greene. Acaulescent perennial, reproducing vegetatively by fragmentation of the horizontal rhizome; leaves spreading, broadly ovate to cordate with acute apex, uniformly crenate from basal lobes to apex, completely glabrous; flowers blue-violet; sepals with marked auricles extending back about half the length of attached portion; lateral petals often with clusters of clavate hairs; cleistogenes on erect peduncles, sagittate in shape; capsules cylindrical, green. Occasional in open prairie, often beside railroads, sometimes a weed in towns and cities, e. half of Tex., reported from the Panhandle, Mar.-May; Tex. n. to Wisc., N.D. and w. to Colo.

18. *Viola Langloisii* Greene. Acaulescent perennial, reproducing vegetatively by fragmentation of the horizontal rhizome; leaves small, short, spreading, ovate, with cordate bases and slightly attenuate apices, with 10 to 14 teeth in upper third of each margin, completely glabrous; flowers blue-violet, borne on erect peduncles above the leaves; sepals narrow, slightly sagittate. River forests in e. Tex., especially in the s.e., Mar.-Apr.; cen. Tex., e. to cen. Fla., n. to n. Miss.

19. *Viola missouriensis* Greene. Acaulescent perennial, reproducing vegetatively by fragmentation of the thick horizontal rhizome; leaves large and numerous, often 20 to 30 produced from one crown, ovate to orbicular, with cordate bases, triangular at apex, with 0 to 6 widely spaced crenations, glabrous; flowers light-blue, borne on erect peduncles about same length as petioles; sepals broad, the auricles not pronounced; grading into *V. Langloisii*. Common in cen. and n.e. Tex. in river forests, Mar.-May; s. Tex. e. to Ark., n. to Minn. and Neb., w. to N.M.

groves on the Norias Division of the King Ranch in Kenedy Co. It possibly represents another species of *Xylosma*.

FAM. 128. TURNERACEAE DC.

TURNERA FAMILY

Herbs, shrubs or rarely trees; leaves alternate, petiolate, simple, toothed or serrate, often biglandular at base; stipules small or none; flowers perfect, axillary, solitary or fasciculate, often bibracteolate, calyx borne on hypanthium, 5-lobulate, the lobes imbricate, deciduous; petals 5, inserted on hypanthium, distinct, clawed, contorted; stamens 5, inserted on the hypanthium, the filaments free; styles 3, apically fringed; fruit a 1-celled 3-valvate many-seeded capsule.

About 120 species in 7 genera in tropical and subtropical America.

1. TURNERA L.

About 60 species mainly in tropical and subtropical America.

1. *Turnera diffusa* Willd. var. *aphrodisiaca* (Ward) Urban. DAMIANA, HIERBA DEL VENADO. Shrub to 2 m. tall, usually much smaller, the herbage aromatic; leaves alternate, petiolate, oblong-elliptic to elliptic-oblong, to 35 mm. long and 15 mm. wide, usually much smaller, cuneate at base, obtuse to subacute at apex, coarsely crenate-dentate to serrate, tomentose or merely pilose beneath, often glabrate above; flowers usually solitary, sessile, 8-12 mm. long; peduncle often adnate to the petiole; calyx with 5 narrow lobes, tomentose; petals yellow, obovate to spatulate, thin; capsule thin-walled, 4-5 mm. long; seeds with a membranaceous aril. On dry brushy hillsides along the Rio Grande in s. Tex., throughout the year; from throughout most of trop. Am.

Although long considered to be an aphrodisiac, its efficacy is dubious. In Mexico, according to Standley, the plant is used as a flavoring substance in liquors and for the making of Chinese tea.

FAM. 129. PASSIFLORACEAE JUSS.

PASSION-FLOWER FAMILY

Herbaceous or woody plants that climb by axillary simple tendrils; leaves alternate, simple (in ours), stipulate, lobed or unlobed, often with petiolar glands; peduncles axillary, jointed, commonly bracteate; flowers regular, bisexual, commonly 5-merous, often highly colored; sepals and petals imbricate, perigynous; floral cup usually with a corona; stamens monadelphous, the anthers versatile and 2-celled at anthesis; ovary mostly stipitate, 1-celled; styles usually 3; stigmas capitate to clavate or discoid; fruit a capsular berry; seeds arillate with straight embryo and fleshy endosperm.

An economically important tropical family composed of 12 genera with over 600 species.

1. PASSIFLORA L.¹³⁵

PASSION-FLOWER

Characters of the family; leaves usually palmately lobed; calyx tube campanulate to cylindrical; sepals fleshy or membranous, united at base; petals membranous, alternate with the sepals; corona of 1 to several series of distinct or more or less united filaments, rarely tubular; operculum various, borne within or below the corona; filaments of stamens united below to form a tube to sheath the long stalk of the ovary, distinct above; fruit baccate, indehiscent, globose to ovoid or rarely fusiform, containing a mucilaginous pulp that is often edible; seeds numerous, more or less compressed, variously reticulate, punctate or grooved.

About 500 species, mostly in the American tropics. Many produce edible fruits.

¹³⁵ Adapted mainly from E. P. Killip in Publ. Field Mus. Bot. 19:1-613. 1938.

1. Operculum plicate; bracts (when present) linear-subulate or setaceous, not involucrate (2)
1. Operculum not plicate, of various forms; bracts setaceous or foliaceous, scattered along the peduncle or involucrate (6)
- 2(1). Petiolar glands present; seeds reticulate (3)
2. Petiolar glands none; seeds with rugulose transverse ridges (4)
- 3(2). Petiolar glands sessile, more than 0.5 mm. in diameter; leaves much broader than long, the lobes narrow1. *P. tenuiloba*.
3. Petiolar glands usually stalked and less than 0.5 mm. in diameter; leaves usually longer than broad, the lobes broad2. *P. suberosa*.
- 4(2). Peduncles rather stout, provided with bracts that are often early-deciduous
.....5. *P. affinis*.
4. Peduncles very slender, bractless (5)
- 5(4). Outer corona filaments narrowly linear; lower leaf surface with raised reticulate veins, the apical leaf lobe usually triangular-ovate and mucronate; north of the Brownsville area3. *P. lutea*.
5. Outer corona filaments filiform; lower leaf surface without raised veins, the apical leaf lobe usually broadly rounded and retuse; confined to the Brownsville region4. *P. filipes*.
- 6(1). Bracts entire or only serrulate, forming an involucre near the base of the flower6. *P. incarnata*.
6. Bracts lacerate-dentate to bipinnatisect, the ultimate divisions usually gland-tipped7. *P. foetida* var.
gossypifolia.

1. *Passiflora tenuiloba* Engelm. Stem slender, subterete, glabrous or slightly pilosulous; stipules linear-setaceous, about 3 mm. long; petioles to 8 mm. long, bearing 2 sessile saucer-shaped glands at the extreme apex of the petiole or occasionally one on each of the lowermost lateral nerves close to their base, the glands sessile and 1-1.2 mm. in diameter; leaves deeply 3-lobed, subcordate at base, 3- to 5-nerved, strongly reticulate-veined, few-ocellate, coriaceous, sparsely or densely pilosulous above, glabrous beneath; leaf lobes linear to cuneate or oblong, often aristulate, the lateral lobes once- or twice-lobed and to 8 cm. long and 2 cm. wide, the middle lobe from one third to two thirds as long as the lateral lobes and entire to 3-lobed; peduncles solitary or in pairs, 3-7 mm. long, very slender, articulate at middle, finely pilosulous, at length glabrous; bracts none or early-deciduous; flowers about 2 cm. wide, greenish; sepals linear-lanceolate, 6-8 mm. long, 2 mm. wide, obtuse, hyaline-margined; petals none; corona filaments in 2 series, those of the outer narrowly linear and 3-4 mm. long, the inner ones filiform and 2 mm. long; operculum membranous, closely plicate, minutely denticulate at margin; limen annular, borne within 1 mm. of operculum; fruit globose, glabrous, black, 8-10 mm. in diameter; seeds ovate-oblong, 3-4 mm. long, 2-2.5 mm. wide, acute at both ends, reticulate at middle of each face, 5-sulcate at margin, the axis slightly curved. Prostrate or climbing on shrubs on limestone hills in s.w. Tex., Apr.-Oct.; from Tex., s. N.M. and n. Mex.

2. *Passiflora suberosa* L. Plant glabrous to densely pubescent, the lower portion of the stem corky; stipules linear-subulate, 6-8 mm. long; petioles 0.5-4 cm. long, biglandular, the glands usually less than 0.5 mm. in diameter and distinctly stipitate, rarely larger and subsessile, borne above middle of petiole; leaves highly variable in outline, entire to deeply 3-lobed, rounded or occasionally peltate at base, membranous or subcoriaceous, sometimes ocellate beneath; leaf lobes narrowly linear to broadly ovate, suberect or widely divergent, acute or obtuse; flowers 1-3 cm. wide, solitary or in pairs in the axils of the leaves, occasionally in leafy axillary racemes; bracts minute, setaceous, soon deciduous; sepals ovate-lanceolate, subobtuse, greenish-yellow; petals none; corona filaments in 2 series, filiform, the outer recurved, white, yellow at apex and purple below, those of the inner series capitellate; operculum membranous, plicate, minutely fimbriate, white, the margin incurved; limen annular; fruit globose to ovoid, dark-purple or black, glaucous

when young, 6-15 mm. in diameter; seeds flattened, slightly curved, abruptly acuminate at apex, tapering at base, 3-4 mm. long, 2 mm. wide, coarsely reticulate. In palm groves and thickets in extreme s. Tex., June-Oct.; from s. Fla. and s. Tex. to n. S.A. and W.I., introd. into Old World.

3. *Passiflora lutea* L. Plant glabrous or sparingly pilosulous; stipules setaceous, 3-5 mm. long, deciduous; petioles to 5 cm. long, glandless; leaves usually much wider than long, 3-7 cm. long, 4-10 cm. wide, 3-lobed usually from one quarter to one third their length, rounded to subcordate or subtruncate at base, 3-nerved, closely and usually inconspicuously reticulate-veined, membranous, rarely subcoriaceous; leaf lobes broadly triangular-ovate, rounded or obtuse, rarely acutish, often mucronulate; peduncles solitary or in pairs, 1.5-4 cm. long, very slender; bracts none; flowers 1-2 cm. wide; calyx tube patelliform; sepals linear-oblong, 5-10 mm. long, 2-3 mm. wide, obtuse, pale-green; petals linear, 3-5 mm. long, about 1 mm. wide, acutish, white; corona filaments in 2 series, the outer ones about 30, narrowly linear or almost filiform, 5-10 mm. long, radiate, greenish-white, the inner narrowly liguliform, 1.5-2.5 mm. long, slightly thickened toward apex, white above, pink-tinged at base; operculum membranous, plicate, erect, white at margin, pale-pink at base; nectar ring a low ridge; limen cupuliform, fleshy; fruit globose-ovoid, glabrous, about 15 mm. long and 1 cm. in diameter; seeds broadly obcordate to suborbicular, 4.5-5 mm. long, 3 mm. wide, transversely sulcate with 6 or 7 grooves, the ridges strongly rugulose. In shade of low moist woods mainly in cen. and e. Tex., May-Aug.; from Pa. to Ill. and Kan., s. to Fla. and Tex.

This species is distinguished from *P. filipes* by the thicker filaments of the outer corona, and by thicker, more deeply lobed leaves, the reticulate venation of which is quite evident. Most of our material is referable to var. *glabriflora* Fern., characterized by having the calyx, leaves and stems quite glabrous.

4. *Passiflora filipes* Benth. Plant slender, glabrous throughout; stem terete; stipules linear-lanceolate, 2-4 mm. long, falcate, acuminate; petioles 1-2 cm. long, glandless; leaves 1-4 cm. long, 2-6 cm. wide, 3-lobed at apex, rounded at base, 3-nerved, dark-green above, slightly glaucescent beneath; leaf lobes nearly equal, obtuse or slightly acuminate; peduncles very slender, 4-6 cm. long, diverging at nearly right angles to the stem; bracts none; flowers small, 8-15 mm. wide, yellowish-green or greenish-white; sepals lanceolate to linear-lanceolate, 6-9 mm. long, 2 mm. wide, acutish; petals narrowly linear, 3-4 mm. long, 1.5 mm. wide; corona filaments in 2 series, filiform, the outer equaling the petals, the inner shorter; operculum membranous, plicate, incurved; limen annular, close to the gynophore; fruit globose, glabrous, 5-7 mm. in diameter; seeds slightly flattened, obovate to obcordate, 4 mm. long, 2.5-3 mm. wide, transversely sulcate with 3 or 4 broken ridges. In palm groves and thickets in extreme s. Tex., Mar.-Oct.; from Tex. to Nic.; also Venez.

5. *Passiflora affinis* Engelm. Plant glabrous throughout; stipules linear-subulate, 1.5-2 mm. long, falcate, deciduous; petioles 1-3.5 cm. long, slender, glandless; leaves 2-10 cm. long, 3-14 cm. wide, usually lobed from a half to two thirds their length, rarely about one third, cordulate or subtruncate at base, 3-nerved, minutely ocellate beneath, membranous or subcoriaceous; leaf lobes variable, oblanceolate to oblong or ovate, rounded or obtuse, mucronulate, the middle lobe slightly longer than the lateral lobes, the latter sometimes bilobulate; peduncles solitary or in pairs, 1-3 cm. long; bracts setaceous, 1-3 mm. long, remote in upper half of peduncle, subpersistent; flowers 2-2.5 cm. wide, greenish-yellow; sepals oblong-lanceolate, 1-1.2 cm. long, 2-3 mm. wide, obtuse; petals linear, 6-8 mm. long, 1.5-2 mm. wide; corona filaments in 2 series, the outer filiform, 7-9 mm. long, knobbed at apex, the inner filiform, 1.5-2.5 mm. long; operculum membranous, closely plicate, incurved; limen annular; fruit subglobose, glabrous, 8-10 mm. long, purplish-black; seeds obcordate, about 3 mm. long and 2 mm. wide, transversely sulcate, the grooves 6 or 7. On limestone on the Edwards Plateau, June-Aug.; also n. Mex.

This species differs from *P. lutea*, which it closely resembles, in having bracts on the peduncles and in the presence of distinct knobs at the tips of the outer corona filaments.

6. *Passiflora incarnata* L. MAYPOW, PASIONARIA. Plant glabrous or usually finely pilosulous; stem terete, the younger portion angular; stipules setaceous, 2-3 mm. long, very early-deciduous; petioles to 8 cm. long, biglandular at apex, the sessile glands suborbicular; leaves 6-15 cm. along midnerve, 5-12 cm. along lateral nerves, 7-15 cm. between apices of lateral lobes, 3-lobed from three quarters to four fifths their length, cordulate,

finely serrate, 3-nerved, membranous, dark-green above, glaucescent beneath; leaf lobes ovate-lanceolate or oblong-lanceolate, 2-5 cm. wide, acute or acuminate, the middle lobe narrowed at base, rarely with the lateral lobes bilobate; peduncles to 1 dm. long, stout; bracts spatulate to oblong, 4-7 mm. long, 2.5-4 mm. wide, obtuse to acute, minutely glandular-serrulate toward apex, conspicuously biglandular at base, borne about 5 mm. below flower; flowers to 7 cm. wide; calyx tube short-campanulate; sepals lanceolate-oblong, 2-3 cm. long, about 1 cm. wide, white or pale-lavender, obtuse, cucullate at apex, slightly carinate, the keel terminating in an awn 2-3 mm. long; petals subequal to sepals, obtuse, white or pale-lavender; corona filaments in several series, purple or pink, rarely pure white, those of the outer 2 series filiform, 1.5-2 cm. long, crispate at apex, slightly enlarged at base, radiate, those of the succeeding 3 series capillary, about 2 mm. long, radiate or suberect, the innermost series membranous at base, filamentose, the filaments about 4 mm. long, capitellate; operculum membranous, about 2 mm. long, incurved, fimbriate; nectar ring a low ridge halfway between the operculum and gynophore; limen cupuliform, closely surrounding base of gynophore, crenulate; ovary ovoid, densely brownish or whitish-velutinous-tomentose; fruit ovoid to subglobose, to 5 cm. long, orange-yellow when ripe, edible; seeds obovate to nearly orbiculate, 4-5 mm. long, 3-4 mm. wide, truncate at apex, reticulate. In old fields, along roadsides and streams, and in and on the edge of open woods in the e. third of Tex., Apr.-Aug.; from Va. to Mo., s. to Fla. and Tex.; also in Berm.; introd. farther n. in U.S.

This is our only species with edible fruit.

7. *Passiflora foetida* L. var. *gossypifolia* (Hamilt.) Mast. CORONA DE CRISTO. Plant villosulous or hirsutulous throughout, often viscous, the indument grayish, brownish or yellowish-brown, averaging not more than 1.5 mm. long; leaves hastate, averaging 5 cm. long and 5 cm. at greatest width, undulate or crenate-serrulate, the basal lobes usually semicircular in outline and sometimes abruptly narrowed to an obtuse point; bracts 2-3 cm. long, bipinnatisect or tripinnatisect, the ultimate filiform segments gland-tipped, straight or nearly so, not closely interwoven; flowers 2-5 cm. wide, white to purplish; sepals ovate-oblong to ovate-lanceolate, awned dorsally just below apex; petals oblong to oblong-lanceolate or oblong-spatulate, slightly shorter than sepals; corona filaments in several series, those of the 2 outer series filiform, about 1 cm. long, the others capillary, 1-2 mm. long; operculum membranous, erect, denticulate; ovary sparingly to densely pilosulous, the hairs persisting in fruit; fruit 2-2.5 cm. in diameter, yellow or greenish-yellow, red-spotted; seeds ovate-cuneiform, about 5 mm. long and 2.5 mm. wide, obscurely tridentate at apex, coarsely reticulate at the center of each face. In thickets and among weeds in sand, saline depressions and along ditches in s. Tex., Apr.-Oct.; from Tex. through Mex. and C.A. to n. S.A.; also W.I.

FAM. 130. LOASACEAE DUM.¹³⁶

STICK-LEAF FAMILY

Annual or perennial herbs (to woody) with barbed or sometimes stinging hairs; leaves alternate (or opposite), entire or lobed; flowers regular, bisexual; sepals persistent; corolla apetalous to sympetalous, sometimes with petaloid staminodia alternate with the petals; stamens 5 to many (sometimes fascicled); filaments narrow to petaloid; style 1, usually persistent; ovary inferior, 1-locular with 1 to 5 placentae; ovules 1 to many; fruit dry, dehiscent and many-seeded (capsule) or indehiscent and 1-seeded (achene); seeds variable; embryo straight or somewhat hooked.

About 200 species in 14 genera in temperate and tropical America and 1 genus of 2 species in the Old World.

1. Stamens 5; connective inflated and exceeding the pollen sacs; fruit indehiscent, 1-seeded; suffrutescent; hairs stinging 1. *Cevallia*, p. 1083.
1. Stamens numerous; anthers with inconspicuous connective; fruit dehiscent, 2- to many-seeded; annual or perennial; hairs scabrous, not stinging (2)

¹³⁶ Contributed by Henry J. Thompson and Joyce Roberts Zavortink.

- 2(1). Leaf blades orbicular, mostly cordate, with the petioles at least as long as the blade; pedicels elongating in fruit; seeds minute2. *Eucnide*, p. 1083.
2. Leaf blades ovate to oblanceolate, never cordate, sessile or with a petiole much shorter than the blade; pedicels not elongating in fruit; seeds 1.5-4 mm. long ...3. *Mentzelia*, p. 1083.

1. CEVALLIA LAG.

A monotypic genus with the characteristics of the species.

1. *Cevallia sinuata* Lag. Plants suffrutescent, to 6 dm. tall; leaves and stems tomentose and armed with long stinging hairs; leaves sinuate to pinnatifid, sessile or nearly so; flowers in tight heads on long peduncles borne opposite the leaves, opening in the morning; sepals and petals similar, 5-8 mm. long, plumose, yellow on the inner surface; stamens 5; filaments short, thick, the connective extending beyond the anthers as a hollow inflated appendage; fruit indehiscent, with only one seed; chromosomes $n=13$. Open areas, often along roadsides, on various coarse substrates, in w. half of the state and common along the Rio Grande, June-Oct.; w. to s.e. Ariz. and n. Mex.

2. EUCNIDE ZUCC. ROCK-NETTLE

Eleven species in southwestern United States, Mexico and Guatemala.

1. *Eucnide bartonioides* Zucc. Annual or herbaceous perennial, more or less woody at base; leaves alternate, with petioles 4-14 cm. long, orbicular to cordate, with crenate or dentate margins; flowers 5-merous, opening in late afternoon; calyx lobes lanceolate, 5-20 mm. long; corolla sympetalous; petals obovate, light-yellow, 1-4 cm. long; stamens numerous, filiform, (15-) 25-50 mm. long; ovary inferior, 1-celled with 5 placentae; style (13-) 30-55 mm. long; capsules globular to obovoid, 5-13 mm. long, 5-8 mm. wide; pedicels elongating to 15 cm. or more in fruit; seeds numerous, minute, less than 0.5 mm. long, oblong, grooved or ribbed longitudinally; chromosomes $n=21$. On limestone bluffs or gravelly slopes in w. Edwards Plateau and the Trans-Pecos, May-Aug.; s. in Mex. to S.L.P.

3. MENTZELIA L.

Perennial or annual; hairs barbed but not stinging; leaves lobed or entire, petiolate or sessile; flowers solitary and axillary or in terminal bracteate more or less cymose inflorescences; perianth 5-merous, usually 2-seriate; stamens few to many; filaments filiform or dilated; staminodes present or absent; style filiform; ovary with 3 to 5 placentae; ovules few to many; capsules variable in size and shape, sessile to short-pedicellate; seeds irregularly angled, flattened or oblong, the surface smooth, tuberculate or wrinkled, sometimes striate.

About 60 species in temperate and tropical America, mostly in southwestern United States and Mexico. *Mentzelia pumila* (Nutt.) T.&G. has been reported from Texas but we have seen no material from the state. It is very dubious that this far-western species would occur in Texas.

1. Seeds pendulous, not winged; petals 5 (2)
1. Seeds horizontal, winged; petals more than 5 (Sect. *Bartonia*) (7)
- 2(1). Seeds irregularly angled or somewhat prismatic; petals less than 5 mm. long (Sect. *Trachyphytum*) (3)
2. Seeds oblong or flattened and pyriform; flowers with petals longer than 5 mm. (Sect. *Mentzelia*) (4)

- 3(2). Bracts usually entire, not white at base; axillary capsules usually recurved to be at least 90°; seed surface with large pointed papillae . . . 1. *M. albicaulis*.
3. Bracts usually lobed, white at base; axillary capsules usually erect or only slightly curved to 45°; seed surface with minute pointed papillae 2. *M. montana*.
- 4(2). Seeds oblong, more or less 3-sided; capsules becoming hard and woody 3. *M. oligosperma*.
4. Seeds flattened and pyriform; capsules never hard and woody (5)
- 5(4). Petals 10-16 mm. long; styles 10-12 mm. long; stamens of 2 distinct lengths, inner 5-9 mm. long, outer 10-14 mm. long 4. *M. incisa*.
5. Petals less than 12 mm. long; stamens more or less equal in length (6)
- 6(5). Petals 6-8 mm. long; styles and stamens 4-5 mm. long 5. *M. texana*.
6. Petals 9-12 mm. long; styles 7-10 mm. long; stamens 7-9 mm. long 6. *M. Lindheimeri*.
- 7(1). Petals over 4 cm. long; styles 5-6 cm. long; stamens 3-5 cm. long, forming a loose cylindrical cluster around style at anthesis 7. *M. decapetala*.
7. Not as above (8)
- 8(7). Petals 6-11 mm. long; sepals 3-6 mm. long; capsules long-cylindrical, 20-30 mm. long 8. *M. albescens*.
8. Flowers large or small but not with above combination; if sepals and petals are small then capsules are less than 13 mm. long (9)
- 9(8). Leaves with very narrow rachis, entire or pectinately lobed (10)
9. Leaves with medium to broad rachis, dentate or with short lobes, never entire or pectinate (11)
- 10(9). Petals white, linear; leaves pectinately lobed 9. *M. humilis*.
10. Petals yellow, broader; leaves mostly entire; Hudspeth County only 10. *M. saxicola*.
- 11(9). Some fertile stamens with broad filaments (12)
11. All fertile stamens with narrow filaments (13)
- 12(11). Plants usually taller than 3 dm., open, not compact; leaf rachis less than 6 mm. wide, the margins lobed with lobes as long as or longer than the width of the rachis 11. *M. multiflora*.
12. Plants low and much-branched from base, compact, 1-2 dm. tall; leaf rachis broad, 6-12 mm. wide, the margins dentate or with short round lobes that are shorter than width of the rachis 12. *M. mexicana*.
- 13(11). Petals yellow; cauline leaves broad-based, sessile and more or less clasping 13. *M. Reverchonii*.
13. Petals white; cauline leaves narrow, base not broad or clasping (14)
- 14(13). Petals 25-40 mm. long; styles 12-20 mm. long; bracts linear-lanceolate, lacinate 14. *M. nuda*.
14. Petals 11-25 mm. long; styles 7-12 mm. long; bracts linear, entire or sometimes few-toothed 15. *M. strictissima*.

1. *Mentzelia albicaulis* (Hook.) T.&G. Rosette-forming annual, erect or spreading; lower leaves linear, usually deeply lobed; upper leaves linear to ovate-lanceolate, usually lobed, uppermost sometimes entire; floral bracts usually linear-lanceolate, entire or somewhat angular; flowers opening in early morning; calyx lobes 2-4 mm. long; petals ovate, yellow, 3-5 mm. long; stamens many, 3-5 mm. long; style 3-5 mm. long; capsules cylindrical, narrowed at base, erect or the first-formed capsule sometimes recurved, 15-30 mm. long; seeds 20 to 30 per capsule, irregularly angled, slightly tessellate, the surface with large pointed papillae; chromosomes $n=36$. On gravelly slopes and along roadsides, in extreme w. Tex., Apr.-May; from Neb., w. to Calif., n. to B.C., s. into Baja Calif. and n. Mex.

2. *Mentzelia montana* (Davids.) Davids. Rosette-forming annual, erect or somewhat spreading; lower leaves linear, lobed or entire; upper leaves linear to ovate-lanceolate, entire or few-lobed; floral bracts narrow and linear, lobed or angular, with a white spot at base; flowers opening in early morning; calyx lobes 2-4 mm. long; petals yellow, obovate, 2-5 mm. long; stamens 20 to 40, 2-4 mm. long; style 2-4 mm. long; capsules cylindrical, narrowed at base, erect or occasionally slightly curved, 8-20 mm. long; seeds irregularly angled or somewhat prismatic, tan or sometimes slightly tessellate, about 35 per capsule, the surface with very small pointed papillae; chromosomes $n=18$. Under evergreen oaks or mesquite, or in dry streambeds with cottonwoods, only in Culberson Co., Apr.-May; w. to Calif.

3. *Mentzelia oligosperma* Sims. STICK-LEAF, CHICKEN-THIEF, PEGAJOSA. Rounded to matted semiwoody perennial with enlarged roots; leaves sessile or short-petiolate, ovate to distinctly trilobed with irregularly toothed margins; flowers opening in early morning; calyx lobes lanceolate, 6-8 mm. long; petals orange (salmon), ovate, 9-13 mm. long; stamens 25 to 35, subequal, 6-10 mm. long; filaments all narrow; style 7-10 mm. long; capsules woody, sessile, cylindrical, often curved, 7-13 mm. long; seeds oblong, more or less 3-sided, 2 or 3 per capsule; chromosomes $n=11$. On limestone bluffs in wooded areas but also on shell debris as in Aransas Co., and on sandy or clay soils and occasionally in ruderal areas, generally throughout Tex., late May-Sept.; from n. Ark., Mo. and S.D. to Colo.

4. *Mentzelia incisa* Urban & Gilg. Perennial, to 6 dm. tall, with several semiwoody stems from an enlarged root; leaves petiolate or subsessile, ovate to more or less trilobed, margins irregularly dentate or crenate; time of flower-opening unknown; calyx lobes lanceolate, 8-11 mm. long; petals yellow to orange, obovate, 10-16 mm. long; stamens 30 to 40, the outer 5 to 10 about 10-14 mm. long and with filaments slightly dilated at base, inner whorl 5-9 mm. long with filaments all narrow; style 10-12 mm. long; capsules subcylindrical to obconical, 10-15 mm. long, usually pedicellate and attenuated at base; seeds flattened, pyriform, about 5 to 8 per capsule. On gravelly slopes, igneous soil along streams in s. Tex., Mar.-Nov.; also Mex.

5. *Mentzelia texana* Urban & Gilg. Perennial to 12 dm. tall; leaves petiolate, ovate to trilobed, width irregularly dentate margins; flowers opening in early morning; calyx lobes 4-5 mm. long; petals yellow, obovate, 6-8 mm. long; stamens about 25; filaments all narrow, 4-5 mm. long; styles 4-5 mm. long; capsules conical to cylindrical, sessile or somewhat attenuated at base to a very short pedicel, 10-20 mm. long; seeds flattened, pyriform, 6 to 8 per capsule. *M. asperula* Woot. & Standl. On canyon slopes and edges of oak woodland in s. and s.w. Tex., Sept.-Nov.; also Mex. (Pue.)

6. *Mentzelia Lindheimeri* Urban & Gilg. Perennial to 6 dm. tall, with several semiwoody stems from an enlarged root; leaves petiolate or subsessile, ovate to more or less trilobed, margins irregularly dentate or crenate; time of flower-opening unknown; calyx lobes lanceolate, 6-9 mm. long; petals yellow to orange, obovate, 8-12 mm. long; stamens 30 to 45, subequal, 7-9 mm. long; style 7-10 mm. long; capsules subcylindrical, 10-14 mm. long, usually pedicellate and attenuated at base; seeds flattened, pyriform, about 4 to 8 per capsule. Gravelly slopes in s. Tex., Mar.-Nov.; also Mex.

7. *Mentzelia decapetala* (Pursh) Urban & Gilg. Herbaceous perennial with stems often 1 m. tall; rosette leaves oblanceolate, sinuate; cauline leaves oblanceolate, coarsely toothed; bracts sessile, lacinate, the uppermost borne on the side of the capsule; flowers large, opening about 1 hour after sunset; calyx lobes 2.5-4 cm. long; petals 10, white, 4-8 cm. long; stamens numerous, 3-5 cm. long, at anthesis forming a loose cylindrical cluster around the style; style 5-6 cm. long; capsules 3-4.5 cm. long; seeds flattened, oval in outline, 3 mm. long, with a wing 0.5 mm. wide; chromosomes $n=11$. *M. ornata* T. & G., *Bartonia decapetala* Pursh. Disturbed places in prairies, gravel slopes and roadbanks, in n.w. Tex., mostly in the Panhandle, June-Aug.; northw. e. of the Rockies into s. Alta. and Sask.

8. *Mentzelia albescens* (Gill. & Arn.) Griseb. Herbaceous perennial, the stems strictly branched, erect, 3-6 dm. tall; lower leaves linear-lanceolate to oblanceolate, coarsely dentate to lobed; cauline leaves linear-lanceolate to ovate-lanceolate, toothed or lobed; bracts linear to lanceolate, entire or slightly toothed or more or less lobed at base; flowers opening in late afternoon; calyx lobes 3-6 mm. long; petals light-yellow, more or less

ovate, 6-11 mm. long; stamens numerous, most fertile anthers with narrow filaments, few outer ones with broadened filaments, 3-6 mm. long; style 4-6 mm. long; capsules cylindrical, 20-30 mm. long; seeds flattened, oval, 2.5-3.5 mm. long, with a wing to 1 mm. wide; chromosomes $n=11$. On open disturbed sites, often ruderal, in cen. and w. Tex., May-Aug.; Colo., Kan., Mo., Okla., s. into Chih.; also Chile and Arg.

9. *Mentzelia humilis* (Urban & Gilg) Darl. Herbaceous perennial with stem 2-6 dm. tall; leaves linear to linear-lanceolate, with very narrow rachis, pectinately lobed, the lobes usually long but sometimes short; bracts linear and entire; flowers opening in late afternoon; calyx lobes 6-11 mm. long; petals white, linear, 9-23 mm. long; stamens numerous, most fertile stamens with narrow filaments, occasionally a few with somewhat broadened filaments, 9-15 mm. long; style 6-13 mm.; capsules globular or cup-shaped, 6-13 mm. long, 4-6 mm. wide; seeds flattened, oval, 3-4 mm. long, with a wing about 1 mm. wide; chromosomes $n=10$. On gypsum soils in w. Tex. (Culberson, Loving and Ward cos.), June-Oct.; also N.M.

10. *Mentzelia saxicola* Thomps. & Zavortink. Herbaceous perennial, to 4 dm. tall; rosette leaves linear, entire or with very short lobes; cauline leaves linear, usually entire or with short lobes or toothed; bracts linear, entire; flowers opening in late afternoon; calyx lobes 5-8 mm. long; petals yellow, ovate, 9-12 mm. long; stamens numerous, most fertile stamens with narrow filaments, a few with dilated filaments, 6-8 mm. long; style 6-8 mm. long; capsules globular or cup-shaped, 7-10 mm. long; seeds flattened, oval, 1.5-2 mm. long, with a wing 1 mm. wide; chromosomes $n=10$. On gypsum soils and rocky hills in Presidio, Hudspeth and El Paso cos. only, July-Oct.; endemic.

11. *Mentzelia multiflora* (Nutt.) Gray. Herbaceous perennial; stems 2-8 dm. tall, several- to many-branched; leaves linear-lanceolate, with narrow to medium rachis, usually with long lobes; bracts linear, entire to somewhat lobed; flowers opening in late afternoon; calyx lobes 6-9 mm. long; petals yellow, obovate, 7-25 mm. long; stamens numerous, 5-10 mm. long, outer fertile stamens with broad filaments grading to inner stamens with narrow filaments; style 6-10 mm. long; capsules cylindrical to cup-shaped, 8-24 mm. long; seeds flattened, oval, 1.5-3 mm. long, with a wing 0.5-1 mm. wide; chromosomes $n=9$. On disturbed sites of various substrates, w. Tex., Mar.-Sept.; in most of w. U.S. and Mex.

12. *Mentzelia mexicana* Thomps. & Zavortink. Herbaceous perennial with stems 1-2 dm. tall, compact and much-branched from the base; lower leaves more or less lanceolate, with broad rachis 6-12 mm. wide, margins dentate or with short round lobes shorter than the width of the rachis, upper leaves similar but smaller; bracts linear and entire; time of flower-opening not known; calyx lobes triangular to lanceolate, 6-8 mm. long; petals yellow, ovate-lanceolate, 8-15 mm. long and 2-5 mm. wide; stamens numerous, 5 mm. (inner) to 10 mm. (outer) long, some filaments dilated to 2 mm. wide; style 6-10 mm. long; capsules cup-shaped, 5-15 mm. long; seeds flattened, oval, 1.8-2 mm. long, with a wing to 1.2 mm. wide; chromosome number not known. On clay soils or rocky slopes, 2,000-4,000 ft. alt., known in Tex. from Brewster Co. only, Mar.-Sept.; also Coah. and e. Chih.

13. *Mentzelia Reverchonii* (Urban & Gilg) Thomps. & Zavortink. Herbaceous perennial with stems to 1 m. tall; rosette leaves linear-lanceolate, with broad rachis and short blunt lobes; cauline leaves lanceolate to ovate-lanceolate, shallowly lobed to coarsely or finely toothed; uppermost leaves with broad somewhat clasping base; bracts linear to lanceolate, entire to toothed or lacinate; time of flower-opening unknown; calyx lobes 10-12 mm. long; petals yellow, spatulate, 15-30 mm. long; stamens numerous, fertile stamens with narrow filaments, some narrow staminodes present, from 4 mm. (inner) to 20 mm. (outer) long; style 11-17 mm. long; capsules cylindrical, 15-30 mm. long; seeds flattened, oval, 2-3 mm. long, with a wing 0.5-1 mm. wide. *M. nuda* of auth., *M. Wrightii* of auth. On gravelly and limestone soils, throughout most of Tex. except the extreme e. portion, May-Sept.; s.e. Colo., s.w. Okla., e. N.M. into n. Mex.

14. *Mentzelia nuda* (Pursh) T.&G. Herbaceous perennial, strictly branched, to 1 m. tall; leaves linear-lanceolate, bluntly dentate to sharply toothed, very scabrous; bracts linear-lanceolate, lacinate; flowers opening in late afternoon; calyx lobes 10-19 mm. long; petals white, linear-oblongate, 25-40 mm. long; stamens numerous, fertile stamens

with narrow filaments, most staminodia narrow or a few slightly dilated but not broad, from 4 mm. (inner) to 25 mm. (outer) long; style 12-20 mm. long; capsules cylindrical, 18-30 mm. long; seeds flattened, oval, 1.5-2.5 long, with a wing about 1 mm. wide; chromosomes $n=10$. *M. stricta* (Osterh.) Jeffs & Little. On open sites in grassland and prairies usually on sandy soils, throughout cen. Tex., from the Panhandle to the Rio Grande Valley, June-Oct.; e. of the Rocky Mts. from Mont. and S.D., s. into n. N.M.

15. *Mentzelia strictissima* (Woot. & Standl.) Darl. Herbaceous perennial, strictly branched, to 9 dm. tall; leaves linear-lanceolate, irregularly dentate to finely toothed, scabrous; bracts linear, entire or somewhat toothed at base; flowers opening in late afternoon; calyx lobes 8-12 mm. long; petals white, linear-oblongate, 11-25 mm. long; stamens numerous, from 4 mm. (inner) to 20 mm. (outer) long; fertile stamens with narrow filaments, most staminodia narrow, a few slightly dilated; style 7-12 mm. long; capsules cylindrical or subcylindrical, 13-18 mm. long; seeds flattened, oval, 1.5-2.5 mm. long, with a wing to 1 mm. wide; chromosomes $n=10$. On open sites in grassland and prairies usually on sandy soils, in w. Tex., May-Sept.; also e. N.M.

FAM. 131. CACTACEAE JUSS.¹³⁷

CACTUS FAMILY

Stems succulent, 0 to many ribs; tubercles separate to coalescent; leaves exceedingly small, usually none in adult plants; areoles usually bearing spines; flowers epigynous; floral tube bearing usually areoles and often scale leaves, the part above the inferior ovary from almost obsolete to elongate and tubular; scale leaves of the tube shading upward into sepaloid structures and these into petaloid structures; stamens numerous; carpels cyclic, 3 to 20; stigmas separate; style 1; ovary 1-chambered; ovules numerous, on laminar placentae that are as numerous as the carpels or stigmas and which protrude from the walls, usually campylotropous; hilum basal or appearing "lateral."

1,000 or more species from Canada to southern South America.

1. Areoles bearing glochids (barbed bristles) as well as spines; young stem with a slender fleshy leaf below each areole; floral tube barely developed above the ovary; stems composed of series of cylindroid or flattened joints, not ribbed; flower within or on the edge of the areole1. *Opuntia*, p. 1088.
1. Areoles *not* bearing glochids; stem leafless; floral tube often developed into a deep cup or a tube above the ovary (2)
 - 2(1). Flowers nearly always on stem areas 1 to several years old, usually clearly below the apex of the stem or branch; seed longer than broad; hilum obviously basal or rarely oblique (3)
 2. Flowers on the new growth of the season at the apex of the stem or branch in a felted area merging directly or through an isthmus with the new spiniferous areole; cotyledons accumbent (5).
 - 3(2). Stems *not* ribbed, with independent tubercles; flower bud in a special areole between tubercles, *not* associated with the spiniferous areole on the tubercle; cotyledons accumbent4. *Mammillaria*, p. 1100.
 3. Stems ribbed; flower bud *either* within the spiniferous areole *or* bursting through the epidermis just above it; ovary bearing scale leaves or spines; cotyledons incumbent (4)

¹³⁷ Contributed by Lyman Benson. Most of the voluminous synonymy is omitted here, but it may be found in *The Cacti of the United States and Canada* by Lyman Benson, ined., and by him in an abridged form in C. L. Lundell, *Flora of Texas II*: 221-317. 1969. The research underlying preparation of the manuscript on the Cactaceae was supported by several research grants from the Claremont Graduate School, by one for 1950 from the Society of Sigma Xi, and by three grants from the National Science Foundation covering the periods from 1956-1959, 1960-1964, 1965-1967. This aid is acknowledged with gratitude.

- 4(3). Flower within at least the edge of a mature spine-bearing areole; stem length 15 to 100 times the diameter; embryo curved 2. *Cereus*, p. 1094.
4. Flower bud bursting through the epidermis just above a mature spine-bearing areole; stem length 1 to 5 or 10 times the diameter; embryo nearly straight 3. *Echinocereus*, p. 1095.
- 5(2). Areoles of the mature plant bearing spines (6)
5. Areoles of the *mature* plant *not* bearing spines, with tufts of hair; hilum obviously basal except in the single species of *Echinocactus* appearing under this lead (12)
- 6(5). Flower-bearing portion of the areole adjacent to and merging with the spine-bearing portion (7)
6. Flower-bearing portion of the areole (except on juvenile stems) distant from the spine-bearing portion, the flower or fruit standing apart from the spine cluster at the end of a narrow felted and usually linelike groove extending to the base of the tubercle (10)
- 7(6). Flower-bearing portion of the areole narrow, 3 to several times as long as broad, extending along as much as half or more of the tubercle; ovary with a few scale leaves, the areoles *not* bearing axillary hairs; seed longer than broad, the hilum obviously basal 9. *Thelocactus*, p. 1105.
7. Flower-bearing portion of the areole broad, nearly circular to rectangular or irregular (8)
- 8(7). Stems *not* ribbed, the tubercles separate; ovary with few or no scales, the surface never obscured by hairs; seeds broader than long, the hilum appearing "lateral;" fruit thin-walled, bright-red; floral cup deciduous . . 8. *Epithelantha*, p. 1104.
8. Stems strongly ribbed; ovary with numerous scale leaves; fruit thick-walled; floral cup persistent (9)
- 9(8). Fruit fleshy at maturity, the areoles *not* woolly; sepaloid perianth parts *not* spinose or aristate; seed longer than broad, the hilum obviously basal or "sub-basal" or sometimes "diagonal" 6. *Ferocactus*, p. 1102.
9. Fruit (at least in the spiny species) dry at maturity, the areoles bearing long woolly hairs that obscure the fruit; sepaloid perianth parts apically spinose or aristate; seed broader than long, the hilum appearing "lateral" 7. *Echinocactus*, p. 1103.
- 10(6). Spines (either the principal central or the lower radial or both) hooked; tubercles of *mature* plants coalescent basally into ribs; ovary bearing one to many scale leaves; fruit green to red, indehiscent 11. *Ancistrocactus*, p. 1107.
10. Spines all straight or curved, *none* hooked [except in *Coryphantha Scheeri* var. *uncinata* (rare, near El Paso)]; tubercles separate, *not* coalescent (11)
- 11(10). Fruit tan or green, dry, opening *either* lengthwise *or* diagonally at the base; ovary bearing a few (up to 20) membranous scales 10. *Neolloydia*, p. 1106.
11. Fruit green or red, fleshy but very thin-walled, indehiscent; ovary *not* bearing scale leaves (except a few in *Coryphantha macromeris*) . . 12. *Coryphantha*, p. 1108.
- 12(5). Tubercles *not* coalescent, flattened and strongly roughened and fissured on the upper sides; fruit *not* bearing scale leaves; petals pink to magenta or white 13. *Ariocarpus*, p. 1113.
12. Tubercles coalescent into ribs, smooth (13)
- 13(12). Stem ribs *not* scaly; ovary *not* bearing scale leaves; petals pink or tinged with pink 5. *Lophophora*, p. 1102.
13. Stem ribs covered with radiating white hairy scales; ovary bearing brown imbricated scarious scale leaves; petals yellow but the bases red 7. *Echinocactus*, p. 1103.

1. OPUNTIA MILL.

PRICKLY PEAR. CHOLLA

Stems of series composed of cylindroidal or flattened joints; ribs none, the tubercles separate or none; leaves cylindroidal, acicular or subulate, ephemeral; spines commonly

1 to 10 per areole; glochids barbed; flower within the spine-bearing areole; floral tube above the ovary very short, deciduous; fruit fleshy or dry, indehiscent; seeds discoid; cotyledons incumbent, foliaceous.

Many species in the Western Hemisphere, the number uncertain.

1. Joints of the stem cylindroidal; epidermis of the spine separating completely or only apically into a thin paperlike sheath; glochids *usually but not necessarily* (see leads 2 below) small and inconsequential (Subg. 1. *Cylindropuntia*, chollas) (2)
1. Joints of the stem flattened; epidermis of the spine not separating into a sheath; glochids usually but *not* always large, well-developed, barbed and effective (Subg. 2. *Opuntia*, prickly pears) (6)
- 2(1). Spine with the epidermis separating into a sheath at only the extreme apex, at least basally flattened, with rough crossbands of papillae; glochids (especially on underground stems and often on fruits) large and strongly barbed; joints clavate; plant forming a mat 5. *O. Schottii*.
2. Spine with the entire epidermis separating into a thin and paperlike sheath, slender, *not* papillate; glochids usually all small and harmless; joints cylindroidal, usually uniformly spiny; plant shrubby, arborescent or treelike (3)
- 3(2). Terminal joints or at least some of them on each plant at least 15 mm. in diameter (4)
3. Terminal joints not more than 12 mm. in diameter (5)
- 4(3). Longer spines 3.8-5 cm. long; sheaths loose, of much greater diameter than the spines, 3-4 cm. in diameter; petaloid perianth parts yellow or yellowish-green 1. *O. tunicata*.
4. Longer spines 1-3 cm. long; sheaths close-fitting on the spines; petaloid perianth parts reddish-purple 2. *O. imbricata*.
- 5(3). Larger terminal branches 3-4.5 mm. in diameter; fruit bright-red, not tuberculate 3. *O. leptocaulis*.
5. Larger terminal branches 6-12 mm. in diameter; fruit reddish or mostly so, strongly tuberculate 4. *O. Kleiniae*.
- 6(1). Fruit green or reddish, becoming tan and dry as the seeds reach maturity, with at least an apical rim of divaricately-spreading strongly barbed spines; seeds usually 3-7.5 mm. in diameter, rough and irregular (7)
6. Fruit fleshy and juicy at maturity of the seeds, usually red or reddish-purple, nearly always spineless, with glochids (9)
- 7(6). Larger joints 50-125 mm. long, 38-100 mm. broad, broadly obovate to orbiculate, to 12 mm. thick, less than one quarter as thick as broad; spines (except on the fruits) not strongly barbed, the joints not detached readily 6. *O. polyacantha*.
7. Larger joints 25-38 mm. long, 25 mm. broad or less, flattened-obovoid or -ovoid, 12-19 mm. thick, at least one half as thick as broad; spines strongly barbed, the joints readily detached and clinging by the barbed spines (8)
- 8(7). Roots not bearing glochids; stigmas 10, oblong, not apiculate; fruit obovoid, 12-15 mm. long, 10 mm. in diameter 7. *O. fragilis*.
8. Roots bearing areoles and masses of glochids, 3-12 dm. long; stigmas 5, ovate-acute, apiculate; fruit vasselike, constricted above, 25-30 mm. long, 10 mm. in diameter .. 8. *O. arenaria*.
- 9(6). Spines present (10)
9. Spines none (18)
- 10(9). Plant 30-70 dm. high, usually a tree, the trunk commonly 10 dm. high or more; joints 2.25 or 3-6 dm. long; spines nearly white; fruit usually yellowish or tannish-orange; escape from cultivation 18. *O. Ficus-indica*.
10. Plant to only 24 dm. high (usually much less), rarely with a main trunk to 3 dm. long; joints rarely to 2-3 dm. long; fruit red to purple at maturity; native species (11)

- 11(10). Spines acicular (needlelike), elliptic to nearly circular in cross section (sometimes an occasional spine flattened basally), 1 to 3 per areole, not all the spines yellow (12)
11. Spines (at least some of the larger but not necessarily the smaller) subulate, *flattened at least at the bases*, usually 3 or more per areole (15)
- 12(11). Plants low and mat-forming, usually prostrate; largest joints usually 5-7.5 or 11 cm. long, 38-75 cm. broad; spines white, gray or brownish (13)
12. Plants arising the height of several joints, 3-21 dm. high; joints 10-17.5 cm. or 30 cm. long, usually 7.5-15 or 20 cm. broad; spines tan, brown, pink, gray, black, reddish-brown or sometimes white (14)
- 13(12). Seed margin (covering the embryo) smooth and regular, 0.5 mm. broad; joints green; petaloid perianth parts yellow; spines gray or brownish, few on the joint, 1 or rarely 2 per areole, 19-30 mm. long, 0.5-0.7 mm. in diameter, spreading; roots fibrous10. *O. compressa*.
13. Seed margin irregular, 1 mm. broad or more; joints glaucous; petaloid perianth parts yellow, usually with red bases; spines usually white or pale-gray, 1 to 6 per areole, 38-56 mm. long, 0.5 mm. in diameter, mostly deflexed; main root usually tuberous11. *O. macrorrhiza*.
- 14(12). Spines in each of the upper areoles of the joint 3 to 7 or 11; joints green during favorable seasons, sometimes partly lavender to reddish-purple in cold or dry weather; petaloid perianth parts pale-yellow12. *O. atrispina*.
14. Spines in each of the upper areoles of the joint 1 or sometimes 2 or rarely 3 in some areoles; joints strongly tinted with lavender or reddish-purple at all seasons; petaloid perianth parts yellow with red bases and centers13. *O. violacea*.
- 15(11). Spines *all* (1 to 6 or 8 per areole) *deflexed* (except the longest one in each of a few areoles at the top of the joint), one lower spine markedly longer than the others, reddish-brown basally, shading to yellow apically (changing to black in age); fruit red, spheroidal, 1.2-2 cm. in diameter ... 17. *O. Strigil*.
15. Spines not all deflexed, spreading in various directions, no single lower spine in the areole markedly longer than the others (16)
- 16(15). Spines *not all* yellow, at least some of them gray, tan, brown, reddish or white or strongly so basally; joints glaucous14. *O. phaeacantha*.
16. Spines *all* yellow (or slightly colored basally), turning drab-gray or black in age and often so in pressed specimens (17)
- 17(16). Fruit obovoid to elongate-obovoid, sometimes sterile basally in parasitized fruits; seeds 3-4 mm. in diameter; inner sepeloid perianth parts truncate or emarginate15. *O. Lindheimeri*.
17. Fruit elongate-obovoid, the base normally constricted and forming a sterile short stalk; seeds 4-6 mm. in diameter; inner sepeloid perianth parts acute or acuminate16. *O. stricta*.
- 18(9). Plant a tree, 3-6 m. high, the trunk commonly 1 m. high; cultivated, sometimes escaped18. *O. Ficus-indica*.
18. Plant not treelike, *not* with a main trunk; fruits 1.9-5 cm. long (19)
- 19(18). Joints pubescent, gray-green; glochids deciduous, reddish-brown, flying into the air when the plant is disturbed; flowers yellow; fruit bright-red 9. *O. rufida*.
19. Joints glabrous; glochids persistent (20)
- 20(19). Joints green (lavender- or purple-tinged in winter), *not glaucous* (21)
20. Joints glaucous (sometimes lavender- or purple-tinged at least in winter) (22)
- 21(20). Joints orbiculate to obovate, 5-11 cm. long, 4-11 cm. broad 10. *O. compressa*.
21. Joints narrowly obovate to narrowly elliptic or oblong, 10-20 or 35 cm. long, usually 7.5-10 or up to 20 cm. broad16. *O. stricta*.

- 22(20). Joints with a betacyanin pigment (lavender or purple) conspicuous at all seasons (intensified during cold weather or drought)
 13. *O. violacea*.
22. Joints green or (in some hybrids) glaucous (except during extreme cold or drought)
 18. *O. Ficus-indica*
 (hybrids).

1. *Opuntia tunicata* (Lehm.) Link & Otto. ABRJOJO. Bushy or mat-forming cholla 3-6 dm. high; joints 1-2.5 dm. long, 1.5-2 cm. in diameter; tubercles strongly raised, 1.2-3 cm. long, 3-9 mm. high; spines reddish-brown (the conspicuous sheaths lighter colored and papery), 6 to 10 per areole, 3.8-5 cm. long, basally 1-1.5 mm. (sheaths 1.5-4 mm.) broad; flower 3 cm. in diameter; petaloid perianth parts greenish-yellow or tinged with red; fruit fleshy, tuberculate, 3 cm. long, the umbilicus cuplike.

Var. *tunicata*. SHEATHED CHOLLA. Joints not strongly woody, readily detached, 5-25 cm. long, 2.5-3 cm. broad; tubercles 2-3 cm. long; spines 4.4-5 cm. long; sheaths whitish-tan, 2-4 mm. in diameter, remarkably loose. Desert hillsides and fans at 1,500 m., Pecos and Brewster cos.; s. to Mex. and Chile.

Var. *Davisii* (Engelm.) L. Benson. Joints strongly woody, *not* readily detached, 5-15 cm. long, about 1 cm. in diameter; tubercles 12-15 mm. long; spines about 38 mm. long; sheaths golden-tan, 1.5-2 mm. in diameter, loose. Sandy soils at 600-1,500 m. in w. Tex., w. Okla. and e. N.M.

2. *Opuntia imbricata* (Haw.) DC. TREE CHOLLA, COYONOSTLE. Usually a small tree 1-2 m. high; joints cylindroidal, 1.25-3.75 dm. long, 2-3 cm. in diameter; tubercles prominent, very sharply raised, 2-3.5 cm. long; spines usually red or pink (the sheaths dull-tan), 10 to 30 per areole, 12-28 mm. long, basally 0.5 mm. broad, strongly barbed; flower 5-7.5 cm. in diameter; petaloid perianth parts reddish-purple; fruit yellow, fleshy, strongly tuberculate, obovoid, 25-44 mm. long. *O. arborescens* Engelm.

Var. *imbricata*. Arborescent or usually a tree 1-2 or 3 m. high; joints not glaucous, 12.5-37.5 cm. long, 2-3 cm. in diameter; tubercles 2.5-5 cm. long; spines 10 to 30 per areole, these and the sheaths red, pink or brown. Gravelly or sandy soils at 1,200-1,800 m. in Trans-Pecos Tex.; from Colo. to Ariz., N.M., Kan., Okla. to w. Tex., s. to cen. Mex.

Var. *argentea* Anthony. Small shrub to 12 dm. high, often forming thickets; joints glaucous, 1-2 dm. long, 16-38 mm. in diameter, relatively stouter than in var. *imbricata*, the tubercles smaller, being 2 cm. long; spines 10 to 20 per areole, these and the sheaths silvery. Deep soils of desert bottomlands at 600-720 m., Brewster Co.; endemic.

3. *Opuntia leptocaulis* DC. DESERT CHRISTMAS CACTUS, TASAJILLO, TESAJO. Small shrub; joints of the main branches to 3-4 dm. long; larger terminal joints much shorter, cylindroidal, 25-75 mm. long, 3-4.5 mm. in diameter; tubercles almost lacking; spines (sometimes none) gray (the sheaths tan, conspicuous, loose-fitting), 1 per areole, 2.5-5 cm. long, basally 0.5 mm. in diameter, not markedly barbed; flower 1-1.5 cm. in diameter; petaloid perianth parts green to yellow or bronze; fruit bright-red, fleshy, juicy, obovoid, 12 mm. long, persistent. Heavier and bottomland soils at 60-900 or 1,500 m., from Ariz. to N.M., Okla. and w. and s. Tex.; also n. Mex.

4. *Opuntia Kleiniae* DC. KLEIN CHOLLA, TASAJILLO. Bush or shrub 3-20 dm. high; joints cylindroidal, partly purplish-red, 1-3 cm. long, 6-9 mm. in diameter; tubercles prominent, 12-15 or 25 mm. long; spines grayish-pink (the sheaths tan, loose), 1 to 4 per areole, 19-25 or 30 mm. long, basally to 0.5 mm. in diameter, markedly barbed; flower 3-5 cm. in diameter; petaloid perianth parts reddish to purple; fruit red to green and red, fleshy but only slightly juicy, tuberculate, obovoid, 2 cm. long. Rocky soils of desert hillsides from s. N.M. to Tex. w. of the Pecos River.

5. *Opuntia Schottii* Engelm. CLAVELLINA. Mat-forming cholla, the clumps to 7.5-10 cm. high and 1-3 m. in diameter; joints clavate, 38-62 mm. long, 12 or 15-25 mm. in diameter; tubercles mammillate, 4.5-15 mm. long; spines in the uppermost areoles of the joint, brownish or gray tinged with pink or red, sheathed only at the tips, papillate-roughened, 6 to 12 or 15 per areole, 2.5-5 cm. long, 1-1.5 mm. broad; flower 5 cm. in diameter; petaloid perianth parts yellow; fruit yellow, fleshy, expanded upward, 38-56 mm. long, 12-38 mm. in diameter. (?) *O. Stanlyi* of Tex. ref.

Var. *Schottii*. Larger spines flattened, basally 1-1.5 mm. broad, brownish or yellowish, becoming gray, 6 to 10 or 12 per areole, faintly ridged and grooved lengthwise, clearly papillate-roughened. Sandy soils of valleys at 300-1,200 m. in w. Tex. and n. Mex.

Var. *Grahamii* (Engelm.) L. Benson. Larger spines only slightly flattened, basally 1 mm. broad, tan or gray tinged with pink or red, 8 to 12 or 15 per areole, not ridged or grooved, minutely papillate-roughened. Sand of desert dunes and flats at 700-1,500 m. in N.M. and Tex. w. of the Pecos River.

6. *Opuntia polyacantha* Haw. PLAINS PRICKLY PEAR. Clumps 7.5-15 cm. high and 3 dm. to several m. in diameter; joints bluish-green, orbiculate to broadly obovate, 5-10 cm. long, 2.5 or 5-10 cm. broad, not readily detached; spines white to reddish-brown or gray, 6 to 10 per areole, mostly deflexed, 2.5-8 cm. long, basally 0.25-0.5 mm. in diameter, acicular, not strongly barbed; flower 4.4-8 cm. in diameter; petaloid perianth parts usually yellow; fruit tan or brown, dry, obovoid, 2-3.8 cm. long.

Var. *polyacantha*. Spines in the lower areoles rigid, straight, 6-12 mm. long, in the upper 25-38 or 56 mm. long, basally 0.5 mm. in diameter; fruit densely spiny. Sandy soils, Alta. and Sask. to Ida., Colo., w. Okla. and Tex. (Panhandle).

Var. *rufispina* (Engelm.) L. Benson. Spines in the lower areoles rigid, straight, 1.2-3 cm. long, in the upper 4.4-8 cm. long, sometimes reddish-brown, basally 0.5-0.75 mm. in diameter; fruit densely spiny. Calif. to Colo., N.M. and Trans-Pecos Tex.

Var. *trichophora* (Engelm. & Bigel.) Coult. Spines in the lower areoles (especially on basal joints) threadlike, flexible, curving or undulating, white or pale-gray, 38-75 mm. long, in the upper 25 or 38 mm. long, reddish-brown or pale-gray, basally 0.75 mm. in diameter; fruit with few to many weak spines. Panhandle and Trans-Pecos; Colo. to Ariz., w. Okla. and Tex.

7. *Opuntia fragilis* Nutt. LITTLE PRICKLY PEAR. Mat-forming; joints glaucous, flattened-obovoid or -ovoid or elliptic, 2-4.4 cm. long, 12-25 or 38 mm. broad, 1.2-2 cm. thick, at least one half as thick as broad, readily detached and clinging by the barbed spines; spines white or pale-gray, 1 to 6 or 9 per areole, 12-25 mm. long, basally 0.7 mm. in diameter, acicular; flower 3.8-5 cm. in diameter; petaloid perianth parts green edged with yellow; fruit greenish, becoming dry and tan, obovoid, 12-15 mm. long. B. C. to s. Mich., Calif. and Tex. (Panhandle).

8. *Opuntia arenaria* Engelm. Patches 3-9 dm. in diameter; roots (?) or rhizomes 3-12 dm. long, bearing areoles and glochids; joints glaucous, narrowly obovate-oblong, 5-7.5 or 10.6 cm. long, 2-2.5 cm. broad; spines white to gray or reddish-tan, 5 to 7 per areole, the longer ones 25-34 mm. long, basally 0.5 mm. in diameter; flower 38-62 mm. in diameter; petaloid perianth parts yellow; fruit green, changing toward tan, dry, with white spines, vasselike, constricted below the apex, 2.5-3 cm. long, 1 cm. in diameter. Sandy areas near the Rio Grande at 1,120-1,350 m., El Paso Co.; in N.M. and Tex.; also Chih.

9. *Opuntia rufida* Engelm. BLIND PRICKLY PEAR. Shrub 1-1.5 m. high; joints blue-green to gray-green, orbiculate, 7.5-15 or 25 cm. in diameter; spines none; glochids reddish-brown, conspicuous, readily detached; flower 62-75 mm. in diameter; petaloid perianth parts pale-yellow, changing to orange; fruit bright-red, fleshy, 25 mm. long. Rocky desert hillsides at 600-1,050 m. in Tex. in the Big Bend; also Chih. and Coah.

The vernacular name is from the blinding of cattle by glochids.

10. *Opuntia compressa* (Salisb.) Macbr. EASTERN PRICKLY PEAR. Clump- or mat-forming prickly pears 7.5-10 cm. high; roots *not* tuberous; joints green to lead-color or in winter reddish-purple, orbiculate to obovate or elliptic, 5-7.5 or 10 cm. long, 38-62 or 100 mm. broad; spines from the upper areoles of the joint, gray or brownish, 1 per areole, spreading at right angles, 25-38 mm. long, basally 0.5-1 mm. in diameter, acicular; flower 38-62 mm. in diameter; petaloid perianth parts yellow; fruit purple or reddish, obovoid, fleshy, 25-38 mm. long. Sand and rock at mostly 600 m., Mont. (rare) to s. Ont., Mass., Okla., e. Tex. and Fla.

11. *Opuntia macrorhiza* Engelm. PLAINS PRICKLY PEAR. Clump-forming prickly pear, 7.5-12.5 cm. high; main root(s) usually tuberous, the others fibrous; joints glaucous, orbiculate to obovate, 5-10 cm. long, 5-6.2 cm. broad; spines mostly from the uppermost areoles, usually white or gray, 1 to 6 per areole, mostly deflexed, 38-56 mm. long, slender, basally 0.25 or 0.5 mm. in diameter, acicular; flower 5-6.2 cm. in diameter; petaloid

perianth parts yellow or tinged basally with red; fruit reddish-purple, fleshy, obovoid, 25-38 mm. long.

Var. *macrorhiza*. Moderately glaucous; joints 62-75 or 100 mm. long; spines 0.5 mm. in diameter; flowers yellow or the centers reddish. Sandy or rocky soils of plains at 600-2,100 m., Calif. to S.D., s. Mich., w. Mo., w. Ark., w. and s. Tex. and La.

Var. *Pottsii* (Salm-Dyck) L. Benson. Strongly glaucous; joints 5-6.2 cm. long; spines very slender, about 0.25 mm. in diameter; flowers reddish. Sand or loam on plains at mostly 1,200-1,800 m., from Ariz. to N.M. and Tex. in the Panhandle and w. of the Pecos River.

12. *Opuntia atrispina* Griffiths. Sprawling or suberect prickly pears, 4.5-6 dm. high; roots not tuberous; joints green, obovate to nearly orbiculate, 10 or up to 15 cm. long, 7.5 or up to 10 cm. broad; spines on the upper portion of the joint, mostly black but apically shading to yellow, mostly 4 to 7 per areole, the principal one ascending, 25-38 mm. long, basally to 1 mm. in diameter, acicular; flower 5-6.2 cm. in diameter; petaloid perianth parts few, pale-yellow; fruit reddish-purple, fleshy, globose to pyriform, 1.2-2 cm. long. Limestone at 450-700 m. in Tex. from Presidio Co. to Nolan and Uvalde cos.

13. *Opuntia violacea* Engelm. PURPLE PRICKLY PEAR. Shrub or treelike; joints at all seasons tinged by betacyanin pigments (reddish-purple), tending to be orbiculate; flower 75-87 mm. in diameter; petaloid perianth parts few, yellow with bright-red bases and lower middles; fruit red or purplish-red, fleshy, obovoid, 25-38 mm. long. N.A.

Var. *santa-rita* (Griffiths & Hare) L. Benson. Joints orbicular, 15-20 cm. long; spines none or few, often 2 to 4 on the upper margin of the joint, 1 per areole, light reddish-brown, 38-62 mm. long, 0.25-0.3 mm. in diameter. Ariz., N.M. and Tex. w. of the Pecos River.

Var. *macrocentra* (Engelm.) L. Benson. Joints mostly broadly obovate, 15-17.5 cm. long; spines abundant on and just below the upper margin of the joint, 1 or 2 per areole, nearly black, 5 or 7.5-17.5 cm. long, 1 mm. in diameter. In s. N.M. and Tex. w. of the Pecos River; also Chih.

Var. *Castetteri* L. Benson. Joints mostly broadly obovate, 15-17.5 cm. long; spines abundant on and just below the upper margin of the joint, 2 or 3 per areole, white or mostly so, 6.2-12.5 cm. long, 1 mm. in diameter. In s. N.M. and Tex. w. of the Pecos River.

14. *Opuntia phaeacantha* Engelm. Prostrate to suberect prickly pears, in clumps 6-24 or 60 dm. in diameter and 3-6 or 9 dm. high, or sometimes with chains of several joints on edge along the ground; joints bluish-green, in cold weather with some lavender to purple betacyanin pigmentation, obovate to orbiculate, 1-1.5 or 2.5 or rarely 4 dm. long, 7.5-22.5 cm. broad; spines (or some of them) clearly flattened; flower 6.2-8 cm. in diameter; petaloid perianth parts yellow or the bases red; fruit purplish, fleshy, usually obovate, 31-62 mm. long.

Var. *phaeacantha*. Joints obovate, 1-1.5 dm. long, 7.5-10 cm. broad; spines over the upper three fourths of the joint, brown, 38 or 44-62 mm. long, 0.7-1 mm. broad, 3 to 5 or 9 per areole. Ut. to Colo., Ariz., N. M. and Tex. (Big Bend).

Var. *camanchica* (Engelm. & Bigel.) L. Benson. Joints broadly obovate to orbiculate, 14-17.5 cm. long, 11-14 cm. broad; spines over almost the entire joint, dark-brown, 4 or 5-5.7 cm. long, 1-1.5 mm. broad, 5 to 8 per areole. N.M., w. Okla. and Tex. (Panhandle).

Var. *spinosibacca* (Anthony) L. Benson. Joints orbiculate, 14.15 cm. long and the same breadth; spines over almost the entire joint, brownish-red, 75 mm. long, 1 mm. broad, 2 to 6 per areole; fruit spiny at the top (in only this variety). Big Bend area.

Var. *major* Engelm. Joints broadly obovate or sometimes orbiculate, 12.5-25 cm. long, 1-2 dm. broad; spines over the upper one half, one third or less of the joint, dark-brown, 30 or 56-69 mm. long, usually 1-1.5 mm. broad, usually 1 to 3 per areole. Calif. to Ut., Kan. and cen. Tex.

Var. *discata* (Engelm.) L. Benson & Walkington. Joints orbiculate to elliptic, 2.25-3 or 4 dm. long, 1.75-2.25 dm. broad; spines on the entire joint, white or ashy-gray, 2.5-5 cm. long, usually 1 or 1.5 mm. broad, 1 to 4 or rarely 10 per areole. *O. Engelmannii* of auth., not Salm-Dyck. Calif. to Ut. and Tex. (e. hills of Edwards Plateau); also Son. and Chih.

15. *Opuntia Lindheimeri* Engelm. TEXAS PRICKLY PEAR, NOPAL PRICKLY PEAR, CACANAPO. Shrubs 1-3 m. high; joints green or (westward) sometimes blue-green,

obovate to orbiculate or rarely elongate, usually 15-25 or 30 cm. long, usually 1.25-2 or 2.5 dm. broad; spines usually in all but the lower areoles, yellow or sometimes whitish-yellow (or the very base black, brown or red), 1 to 6 per areole, usually one spreading, 12-38 or 50 mm. long, basally 0.7 mm. broad, subulate; flower 5-7.5 or 10.6 cm. in diameter; petaloid perianth parts yellow; fruit purple, fleshy, obovate or elongate, 3.1-7 cm. long.

Var. *Lindheimeri*. Joints determinate, obovate to sometimes orbicular, flat, 15-25 or 30 cm. long, 12.5-20 or 25 cm. broad; spines 1 to 6 per areole, in nearly all the areoles, 12-38 or 50 mm. long. Rare in s. N.M., Tex. and Mex.

Var. *tricolor* (Griffiths) L. Benson. Joints determinate, obovate, flat, 17.5-20 or 25 cm. long, 15-17.5 or 20 cm. broad; spines 1 to 3 or 6 per areole, in nearly all the areoles, 5-7.5 cm. long. In s. Tex.

Var. *Lehmannii* L. Benson. Joints determinate, broader than long, wavy, 22.5-25 cm. long, 22.5 or 25-30 cm. broad; spines 3 or 4 per areole, in all but the lower areoles, 1.9-3 cm. long. Kleberg Co. and s.

Var. *linguiformis* (Griffiths) L. Benson. COW-TONGUE PRICKLY PEAR. Joints apically meristematic, elongate, lanceolate to linear-lanceolate, flat, 4.5-9 or 12 dm. long, 10-12.5 or 17.5 cm. broad; spines 1 to 3 per areole, distributed irregularly or on some joints lacking, 12-19 mm. long. Tex. near San Antonio; widely cult. and sporadically introduced in Tex. and elsewhere.

16. *Opuntia stricta* Haw. Shrub 6-20 dm. high; joints green, narrowly obovate or narrowly elliptic to nearly oblong, 1.75-2.5 or 4 dm. long, 7.5-15 or 25 cm. broad; flower 5-6.2 cm. in diameter; petaloid perianth parts light-yellow; fruit purple, fleshy, obovoid, 38-65 mm. long.

Var. *stricta*. SOUTHERN SPINELESS CACTUS. Joints narrowly elliptic or narrowly obovate, 1.75-2.5 dm. long, 7.5-12.5 cm. broad; spines none or sometimes a few solitary ones in marginal areoles. Sandy soils just above sea level from e. Tex. to Va. and Fla.; also Cuba and Bah. I.

Var. *Dillenii* (Ker) L. Benson. Joints obovate, 1-3 or 4 dm. long, 1.25-1.75 or 2.5 dm. broad; spines 1 to 11 per areole, 12-37 or 62 mm. long. Sandy soils and shell mounds, coastal from Tex. to S.C. and Fla.; also Mex., S.A., W.I. and Berm.

17. *Opuntia Strigil* Engelm. Ascending or sprawling, 6-10 dm. high; joints slightly glaucous, obovate, 10-12.5 cm. long, 8.8-10 cm. broad; spines reddish-brown with yellow tips, 5 to 8 per areole, one much larger, all turned downward or the principal one from each upper marginal areole ascending, the longer ones 12-38 mm. long, basally 0.75 mm. broad, a little flattened; flower 5 cm. in diameter; fruit red, fleshy, spheroidal, 1.2-2 cm. in diameter. Limestone soils at 900-1,350 m. in Tex. from Pecos Co. to Nolan, Crockett and Webb cos.

18. *Opuntia Ficus-indica* (L.) Mill. INDIAN FIG, NOPAL DE CASTILLA. Tree 3-5 m. high; trunk 6-12 dm. long, 2-3 dm. in diameter; joints green, obovate or oblong, 3-6 dm. long, 2-4 dm. broad; spines none, few or abundant, white or on some joints tan or pale-brown, 1 to 6 per areole, 12-25 or 38 mm. long, basally 0.7-0.8 mm. broad, subulate; flower 7.5-10 cm. in diameter; petaloid perianth parts yellow or orange; fruit yellow, orange, red or purplish in various strains, fleshy, edible, 5-10 cm. long, 4-8.7 cm. in diameter. Mex.; common in cult. as *O. Ficus-indica* (spineless) and *O. megacantha* (spiny); often an escape and (as in Austral. and S. Afr.) a pest; occasional escape in Tex. and hybridizing occasionally with *O. phaeacantha* or *O. Lindheimeri*.

2. CEREUS MILL.

Stems branching slightly to freely, elongate, cylindroid to prismatic, 15 to 100 times as long as their diameter; ribs 3 to many; leaves none; spines 1 to many per areole, acicular; flower below the growing apex of the stem, within the edge of the spine-bearing part of the areole; flower 2.5-15 or 22.5 cm. in diameter; floral tube above the ovary almost obsolete to funnelform or tubular; fruit fleshy, indehiscent; seed longer than broad (hilum to opposite side); hilum obviously basal, sometimes oblique; cotyledons minute, incumbent.

Many species from California, Arizona, New Mexico, Texas and Florida to South America.

1. Stems or *most of them* at maturity triangular in cross section, sharply 3-angled, 25-50 mm. thick; roots *not* tuberous; larger spines 25-40 mm. long; flower about 1 dm. in diameter, white1. *C. pentagonus*.
1. Stems at maturity terete or 4- to 6-ribbed, slender, basally 4.5-6 mm. in diameter, enlarging upwards to 6-12 mm., roots forming one or more large tubers; spines slender and weak, to 9 mm. long (2)
- 2(1). Stems strongly 4- to 6-ribbed, the intervening troughs deep; style and stamens not projecting above the perianth parts; tuber one, weighing from 1.5 to 43 pounds; some spines not parallel to the stem surface; superior floral tube 100-150 mm. long; flowers white2. *C. Greggii*.
2. Stems 6- to 10-grooved, the ridges only 1-1.5 mm. high; style and stamens projecting beyond the perianth parts; tubers several; spines all lying parallel to the stem surface; superior floral tube 9-12 mm. long; flowers pink to purple3. *C. Poselgeri*.

1. *Cereus pentagonus* (L.) Haw. BARBED-WIRE CACTUS. Sprawling; stems several m. long, 2.5-5 cm. in diameter; ribs of mature branches 3 (rarely 4 or 5), strongly divergent and sharply angled; spines gray, 7 or 8 per areole, 1 or 2 central, mostly 2.5-4 cm. long; flower 1 dm. in diameter; petaloid perianth parts white; ovary with scale leaves to 12 mm. long; fruit red, shiny, sweet, with many spines each about 12 mm. long; seed 3 mm. long. Coastal thickets and jungles, Tex. along the Rio Grande from Laredo downstream; also Fla. s. to n. S.A.

2. *Cereus Greggii* Engelm. DESERT NIGHT-BLOOMING CEREUS. Inconspicuous plant; stems erect or sprawling, 3-6 or 24 dm. long, to 12 mm. in diameter, very slender below, strongly 4-, 5- or 6-ribbed above, canescent; root turniplike; spines 11 to 13 per areole, to 3 mm. long, mostly parallel to the surface; flower nocturnal, 5-7.5 cm. in diameter; floral tube 10-15 cm. long; petaloid perianth parts white; fruit red, the areoles bearing short spines; seed 3 mm. long. Flats and washes in the desert at 1,200-1,500 m., s. N.M. and Tex. w. of the Pecos River; also Chih. and Zac.

3. *Cereus Poselgeri* Lem. SACASIL. Suberect plant with a cluster of tuberous roots; stem 3-6 dm. high, 6-9 mm. in diameter, slender, cylindroidal; ribs 8 to 10, low; spines tan or brown, 1 central and 12 to 16 radials per areole, appressed; flower diurnal, opening more than one day, 38-44 mm. in diameter; petaloid perianth parts pink to purple; fruit with wool and minute spines; seed 1 mm. long. Semidesert brushlands at low elev. in s. Tex. near the Rio Grande; also Coah., N.L. and Tam.

3. ECHINOCEREUS ENGELM.

HEDGEHOG CACTUS

Stems solitary to profusely branching, up to 500, cylindroidal; ribs 5 to 12; leaves not discernible; central spines 1 mm. to 1 dm. long, acicular or subulate; radial spines 3 to 32; flower on the old growth below the apex of the stem, bursting through the epidermis just above the spine-bearing areole and forming an irregular scar; flower 2-12.5 cm. in diameter; fruit fleshy, with ultimately deciduous areoles bearing spines; seeds black, usually longer than broad (hilum to opposite side); embryo nearly straight; cotyledons minute, incumbent.

Twenty to thirty species from California to South Dakota and Oklahoma, south to Mexico.

1. Petaloid perianth parts red or red and yellow (with no trace of blue); areoles of the mature parts of stems bearing white felt or cobwebby hairs; flowers not closing at night, remaining open for 2 or 3 days1. *E. triglochidiatus*.
1. Petaloid perianth parts *either* (1) lavender to purple *or* (2) yellow, green, brownish or reddish (but then with an admixture of blue); areoles of the *mature vegetative parts of stems not* bearing white or cobwebby hairs, the felt of the young areoles persistent for 1 or rarely 2 years; flowers closing at night and reopening (2)

- 2(1). Flower 38-125 mm. in diameter (3)
 2. Flower 19-25 mm. in diameter (9)
- 3(2). Stem ribs 4 to 6 or rarely 8 (then with prominent tubercles); stems creeping, slender and elongate, 1.9-3 cm. in diameter; spines not obscuring the joints, gray to nearly black or brown (4)
3. Stem ribs 9 to 22 or uncommonly 7 or 8 (vars. of *E. enneacanthus*); stems (if at maturity less than 5 cm. in diameter) *either* (1) with the joints only 1 to 3 times as long as their diameter *or* (2) *not* decumbent *or* (3) *with* at least some straw-colored spines *or* (4) *with* the spines tending to obscure the joints (5)
- 4(3). Petaloid perianth parts narrowly oblong to linear-lanceolate, acute and mucronate, 6-8 mm. broad; stem joints mostly 7.5-15 cm. long, 20-30 mm. in diameter, 5- or 6-ribbed; central spine usually 2-2.5 cm. long, 0.5 mm. in diameter; radial spines shorter than the central, 0.25 mm. in diameter; papillae on the seed coat large 2. *E. Blanckii*.
4. Petaloid perianth parts broadly oblanceolate to cuneate, rounded or truncate, often erose, 8-12 mm. broad; stem joints 5-10 cm. long, 12-16 mm. in diameter, 4- or 5-ribbed; central spines (if any) 1-2 cm. long, absent from many to nearly all areoles, 0.75 mm. in diameter; radial spines about as long as most of the centrals, 0.5 mm. in diameter; papillae on the seed coat small 3. *E. pentalophus*.
- 5(3). Areoles practically circular (6)
5. Areoles vertically elongate, elliptic to linear, close-set, 6-8 mm. apart, the spines dense; stems usually unbranched or with few branches (8)
- 6(5). Central spines 2 to 5, all similar, acicular, the longest central spine shorter than the longest radial; areoles 6-9 mm. apart, the spines obscuring the stem; stems usually unbranched 6. *E. Lloydii*.
6. Central spine(s) dissimilar, the lower one in the areole dominant (7)
- 7(6). Principal central spine *not flattened*, solitary or accompanied by a short upper accessory central; central and radial spines strongly differentiated 4. *E. Fendleri*.
7. Principal central spine basally flattened (that is, narrowly elliptic in cross section), deflexed, the 4 central spines all well-developed; spines not strongly differentiated into types, the centrals similar to the radials 5. *E. enneacanthus*.
- 8(5). Spines of the floral tube (on the ovary and above it) stout and rigid, the associated hairs short; petaloid perianth parts apically rounded; stigmas about 3 mm. long, stout; fruit 20-62 mm. long; seed 1.2-1.3 mm. long; flower 62-125 mm. in diameter 7. *E. pectinatus*.
8. Spines of the floral tube slender and somewhat flexible, the associated hairs long and cobwebby; petaloid perianth parts acuminate; stigmas about 6 mm. long, broad; fruit 15 mm. in diameter 8. *E. Reichenbachii*.
- 9(2). Areoles elliptic or elongate, each with 1 or 2 series of spines; central spines 0 or 1 or sometimes 2 or 3 per areole, 0.5-0.7 mm. in diameter; petaloid perianth parts 3-4 mm. broad 9. *E. viridiflorus*.
9. Areoles circular, each with 3 series of spines (arbitrarily, the innermost central and the other 2 radial); central spines 5 or 6, 0.3-0.4 mm. in diameter; petaloid perianth parts 2-3 mm. broad 10. *E. chloranthus*.

1. *Echinocereus triglochidiatus* Engelm. CLARET-CUP. Plants mostly branching several to many times, forming mounds; joints 5-15 or 30 cm. long, 25-75 or 100 mm. in diameter; ribs 5 to 10 or 12; areoles nearly circular; spines usually gray but sometimes pinkish, straw-color, pale-gray or black, 2 or 3 or commonly 8 to 12 or 16 per areole, exceedingly variable in the varieties; flower 3-5 cm. in diameter; petaloid perianth parts red; fruit red, obovoid to cylindroid, 12-25 mm. long; seed strongly papillate, 1.5-2 mm. long.

Var. *melanacanthus* (Engelm.) L. Benson. Stems up to 500, 38-75 or 150 mm. long, 2.5-5 or 6.25 cm. in diameter; ribs mostly 9 or 10, tuberculate; central spines 1 to 3,

to 0.7 mm. in diameter; radial spines 5 to 11, half to sometimes nearly as long as the central; flower 3.1-5 cm. long; style 1 mm. in diameter. Ut. to s. Colo., Ariz., s.w. and cen. Tex.; also s. to Dgo.

Var. *neomexicanus* (Standl.) L. Benson. Stems 2-3 dm. long, 7.5-10 cm. in diameter; ribs 8 to 12, mostly 10, not markedly tuberculate; central spines 2 to 4, 0.5-1 mm. in diameter; radial spines 9 to 12, about half as long as the central; flower 5-6.9 cm. long; style 1 mm. in diameter. Ariz., N.M., Trans-Pecos Tex. and n.w. Mex.

Var. *Gurneyi* L. Benson. Stems few, 2-3 dm. long, 7.5-10 cm. in diameter; ribs 10 to 12, not markedly tuberculate; central spines 1 (or 2), 0.5 mm. in diameter; radial spines 7 to 9, about equal to the central; flower 5-6.9 cm. long; style 1.5 mm. in diameter. N.M. and Trans-Pecos Tex.

Var. *paucispinus* (Engelm.) L. Benson. Stems few, 15-20 cm. long, 6.2-10 cm. in diameter; ribs 5 to 7, not strongly tuberculate; central spines 0; radial spines 4 to 6; flower 25-38 mm. long; style 1.5 mm. in diameter. S.w. Tex. from Val Verde Co. to Kimble and Uvalde cos.

2. *Echinocereus Blanckii* (Poselger) Palmer. Stems procumbent, forming clumps; joints prismatic or cylindroid, mostly 5-15 or 17.5 cm. long, 19-25 or 31 mm. in diameter; ribs 5 or 6, prominent to indistinct, somewhat to strongly tuberculate; areoles circular; spines gray; central spine usually 1, 6 or 19-25 mm. long, 0.5 mm. in diameter; radial spines 6 to 8 per areole, very slender; flower 62-75 mm. in diameter; petaloid perianth parts oblanceolate; fruit reddish; seed coarsely papillate, 1 mm. long.

Var. *Blanckii*. Stems numerous; joints mostly 5-15 cm. long, 19-25 mm. in diameter; petaloid perianth parts apically rounded, weakly cuspidate, irregularly denticulate, rose-purple or lighter, 3.8-5 cm. long, 9-12 mm. broad; central spine 6-12 mm. long. *E. Berlandieri* (Engelm.) Small. Fine soils in thickets at low elev. in s. Tex. from Webb and Jim Wells cos. to Nueces and Cameron cos.; also n.e. Mex.

Var. *angusticeps* (Link) L. Benson. YELLOW ALICOCHÉ. Stems 1 to 10; joints 1-1.75 dm. long, to 31 mm. in diameter; petaloid perianth parts pale-yellow with red bases, 25 mm. long, 1 cm. broad, acuminate; central spine 6-12 mm. long. Sandy loam or red gravel or limestone at low elev. in s. Tex. from Bexar Co. to the lower Rio Grande.

3. *Echinocereus pentalophus* (DC.) Rümpler. ALICOCHÉ. Procumbent, forming clumps; joints prismatic, to 1 dm. long, 19-25 mm. in diameter; ribs 4 or 5; tubercles about 6 mm. high; areoles nearly circular; central spine (if any) only slightly longer than the radials; radial spines gray or brown to black, 4 to 6 per areole, 1-2 cm. long, 0.5 mm. broad; flower 7.5-10 cm. in diameter; petaloid perianth parts reddish-violet, broadly oblanceolate to cuneate, truncate. Fine soils at low elev. in s. Tex. from Webb Co. to Bexar Co. and Cameron Co.; also n.e. Mex.

4. *Echinocereus Fendleri* Engelm. Stem usually 1 but up to 5, ovoid-cylindroid or cylindroid, 75-62 or 250 mm. long, 38-62 mm. in diameter; ribs 8 or 9 or 10; areoles circular; central spine gray tipped with brown or black, solitary, 12 or 25-38 mm. long, 0.5-0.75 mm. in diameter, acicular; radial spines white or pale-gray, 5 to 7 or 9 per areole; flower 5-6.2 cm. in diameter; petaloid perianth parts magenta; fruit green, turning reddish; seed reticulate-punctate, 1.5 mm. long.

Var. *Fendleri*. Stems usually ovoid to ovoid-cylindroid, 7.5-15 or 25 cm. long; central spine very dark at first but changing to gray in age, curving upward through its entire length, 25-38 mm. long; radial spines 9-12 mm. long. Sandy or gravelly soils at mostly 1,800-2,400 m., Colo., Ut., Ariz., N.M. and Tex. in El Paso and perhaps in Hudspeth and Culberson cos.; also Chih.

Var. *rectispinus* (Peeb.) L. Benson. Stems cylindroid, 10-17.5 or 25 cm. long; central spine pale-gray but at least tipped with brown or black, straight and projecting at right angles to the stem, 12-38 mm. long; radial spines 9-12 mm. long. Sand or gravel at 1,170-1,650 or 2,060 m. in Ariz., s.w. N.M. and Tex. from El Paso Co. to Culberson Co.

5. *Echinocereus enneacanthus* Engelm. Stems to 120 or 350, forming clumps up to several dm. high and 6 or 20 dm. in diameter; stems cylindroidal, 1.5-3 dm. long, 3.8-7 or 10 cm. in diameter; ribs 7 to 13; areoles circular; central spines straw-color or gray at maturity, 1 to 4 per areole, solitary in young plants, straight, 25-94 mm. long, about 1 mm. broad, somewhat flattened; radial spines 7 to 10 or sometimes 12 to 15 per areole; flower 5 or 7.5-12.5 cm. in diameter; petaloid perianth parts magenta to purplish; fruit red; seeds strongly tuberculate to pitted, 1-1.4 mm. long.

The fruit of this species (especially var. *stramineus*) has a fragrant odor and a flavor and texture resembling the strawberry. It is eaten fresh or is used for making preserves.

Var. *enneacanthus*. PITAYA. Stems mostly clustered, decumbent, 3.8-5 cm. in diameter; ribs 7 or mostly 8 to 10; areoles 1-2 cm. apart; spines not obscuring the stem, gray to straw-color, 7 to 12 (mostly 8) per areole; central spine usually 1, 2-3.8 or 5 cm. long; flower 5-8.7 cm. in diameter. Tex. (best-defined from Val Verde to Kimble, Kerr and Cameron cos.); also Chih. and N.L.

Var. *brevispinus* (W. O. Moore) L. Benson. Stems clustered, decumbent, 38-44 mm. in diameter; ribs 7 or 8; areoles 1-2 cm. apart; spines not obscuring the stem, gray or straw-color, 10 to 13 per areole; central spine usually 1, 12-22 mm. long; flower 5-5.6 cm. in diameter. Tex. from Val Verde Co. to Real, Bexar, Jim Wells and Hidalgo cos.; also Coah. and Tam.

Var. *stramineus* (Engelm.) L. Benson. STRAWBERRY CACTUS, SPINE-MOUND. Stems mound-forming, up to 350 or more, mostly erect or suberect, 5-7.5 cm. in diameter; ribs mostly 10 to 12; areoles 1-2 cm. apart; spines obscuring the stem, forming a conspicuous straw-colored mass, 9 to 12 per areole; central spines 2 to 4, 5-8.7 cm. long; flower 10-12.5 cm. in diameter. N.M. and Tex. from El Paso Co. to Brewster and Pecos cos.; also n. Chih.

Var. *dubius* (Engelm.) L. Benson. Stems clustered, decumbent, 5-7 or 10 cm. in diameter, ribs 7 to 9 or 10; areoles 2-4.4 cm. apart; spines not obscuring the stem, gray to straw-color, 6 to 12, mostly few; central spine(s) 1 or sometimes more, 5-9.4 cm. long; flower 7.5-10 cm. in diameter; seed less tuberculate than in the other varieties. Tex. in Hudspeth, Presidio and Brewster cos.; probably also n. Chih.

6. *Echinocereus Lloydii* Britt. & Rose. Stem(s) 1 or several, cylindroidal, 1.5-2 dm. long, 7.5-10 cm. in diameter; ribs 12; areoles circular; central spines red with some gray surface coating, 2 to 5 per areole, shorter than the longest radial spine in the same areole, to 12 mm. long, 0.8 mm. in diameter, acicular; radial spines 8 or 9 per areole, spreading irregularly; flower 5 cm. in diameter; petaloid perianth parts lavender or magenta; fruit green tinged with pink, the spines white, 15 mm. long; seeds strongly papillate, broader than long, 1 mm. long. Sandy or gravelly soils at about 900 m., N.M. and Tex. in Pecos Co.

7. *Echinocereus pectinatus* (Scheidw.) Engelm. Stem(s) solitary or 2 or 3, cylindroid, 1-3 dm. long, 6.2-10 cm. in diameter; ribs 15 to 22; areoles elliptic to narrowly elliptic; spines obscuring the stem, pink to pale-gray or straw-color or brown to white; central spines 0 to 9 per areole, in 1 to 3 vertical series, 1-7.5 mm. long, 0.35-0.5 mm. in diameter; radial spines 12 to 22 per areole, strongly pectinate to spreading rather irregularly, the longer ones 6-15 mm. long, 0.25-0.5 mm. in diameter, acicular; flower 62-125 mm. in diameter; petaloid perianth parts magenta to light-purple or lavender or yellow; fruit green or greenish-purple; seed papillate, 1.2-1.3 mm. long.

Var. *pectinatus*. Central spines 3 to 5 in 1 or sometimes 2 vertical series, 1-3 mm. long; radial spines 12 to 16, pink or pink-and-gray, 6-7.5 mm. long; flowers magenta, 62-87 mm. in diameter. Ariz. and Tex. near the Rio Grande from El Paso to Maverick Co.; also Mex.

Var. *Wenigeri* L. Benson. Central spines 1 to 3, ashy-white, in 1 vertical series, 2-3 mm. long; radial spines 14 to 16, ashy-white, 6 mm. long; flowers magenta, 5-7.5 cm. in diameter. Tex. from Sutton Co. to Terrell and Val Verde cos.; also Coah.

Var. *minor* (Engelm.) L. Benson. Central spines 2 to 5, about equal, in 2 series or irregular, 8-12 mm. long; radial spines 7 to 15, pink or pink-and-gray, 4.5-9 mm. long; flowers magenta, 62-75 mm. in diameter. Near El Paso and in the Big Bend; also N.M. and Chih.

Var. *neomexicanus* (Coul.) L. Benson. Central spines 3 or 7 to 9, in 2 or 3 vertical series, 3-7.5 mm. long; radial spines 18 to 22, pale-brown or pink, 9-12 mm. long; flowers yellow, 75-125 mm. in diameter. *E. dasyacanthus* Engelm. From El Paso Co. to Culberson and Brewster cos.; Chih., Tex., N.M. and Ariz.

8. *Echinocereus Reichenbachii* (Terscheck) Haage f. Stems solitary or branching, cylindroidal, 7.5-15 or 40 cm. long, 2.5-5 cm. in diameter; ribs about 12 to 18; areoles narrowly elliptic to linear; spines obscuring the stem; central spines none or 1 to 3 per areole, much smaller than the radials, 1-3 mm. long; radial spines basally straw-color, pale-gray or pink and distally pink to red, 12 to 32 per areole, 4.5-12 or 14 mm. long, 0.35 mm. in diameter, acicular; flower 5-7.5 cm. in diameter; petaloid perianth parts

pink to light-purple; fruit green, with soft conspicuous long deciduous wool from the areoles; seeds strongly tuberculate, 1.5 mm. long.

Var. *Reichenbachii*. Areole 3 mm. long, very narrow; central spines 0; radial spines 22 to 32, basally straw-color to pale-gray, distally pink, strikingly pectinate, each curving in a low arc, 4.5-6 mm. long. *Echinocereus caespitosus* Engelm. and var. *minor* Engelm. Okla. and n. and cen. Tex.

Var. *perbellus* (Britt. & Rose) L. Benson. Areole 2 mm. long, elliptic; central spines 0 or 1 and minute, 1 mm. long; radial spines 12 to 16 or 20, straw-color to pink, spreading somewhat irregularly at low angles, straight, 4.5-6 mm. long. Colo., Okla., N.M. and n.w. Tex.

Var. *Albertii* L. Benson. Areole 1.5 mm. long, elliptic; central spines 0 or 1, 2-3 mm. long, purple, very dark; radial spines 14 to 16, white with very dark-purple tips, closely pectinate, straight, 3-4 or 6 mm. long. Tex. in Jim Wells Co.

Var. *Fitchii* (Britt. & Rose) L. Benson. Areole 2 mm. long, elliptic; central spines 4 to 7, 2-6 mm. long; radial spines 18 to 22, white or straw-color, distally tan or brownish, spreading rather irregularly, slightly curving downward, 6-7.5 mm. long. From Webb Co. to Jim Hogg and Starr cos.

Var. *chisosensis* (W. T. Marsh.) L. Benson. Areole 2 mm. long, elliptic; central spines 1 to 4, not in a row, 6-12 mm. long; radial spines 12 to 14, the lower elongate, the upper rudimentary, white or ashy, spreading rather irregularly, straight, 6-12 mm. long. Near the Chisos Mts., Brewster Co.

Var. *albispinus* (Lahman) L. Benson. Areole 2 mm. long, narrowly elliptic; central spines 1 to 3, to 3 mm. long; radial spines 12 to 14, commonly dark and basally pink but distally red (or white, yellow or brown), spreading at various low angles, straight, to 12 or 25 mm. long. Okla. and Tex. panhandles.

9. *Echinocereus viridiflorus* Engelm. GREEN PITAYA. Stems usually solitary, ovoid to cylindroid or barrel-shaped, 2.5-20 or 25 cm. long, 25-75 or 100 mm. in diameter; ribs mostly 10 to 14, but sometimes 6 to 9; areoles 2-3 mm. long, elliptic; spines obscuring the stem; central spines red, reddish-brown, white, pale-gray or greenish-yellow, 1 or none or sometimes 2 or 3 or 4 per areole, the longer ones 1.2-2 or 2.8 cm. long, 0.5-0.7 mm. in diameter, acicular or subulate; radial spines 8 to 11 per areole, 0.2 mm. in diameter, flower 2-2.5 cm. in diameter; petaloid perianth parts green to magenta or reddish; fruit green; seeds tuberculate on the reticulate pattern, 1-1.5 mm. long.

Var. *viridiflorus*. Stems small, ovoid or elongate-ovoid, 2.5-5 or 7.5 cm. long, 25-38 mm. in diameter; ribs 10 to 14; spines red, reddish-brown, white or pale-gray; radial spines 3-4.5 mm. long, slender, 0.4 mm. in diameter, acicular, similar in all the mature areoles, the lateral ones in the areole larger; petaloid perianth parts green; anthers 0.7 mm. long, ovoid; fruit 6-9 mm. long. Wyo., S.D., N.M., Okla. and Tex. panhandles.

Var. *Davisii* (Houghton) L. Benson. Stem dwarf, turbinate or turbinate-ovoid, 1.2-2 or 2.5 cm. long, 9-12 or 19 mm. in diameter; ribs 6 to 9; spines gray tipped with red or only gray or white; radial spines about 7 on each side of the areole, pectinate, acicular, the upper ones rudimentary, in the top areoles of older plants the lower spines few, very stout and to 15 mm. long and 0.5 mm. in diameter; petaloid perianth parts yellow-green; anthers 0.7 mm. long, ovoid; fruit 6 mm. long. Tex. in n. Brewster Co.

Var. *Correllii* L. Benson. Stem medium, elongate-ovoid or cylindroid, 75-125 mm. long, 38-50 mm. in diameter; ribs 10 to 14; spines in horizontal bands of greenish-yellow and ashy-white; radial spines to 1 cm. long, slender, 0.4 mm. broad, subulate, similar in all the mature areoles, the lateral ones in the areole larger; petaloid perianth parts yellow-green; anthers 1 mm. long, narrow, lanceolate; fruit unknown. Tex. in Pecos and n. Brewster cos.

Var. *cylindricus* (Engelm.) Engelm. Stems large, cylindroid or some barrel-shaped, 10-20 or 25 cm. long, 5-7.5 cm. in diameter; ribs 10 to 14; spines red, reddish-brown, white or pale-gray; radial spines about 1 cm. long, stout, 0.5-0.75 mm. in diameter, acicular, similar in all the mature areoles, the upper ones in the areole smaller; petaloid perianth parts magenta to nearly red; anthers 1.3 mm. long, narrow; fruit 12 mm. long. N.M. and Tex. w. of the Pecos River.

10. *Echinocereus chloranthus* Engelm. Stems solitary or few, cylindroidal, 7.5-17.5 cm. long, 62-75 mm. in diameter; ribs mostly 14 to 17; areoles nearly circular; spines obscuring the stem; central spines red or red-and-white or brown, 5 or 6 per areole,

shorter than the radials, the longer ones 6-7.5 or 10 mm. long, spreading, slender, acicular; radial spines in two series, 15-20 per areole, to 12 mm. long; flower 25 mm. in diameter; petaloid perianth parts green to brownish-red or red-brown; seed tuberculate and reticulate, 1-1.2 mm. long. Limestone at 900-1,350 m., Tex. w. of the Pecos River; N.M.

4. MAMMILLARIA HAW.

FISH-HOOK OR PIN-CUSHION CACTUS

Stems simple or branching, ovoid to cylindroid, globose or turbinate, 2.5-10 or 30 cm. long, 2.5-7.5 or 15 cm. in diameter; tubercles separate; leaves not discernible; areoles usually circular; spines smooth; central spines 0 to several or sometimes not differentiated, straight, curved or hooked, acicular; radial spines usually smaller and of lighter color, 10 to 80 per areole; flowers on the old growth of preceding seasons below the apex of the stem, between the tubercles and not obviously connected with them or with the areoles upon them, 6-25 or 50 mm. in diameter; floral tube above the ovary funnellform or obconic, green tinged with the perianth color; fruit fleshy, without surface appendages; seed black to brown, rugose-reticulate or reticulate-pitted or smooth and shiny and faintly reticulate-pitted or tuberculate, longer than broad (hilum to opposite side), 1-2 mm. long; hilum obviously basal or oblique; cotyledons accumbent, *not* foliaceous.

Perhaps 100 species from California to Nevada, Utah, New Mexico, Oklahoma and Texas; Mexico and Venezuela.

1. Flower about 50 mm. in diameter; superior floral tube elongate; petaloid perianth parts yellow, stalked; tubercles soft, 12-19 or 50 mm. long 1. *M. longimamma*.
1. Flower less than 25 mm. in diameter or (if larger) pink to purple; superior floral tube cuplike; petaloid perianth parts pink, purple, yellow, salmon or white, not stalked; tubercles usually firm, less than 12 mm. long (2)
- 2(1). Juice of the tubercles milky; stem broadly turbinate or depressed-globose, flattened apically 2. *M. gummifera*.
2. Juice of the tubercles *not* milky; stem cylindroid to ovoid, *not* markedly flattened apically (3)
- 3(2). Spines not hooked (4)
3. Spines [that is, one or more central(s) but not the radials] hooked (6)
- 4(3). Radial spines flexible, hairlike, turning irregularly; central spines 8 to 10, red, puberulent 3. *M. prolifera*.
4. Radial spines not flexible or hairlike; central spines *not both red and* puberulent (5)
- 5(4). Spines 40 or commonly 50 to 80 per areole, white, in several similar series; stem globose, not more than 38 mm. in diameter; flowers rotate, 9-12 in diameter; petaloid perianth parts white with red midstripes ... 4. *M. lasiacantha*.
5. Spines 34 to 48 per areole, clearly and sharply differentiated into central and radial series; stems cylindroidal or globose, but (if globose) 50-100 cm. in diameter at maturity; flowers campanulate or funnellform; petaloid perianth parts pink or reddish-purple 5. *M. Pottsii*.
- 6(3). Only 1 (of 1 to 3) central spines hooked and dark reddish-brown, any others short, pale and not hooked; radial spines 15 to 35 per areole, 6-10.5 mm. long; seed smooth, shiny, the reticulum inconspicuous; petaloid perianth parts purplish-pink, lanceolate, 4-7 mm. broad; fruit to about 6 mm. in diameter 6. *M. Grahamii*.
6. Central spines all (3 or rarely 2) at maturity hooked, dark-reddish-brown; radial spines 10 to 12, 12 mm. long; seed with prominent pits in the reticulate pattern; petaloid perianth parts pinkish-brown or green, linear-lanceolate, 2-3 mm. broad; fruit to 25 mm. in diameter 7. *M. Wrightii*.

1. *Mammillaria longimamma* DC. Stems numerous, forming dense mounds or clumps, cylindroid, about 5 cm. long, 25-62 mm. in diameter; tubercles soft, mammiform-cylin-

droid, protruding 12-25 mm.; central spines reddish-tan, 1 to 4 per areole, straight, minute, 1-3 mm. long, 0.25 mm. in diameter, long-conical; radial spines gray, 12 to 14 per areole, 6-9 mm. long, slender, 0.1 mm. in diameter; flower 2.5-5 cm. in diameter; floral tube funnellform, constricted above the ovary; petaloid perianth parts yellow.

Var. *sphaerica* (Dietr.) K. Brandeg. Tubercles 12-25 mm. long; radial spines 12 to 14, 6-9 mm. long, *glabrous*; central spines 1 to 4, *glabrous*. Near sea level, Tex. from Val Verde Co. to Nueces and Cameron cos.; also n. Mex.

2. *Mammillaria gummifera* Engelm. Stem usually solitary, turbinata to subglobose, the portion above ground flat, depressed or shallowly convex, 7.5-10 or 15 cm. in diameter; tubercles subconical to subpyramidal, protruding 9-12 mm.; central spines brown, reddish-brown or tan, 0, 1 or 2 per areole, porrect, straight, 3-9 mm. long, 0.25-0.5 mm. in diameter; radial spines tan to brown or nearly white, 6 to 22 per areole, 6-13.5 mm. long; flower 1.2-3 cm. in diameter; petaloid perianth parts pink, white or cream-color; fruit red; seeds brown, rugose-reticulate, 1 mm. long.

Var. *applanata* (Engelm.) L. Benson. Stem apex flattened to concave; tubercles subconical; central spine 1, 6-7.5 mm. long; radial spines 10 or 14 to 22, 7.5-9 mm. long, 0.2 in diameter; flower pink to nearly white or cream-color, to 19 mm. in diameter. Ariz., N.M. and Tex.; also Mex.

Var. *hemisphaerica* (Engelm.) L. Benson. PICHILINGA. Stem apex hemispheroidal, with a smooth appearance; tubercles conical; central spine 1, 3-4.5 mm. long; radial spines 7 to 12 or 14, 6 mm. long, 0.3 mm. in diameter; flowers cream-color to pinkish, to 25 mm. in diameter. Tex. from Jim Hogg and Starr cos. to Nueces and Cameron cos.; also Tam. and N.L.

Var. *meiacantha* (Engelm.) L. Benson. Stem apex hemispheroidal; tubercles subpyramidal; central spine 0 or 1, 3-6 mm. long; radial spines 6 to 9, 7.5-10.5 mm. long, 0.5 mm. in diameter; flower pink or pink-and-white, 2.5-3 cm. in diameter. Ariz., N.M. and Tex. w. of the Pecos River.

3. *Mammillaria prolifera* (Mill.) Haw. Stems forming mounds, cylindroid to short-ovoid, 2-5 or 7.5 cm. long, 12-25 or 62 mm. in diameter; tubercles mammiform, protruding 4.5-6 mm.; spines obscuring the stem, the intermingling hairs nearly as long; central spines red, puberulent, 8 to 10 per areole, straight, 6-9 mm. long, 0.1 mm. in diameter; radial spines white, 30 to 60 per areole, spreading irregularly, capillary, winding and twisting, as long as the centrals; flowers closed-campanulate, 12 mm. in diameter; petaloid perianth parts dirty-yellow to whitish-yellow, or reddish or pink-and-yellow; fruit red; seeds black, reticulate-pitted, 1 mm. long.

Var. *texana* (Engelm.) Borg. Stem 12-25 mm. in diameter; central spines 8 to 10, with dark-brown tips; flower almost white to salmon-yellow or partly reddish or pink-and-pale-yellow; fruit 9-12 mm. long. Grasslands, s. Tex. from Val Verde Co. to Bexar and Hidalgo cos.; also n. Mex.

4. *Mammillaria lasiacantha* Engelm. Stem(s) turbinata, 2-3.8 or 10 cm. long; tubercles protruding about 3 mm.; spines obliterating the stem, white, in several series, the number per series decreasing upward, about 40 to 80 per areole, straight, to 3 mm. long, 0.1 mm. in diameter, white-pubescent or *glabrous*; flower rotate, 9-12 mm. in diameter; petaloid perianth parts each white with a red midstripe; fruit red; seed brown, covered by some dark-gray or black, reticulate-pitted, 1 mm. long. Limestone in the Trans-Pecos desert at 900-1,300 m.; also N.M.

Mammillaria lasiacantha is confused with *Epithelantha micromeris*. Flowers of *Mammillaria* are between tubercles away from the stem apex. Those of the *Epithelantha* are on the apices of newly-forming tubercles at the stem apex. In *Mammillaria lasiacantha* the spines remain intact, but in *Epithelantha* after a year or so they disarticulate near the middles. Thus those of the older areoles on the sides of the stem appear shorter than those in a tuft near the growing point.

5. *Mammillaria Pottsii* Engelm. Stems in clusters, cylindroid or somewhat clavate, 7.5-10 cm. long, 2-2.5 or 4.4 cm. in diameter; tubercles protruding 3 mm.; spines obscuring the stem; central spines pale-tan, in one or two series, the upper spines long and purplish-tipped, curving upward, the central spines (altogether) 7 to 11 per areole, the principal central 9-12 mm. long, 0.3 mm. in diameter; radial spines pale-tan, 27 to 37 per areole, porrect; flower campanulate, 6 mm. in diameter; petaloid perianth parts reddish-purple;

fruit red; seed very dark-brown, deeply reticulate-pitted, 1 mm. long. Gravelly areas in the desert at 750-900 m. in Presidio and Brewster cos.; also Chih. to N.L. and Zac.

6. *Mammillaria Grahamii* Engelm. Stems solitary or little-branched, ovoid to spheroid, 5-7.5 or 10 cm. long, 44-62 or 112 mm. in diameter; tubercles protruding 6-12 mm.; areoles elliptic; central spines dark-reddish-brown or red to nearly black, rarely 2 or commonly 3 or 4 per areole, the major one (central in the areole) with a hook about 1.5 or rarely 2 mm. broad, this spine 12-25 mm. long, the upper marginal centrals much shorter, less deeply colored and straight; radial spines white, 20 to 35 per areole; flower 2-3 or 4.4 cm. in diameter; petaloid perianth parts about 10, rose-purple or the margins pale-pink, lanceolate or oblanceolate, 4-8 mm. broad, blunt, entire; stigmas green or creamy-green, about 7 to 10, 2 or 3-6 mm. long, slender; fruit red, to 6 mm. in diameter; seed black, smooth and shining, the pits occupying less space than the reticulum between pits, 1 mm. long. Grasslands at 900-1,500 m. in El Paso Co.; Ariz., N.M. and Tex.

7. *Mammillaria Wrightii* Engelm. Stem solitary, globose or depressed-globose to turbinate, 3.8-10 cm. long, 4-7.5 cm. in diameter; tubercles protruding 3-4.5 mm.; areoles elliptic; central spines dark-reddish-brown, 3 (rarely 2) per areole, spreading, all somewhat curved and apically hooked, equal, about 25 mm. long, 0.2-0.3 mm. thick; radial spines tan, becoming gray, about 10 to 17 per areole; flower 3-4.4 cm. in diameter; petaloid perianth parts about 20, pink or pink-and-tan or sometimes tan or green, lanceolate-linear; stigmas green, 8 to 10, 2-5 mm. long; fruit red, to 25 mm. in diameter; seed brown, with the reticulum occupying less space than the pits, 1.5 mm. long. Gravelly soils at 1,500-2,400 m. in El Paso Co. and the Panhandle; Ariz., N.M. and Tex.

5. LOPHOPHORA COULT

Stems solitary to numerous, short-cylindroidal or hemispheroidal, 25-75 mm. long, 5-10 cm. in diameter; ribs commonly about 8; leaves not discernible; areoles nearly circular, with long tufts of hairs; spines none in the mature plant, bristlelike in the seedling; flowers on the new growth at the apex of the stem, each at the apex of a new tubercle next to the spine-bearing part of the areole; flower 12-25 mm. in diameter; floral tube above the ovary funnellform, pink; fruit red, fleshy, bare, elongate, clavate or nearly cylindroidal, 12-19 mm. long; seed black, of the *Cereus* type, papillate, longer than broad (hilum to opposite side), 1.3 mm. long; hilum obviously basal; cotyledons accumbent, not foliaceous.

One species near the Rio Grande in Texas to the Mexican Plateau. The plant is narcotic, and it has been used by Indians in their religious ceremonies to produce color hallucinations.

1. *Lophophora Williamsii* (Lem.) Coult. PEYOTE. Stems glaucous-green; petaloid perianth parts pink in the middles, pale to nearly white at the margins. Limestone or partly limestone soils in the desert and brushlands at 150-1,200 m. near the Rio Grande from Presidio Co. to Starr and Jim Hogg cos.; s. to S.L.P. and Qro.

6. FEROCACTUS BRITT. & ROSE BARREL CACTUS

Stems unbranched or branched (especially after injury to the terminal bud), cylindroid to ovoid or depressed-globose, 1.5-30 dm. long, 0.75-4.5 or 6 dm. in diameter; ribs 13 to 30; leaves not distinguishable; areoles circular to elliptic; spines annulate or smooth, red, pink, white, tan, brown or yellow, or becoming gray in age; central spines 4 or rarely 1 or 8, straight, curved or hooked, to 16.2 cm. long, 0.5-4 mm. in diameter, acicular to subulate; radial spines either colored like the central or more often lighter or white, 6 to 20 per areole, straight or curved; flower on the new growth of the current season near the apex of the stem and on the apex of a tubercle adjacent to the spine-bearing part of the areole; floral tube above the ovary obconical to barely funnellform; fruit fleshy, with numerous or sometimes only 10 to 15 broad scales, with the floral tube persistent, opening by a short crosswise or lengthwise slit; seeds black, finely reticulate-pitted or papillate, longer than broad (hilum to opposite side), 1-3 mm. long.

Twenty or thirty species from California to Texas and Mexico.

1. Central spines 4, cross-ribbed, 2 mm. or more broad; stem 6-24 dm. long, 30-60 cm. in diameter; fruit yellow, the rind thick, the pulp not very juicy; radial spines ashy-gray, flexible, winding in and out 1. *F. Wislizenii*.
1. Central spines *not* cross-ribbed or inconspicuously so, slender, 1.2 mm. or less in diameter; stem rarely more than 3 dm. long, mostly 5-15 cm. in diameter; fruit green or red, the rind thin, the pulp juicy; radial spines brown to straw-color or white, stiff, straight (2)
- 2(1). Fruit green, broadly ellipsoidal, 3 cm. long, with about 30 or 40 scales; seeds minutely pitted; stems to 30 cm. or reportedly 60 cm. long, to 15 cm. in diameter; central spines 4 or up to 8, to 100 or 162 mm. long and 1.2 mm. broad 2. *F. hamatacanthus*.
2. Fruit red, spheroidal, 8-12 mm. in diameter, with 10 or 15 scales; seeds minutely papillate; stems 4-10 or 20 cm. long, 4-5 cm. in diameter; central spine 1 or with 2 or 3 accessory ones, 12-38 mm. long, 0.5-0.7 mm. in diameter or broad 3. *F. setispinus*.

1. *Ferocactus Wislizenii* (Engelm.) Britt. & Rose. SOUTHWESTERN BARREL CACTUS. Stem massive, cylindroid or ovoid, 6-16 or 30 dm. long, 3-4.5 or 6 dm. in diameter; ribs 20 to 28; central spines red, colored ashy-gray, 4 per areole, strongly cross-ribbed, the lower ones hooked, to 4-5 cm. long, 1.5-2 mm. broad, flattened; radial spines ashy-gray, 12 to 20 per areole, spreading, slender, curving irregularly, not cross-ribbed; flower 4.4-6.2 mm. in diameter; petaloid perianth parts orange-yellow; fruit yellow, barrel-shaped, with numerous nearly circular shallowly fimbriate scales, 3-4.4 cm. long; seed minutely reticulate, 2-2.5 mm. long. Rocky, gravelly or sandy soils in deserts or grasslands at 300 or 600-1,350 or 1,670 m. in El Paso Co.; Ariz., N.M., Tex., Sin. and Chih.

2. *Ferocactus hamatacanthus* (Mühlenpfordt) Britt. & Rose. TURK'S HEAD, BIZNAGA DE LIMILLA. Stems of mature plants ovoid or ovoid-cylindroid, 1.5-3 or 6 dm. long, 7.5-15 cm. in diameter; ribs about 12 to 17, thin; central spines straw-color to brown, 4 or up to 8 per areole, the lower (largest) porrect, annulate, hooked, nearly straight to flexuous, the others straight, 3 or 5.6-10 or 8.7 cm. long, 0.5 or 1-1.2 mm. in diameter or broad, acicular or subulate; radial spines usually brown or straw-color, 8 to 20 per areole; flower 64-75 mm. in diameter; petaloid perianth parts yellow, with red bases; fruit green, fleshy and juicy, with 30 to 40 scales; seed finely pitted, 1.4-1.6 mm. long. Juvenile plants have central spines 3.1-5 cm. long and only 8 to 11 radials.

Var. *hamatacanthus*. Ribs not much-compressed; central spines angled or flattened, twisting but not flexuous, 6.2-10 cm. long, 1-1.2 mm. in diameter; flower 64-75 mm. in diameter; fruits 3 cm. long; seeds finely pitted. Desert and grassland at 750-1,500 m. from El Paso Co. to Webb Co.

Var. *sinuatus* (Dietr.) L. Benson. Ribs strongly compressed; central spines (lower one) strongly flattened, markedly flexuous, 38-94 mm. long, 1 mm. broad; flowers and fruits smaller than in var. *hamatacanthus*; seed finely pitted. From the Pecos River and Rio Grande to San Patricio Co.; also n.e. Mex.

3. *Ferocactus setispinus* (Engelm.) L. Benson. HEDGEHOG CACTUS. Stems green, ovoid or cylindroid, 3.8-10 or 20 cm. long, 3.8-5 cm. in diameter; ribs about 13, narrow; chief central spine straw-color or reddish-brown with a lighter tip (there being, also, 1 or 2 or 3 upper straight ones per areole), strongly hooked, smooth, finely scaberulous-canescens, 12-38 mm. long, 0.5-0.7 mm. in diameter, usually acicular; radial spines straw-color or white or brown, 12 to 15 per areole, nearly straight; flower 4-5.6 cm. in diameter; petaloid perianth parts clear-yellow, with red bases; fruit red, with about 10 to 15 scales; seed minutely papillate, 1-1.4 mm. long. About 300 m. or less from Val Verde and San Saba cos. to Travis, Refugio and Cameron cos.; also adj. Mex.

7. ECHINOCACTUS LINK & OTTO

BARREL CACTUS

Stems branching or unbranched, 5-60 cm. long, 5-30 cm. in diameter; ribs 8 to 27; leaves not discernible; areoles nearly circular to elliptic; central spines red, sometimes 0 or 1 to 4 per areole, straight or curving, 25-75 mm. long, 1.5-9 mm. broad, nearly

acicular to subulate; radial spines similar to the central but smaller, 5 to 11 per areole; flowers on the new growth near the apex of the stem, at the apex of the tubercle adjacent to the spine-bearing part of the areole; flower 4-6.8 cm. in diameter; floral tube above the ovary obconical to slightly funnellform; sepaloid perianth parts aristate- or spinose-tipped; fruit dry or fleshy, with scales and with long hairs from beneath them; seed black or brown, reticulate, usually broader than long (hilum to opposite side); hilum appearing "lateral" or oblique; cotyledons accumbent, *not* foliaceous.

Twelve or more species from California to Texas and Querétaro.

1. Stem *not* bearing spines, the surface with minute scales with long woolly hairs on the margins; seed brown, the hilum enclosed in a chamber formed from the elaborated margin of the seed coat, the funiculus entering the chamber through a pore
 3. *E. asterias*.
1. Stem bearing spines and *not* scales; seed black, the hilum depressed but *not* enclosed (2)
- 2(1). Fruit densely woolly after drying at maturity, long-persistent among the spines, dehiscent by an apical pore 1. *E. horizontalonius*.
2. Fruit becoming naked, scarlet, at first pulpy and juicy, but drying and bursting irregularly 2. *E. texensis*.

1. *Echinocactus horizontalonius* Lem. TURK'S HEAD, DEVIL'S HEAD, MANCA CABALLO. Stem solitary, depressed-globose to ovoid or sometimes columnar, glaucous, 1-1.5 or 3 dm. long, 1-1.5 dm. in diameter; ribs 7 to 13, commonly 8; central spine pale-gray or sometimes black, with under-layers of red or red-and-yellow, 3 per areole, 1 curving gradually downward, 2.5-3 cm. long, 2-3 mm. broad, somewhat flattened; radial spines gray, 5 or 6 to 8 per areole, curving slightly outward; flower 5-6.4 cm. in diameter; petaloid perianth parts pink; fruit at first juicy but drying at maturity, densely covered with white soft woolly hairs; seed black, papillate and reticulate, 3 mm. broad. Limestone at 900-1,650 m. in the Trans-Pecos; Tex. and N.M. s. to S.L.P.

2. *Echinocactus texensis* Höpffer. HORSE CRIPPLER, DEVIL'S HEAD, DEVIL'S PINCUSHION, MANCA CABALLO. Stems hemispheroidal, 1.25-2 dm. long, to 3 dm. in diameter; ribs 13 to 27; spines red but basally whitened, strongly cross-ribbed, stout and rigid; central spine 1 per areole, curving rigidly downward and exceeding the radials, 3-7.5 cm. long, 3-9 mm. broad, subulate, flattened but angular, tapering; radial spines 6 or sometimes 5 to 7 per areole; flower 5-6 cm. in diameter; petaloid perianth parts with the midribs pale-purple to violet, basally scarlet, then orange and distally pale-pink to white; fruit red, fleshy, the scales more or less deciduous; seed black, finely reticulate, 2.5 mm. broad. *Homalocephala texensis* (Höpffer) Britt. & Rose. Sea level to 1,100 m., from Brewster Co. to Howard, Young, Tarrant, Travis, Refugio and Cameron cos.; also N.M., Coah., N.L. and Tam.

3. *Echinocactus asterias* Zucc. STAR CACTUS. Stem with a covering of white or yellowish circular scales, 25-75 mm. long, to 75 mm. in diameter; ribs usually 8, separated by narrow grooves; areoles bearing many hairs; spines none; flower 3.8-5 cm. in diameter; petaloid perianth parts yellow; fruit green or pink but obscured by the white woolly hairs from the areoles; seed brown, shiny, finely reticulate, the basal part an amazing collar surrounding the hilum, the rim turned inward and forming a membranous covering around the threadlike funiculus, the seed proper 2 mm. long and 3 mm. broad. Grasslands and brushlands at low elev. in Starr Co.; also N.L. and Tam.

8. EPITHELANTHA BRITT. & ROSE

BUTTON CACTUS

Stems unbranched or branching and in clumps, ovoid-cylindroid to cylindroid, 25-62 mm. long; tubercles separate; leaves not discernible; areoles nearly circular; spines in the upper portion of the areole longer, making a tuft in the depression at the apex of the stem, ultimately breaking at the middles, the terminal tuft thereby giving way to "shorter" spines on the sides of the stem, 20 to 100 per areole, in 2 to 5 series, straight, 3-6 mm. long; flowers on the new growth near the apex of the stem, each at the apex of a tubercle adjacent to the spine-bearing part of the areole; floral tube above the ovary funnellform; fruits red or some small and colorless and with only 1 to 5 (instead of 5 or 6 to 11) seeds;

seeds black, impressed-reticulate and sometimes also papillate, broader than long (hilum to opposite side); hilum appearing "lateral;" cotyledons accumbent, not foliaceous.

A few species from Arizona to Texas and northern Mexico.

1. Spines in 2 or sometimes 3 series of about 20, 6 mm. long; flower 3-4.5 mm in diameter; petaloid perianth parts semicircular to obdeltoid, 1 mm. long; stamens 10 to 15; stems usually irregularly short-cylindroid to ovoid, the spines giving the stem a relatively rough irregular surface appearance1. *E. micromeris*.
1. Spines in 4 or 5 series of about 25 or 28 (outer series) to about 10 (inner series); flower 10-12 mm. in diameter; petaloid perianth parts bluntly oblanceolate, 9 mm. long; stamens 35 to 40; stems cylindroidal, the spines giving the stem a shining smooth appearance2. *E. Bokei*.

1. *Epithelantha micromeris* (Engelm.) Weber. Stems solitary or sometimes in small clumps, usually irregularly ovoid-cylindroidal, with a slight apical depression, 4-6.2 cm. long, 2.5-6.2 mm. in diameter; spines in 2 series of about 20 (or sometimes with a third series) per areole, accompanied by white woolly hairs, 6 mm. long; flowers 3-4.5 mm. in diameter; petaloid perianth parts pale-pink, approaching obdeltoid, 1 mm. long; stamens about 10 to 15; seed minutely reticulate-impressed, 1.5 mm. broad. Limestone or sometimes igneous soils in the desert and grassland at 1,000-1,500 m., Ariz., N.M. and Tex. from El Paso Co. to Pecos and Val Verde cos. and in Bandera Co.; also n. Mex.

See note under *Mammillaria lasiacantha*.

2. *Epithelantha Bokei* L. Benson. Stems solitary or many, 2.5-5 cm. long, 2.5-5 cm. in diameter; spines white, in each areole in 4 or 5 series of about 25 to 28 (outer) to about 10 (inner), spreading parallel to the stem, 3-4.5 mm. long; flower 10-12 mm. in diameter; petaloid perianth parts pink, bluntly oblanceolate, about 9 mm. long, 3 mm. broad; stamens 35 to 40; seed impressed-reticulate and papillate, 1 mm. broad. Limestone in the desert at 750-1,200 m. in the Big Bend; also adj. Mex.

9. THELOCACTUS (K. SCHUM.) BRITT. & ROSE

Stems solitary or several, hemispheroidal to ovoid or long-ovoid, 7.5-10 or 12.5 cm. long, 5-10 or 12.5 cm. in diameter; ribs 8 to 12; leaves not discernible; areoles nearly circular; spines smooth, straw-color or tinged with pink; central spines 1 to 4 per areole, straight or curved; radial spines 3 to 17 per areole; flowers on the new growth of the current season near the apex of the stem on the upper side of the tubercle next to the spine-bearing part of the areole; floral tube above the ovary obconic to funnelform; fruit dry, with 5 to 20 scales, subcylindroid, the floral tube persistent, the fruit opening diagonally at the base; seeds black, so far as known finely reticulate-papillate, longer than broad (hilum to opposite side), about 1.75 mm. long; hilum obviously basal; cotyledons accumbent, not foliaceous.

A few species in Texas and Mexico.

1. *Thelocactus bicolor* (Gal.) Britt. & Rose. Stems solitary, ovoid or long-ovoid, 0.75-1 or 1.25 dm. long, 5-7.5 or 12.5 cm. in diameter; ribs about 8, the tubercles coalescent basally into the ribs, crowded tightly against each other and separated by only slitlike spaces, protruding 9-12 mm.; areoles circular; spines straw-color or tinged with pink; central spines 4, the upper spreading with the radials, the lower one porrect, straight, 2.5-3 cm. long, 1 mm. broad, flattened; radial spines 10 to 17 per areole, 1-2.5 or 3 cm. long, acicular; flower 5-6.2 cm. in diameter; petaloid perianth parts rose but basally red; fruit green; seed finely reticulate-papillate, obovoid but basally truncate, 2.5 mm. long.

Var. *Schottii* (Engelm.) Krainz. Spines tinged with pink, the upper flattened radial spines straw-color or white; central spines long, to 44 mm. long, carinate; radial spines 15 to 17, the upper flattened ones 2 to 4, to 75 mm. long, 1.5 mm. broad. Gravelly soils at 1,200 m. or less, from the Big Bend to Starr Co.; also Tam.

Var. *flavidispinus* Backeberg. Spines all straw-color or with a slight tingle of pink; central spines short, the longest (upper) 2 cm. long; radial spines 12 to 14, the upper flattened ones 1 or 2 (instead of 2 or 3), to only 38 mm. long, 0.5 mm. broad. Hills at about 1,200 m. and lower in n.e. Brewster Co. and Starr Co.

10. NEOLLOYDIA BRITT. & ROSE

Stems branched or unbranched, ovoid or cylindroid, 5-15 or 38 cm. long, 25-75 or 125 mm. in diameter; ribs 8 to 21, the tubercles separate, not coalescent and not forming ribs; leaves not discernible; areoles nearly circular to elliptic; spines smooth, black to dark-brown or tan, chalky-blue, straw-color, purplish or pink, sometimes dark-tipped, becoming gray or black in age; central spines 1 to 8 per areole, straight or rarely (in Mexico) curved or almost hooked, 12-44 mm. long, 0.4-1.5 mm. in diameter, acicular or subulate; radial spines white or similar to the central, 3 to 32 per areole; flower on the new growth near the apex of the stem on the upper side of a tubercle in a felted area distant from the spine-bearing part of the areole and connected with it by an isthmus running from half to the full length of the tubercle, 25-75 mm. in diameter; floral tube above the ovary funnellform to obconical; fruit dry, with a few or up to 20 membranous scales, dehiscent basally or in species occurring elsewhere by 1 to 3 longitudinal slits; seed black, reticulate, reticulate-papillate or papillate, either broader than long or longer than broad (hilum to opposite side), 1.5-2.5 mm. in greatest dimension; hilum either obviously basal or appearing "lateral;" cotyledons accumbent, *not* foliaceous.

Twelve or fifteen species from Arizona to Texas and San Luis Potosí.

1. Lower central spine longer than the others, the central spines black or dark-brown; stems branching and forming clumps, green; seed longer (hilum to opposite point) than broad, the hilum obviously basal 1. *N. conoidea*.
1. Lower central spine shorter than the others, the central spines dull-tan tipped with chalky-blue or blue-brown or pinkish or grayish straw-color; stems (so far as known) unbranched; seed broader than long (hilum to opposite point), the hilum appearing "lateral" or perhaps transitional (2)
- 2(1). Central spines usually grayish or straw-color with the upper parts pink or red or sometimes all red; stem green; lower porrect central spine often very short but sometimes to 22 mm. long; seed 2 mm. broad 4. *N. intertexta*.
2. Central spines dull-tan, tipped with chalky-blue or blue-brown; stem glaucous (3)
- 3(2). Radial spines 12 to 14 per areole, not pectinate, spreading irregularly at low angles, blurring the stem; central spines similar to the radial, 4 (or possibly 6, with 2 additional ones above), the upper ones about one fourth longer than the lower porrect one; seed 2 mm. broad 2. *N. Warnockii*.
3. Radial spines 26 to 32 per areole, pectinate, obscuring the stem; central spines much thicker and longer than the radials, 3, the upper ones about three times as long as the lower porrect one; seed 1.5 mm. broad 3. *N. mariposensis*.

1. *Neolloydia conoidea* (DC.) Britt. & Rose. Stems green, not bluish, solitary to several or many, ovoid to cylindroid, 7.5-10 cm. long, 25-62 mm. in diameter; ribs slightly developed; tubercles protruding 6-12 mm.; central spines black or dark-brown, mostly 4 per areole, the lower principal one turned slightly downward, straight, 2-3 cm. long; radial spines white, 15 to 28 per areole, parallel to the stem; flower 4-6 cm. in diameter; petaloid perianth parts magenta or purplish; seed longer than broad. Limestone habitats in Brewster, Pecos and Terrell cos.; also n. Mex.

2. *Neolloydia Warnockii* L. Benson. Stems blue-green, solitary, ovoid to long-ovoid, 7-11.2 cm. long, 5-7.5 cm. in diameter; ribs 13 to 21; tubercles protruding 9 mm.; central spines dull-tan but the tips chalky-blue or partly brown, 4 per areole or perhaps with 2 or more above the upper median one, straight, the lower porrect; radial spines like the central but the dark tips shorter and the diameter a little less, 12 to 14 per areole, spreading rather irregularly; flower 25 mm. in diameter; petaloid perianth parts pink; fruit green; seed black, papillate in a reticulate pattern, 1.5 mm. long, 2 mm. broad; hilum appearing "lateral." Limestone in the desert at 560-900 or 1,200 m., from Hudspeth to Culberson and Brewster cos.

3. *Neolloydia mariposensis* (Hester) L. Benson. Stems blue-green, ovoid- or obovoid-cylindroid, 6.2-10 cm. long, 4-6 cm. in diameter; ribs 21, the tubercles of greater height than the rib beneath them; tubercles protruding 3 mm.; central spines dull-tan with chalky-blue or partly brown tips, 2 to 4 per areole, the lower one turned and curving downward, one third as long but similar to the upper 1 to 3, these straight, 1.5-2 cm.

long; radial spines ashy-white, 26 to 32 per areole; flower to 38 mm. in diameter; seed black, papillate in a reticulate pattern, 1.3 mm. long, 1.5 mm. broad; hilum "lateral" but transitional to the obviously basal type. Limestone in the desert at 750-1,000 m., Presidio Co.; also cen. Coah.

4. *Neolloydia intertexta* (Engelm.) L. Benson. WHITE VIZNAGITA. Stems solitary, elongate-ovoid to cylindroid, 5-15 cm. long, 4-7.5 cm. in diameter; ribs deeply and usually sharply indented between tubercles, the tubercles protruding 3 mm. above the rib; spines dense; central spines pinkish or all but the tips grayish-straw-color, usually 4 per areole, the three upper ones appearing to be radials, 15-22 mm. long, the lower (obviously central) one porrect, 1-3 or up to 15-22 mm. long, elongate-conical; radial spines 13 to 20 per areole, 9-15 or 20 mm. long; flower 2.5-3 cm. in diameter; petaloid perianth parts pink or pale pinkish-white on the margins; fruit green, drying to tan or brown; seed black, minutely and regularly papillate-reticulate, 1.5 mm. long, 2 mm. broad.

Var. *intertexta*. Stem ovoid or obovoid to cylindroid, 5-7.5 or 15 cm. long; upper central spines and radial spines appressed against the stem, shorter than in var. *dasyacantha*, 12-15 mm. long, stouter than in var. *dasyacantha*, to 0.5 mm. in diameter; lower central spine porrect, 1-3 mm. long, elongate-conical, much shorter than the other centrals. Limestone in grasslands at 1,200-1,500 m., Ariz., N.M. and s. in Tex. to Jeff Davis and Brewster cos.; also Son. and Chih.

Var. *dasyacantha* (Engelm.) L. Benson. Stem becoming elongate-ovoid to cylindroid, 7.5-15 cm. long; upper central spines and radial spines *not* strongly appressed against the stem, to 15-20 or 40 mm. long; lower central spine 15-20 mm. long. Limestone in the desert at 900-1,500 m., N.M. and Tex. in El Paso Co.

11. ANCISTROCACTUS BRITT. & ROSE

Stem solitary or rarely with a few branches, globose in young plants and obovoid, ellipsoid, obovoid-cylindroid, obconical, turbinate or globose in older plants; ribs clear in older plants, the bases of the tubercles confluent; leaves not discernible; central spine(s) on juvenile stems 1 per areole, on mature stems 3 or 4, the lower one hooked, the others straight and turned upward; radial spines 6 to 22, straight or some of the lower ones hooked; flower on a new tubercle near the stem apex; flower-bearing portion of the areole on a young stem nearly circular to elliptic and adjacent to the spine-bearing portion of the areole at the apex of the tubercle, the flowers of later seasons lower and lower on the new tubercles and ultimately from their bases, the narrow connecting grooves becoming longer and longer; flower 2.5-3 cm. in diameter; floral tube obconic to funnellform; petaloid perianth segments green to cream-color, pale-yellow, red or rose-purple; fruit green or red, fleshy, indehiscent, bearing 1 or commonly 2 to 13 or numerous scales; seed dark-brown or black, finely papillate, broader than long or longer than broad (hilum to opposite side); hilum obviously basal or appearing "lateral," cotyledons accumbent, not foliaceous.

Four species in southern Texas and Mexico.

1. Radial spines (some longer ones) hooked; principal central spine (the lower hooked one) 50-75 or 112 mm. long; petaloid perianth parts red; fruit bearing numerous scale leaves, red, fleshy, thick-walled, juicy; seed longer than broad, therefore the hilum obviously basal3. *A. uncinatus*.
1. Radial spines *not* hooked; principal central spine (the lower hooked one) 12-44 mm. long; petaloid perianth parts (so far as observed) cream-color to yellow or greenish-yellow or (reportedly) rose-purple; fruit bearing 1 or commonly 2 to 13 scale leaves, green or red-tinged, thin-walled, not juicy; seed broader than long, the hilum appearing "lateral" (2)
- 2(1). Spines finely scaberulous-canescens; radial spines 7 to 9 per areole, spreading rather irregularly; stem almost flat-topped, turbinate or obconical, arising only slightly above ground level1. *A. Tobuschii*.
2. Spines glabrous; radial spines 1 to 22 per areole, spreading rather uniformly; stem at maturity obovoid-cylindroid, elongate (beginning to flower while it is still juvenile and obovoid), rising conspicuously above ground level2. *A. Scheeri*.

1. *Ancistrocactus Tobuschii* W. T. Marsh. Obscure cactus with normally solitary stems, these obconical or turbinate, 3.8-5 cm. long, 3.8-5 cm. in diameter; roots fibrous; central spines at first light-yellow with red tips, changing to gray, 3 per areole, the upper two straight and turned upward, the lower one hooked and porrect, to 22 mm. long and 0.4 mm. broad, subulate; radial spines like the central but small, 7 to 9 per areole, acicular; flower 3-3.8 cm. in diameter; fruit green or tinged with red, with apparently only 1 to 3 scales; seed black, finely papillate, 1.5 mm. long, 1.5 mm. broad or slightly more. Limestone at 450 m. in Bandera Co.

2. *Ancistrocactus Scheeri* (Salm-Dyck) Britt. & Rose. Stems solitary, ellipsoid to nearly globose or obovoid or elongate-obovoid, 2.5-10 or 15 cm. long, 2.5-5 or 10 cm. in diameter; roots fibrous or tuberous; principal central spines ventrally pale-grayish or whitish and dorsally black-yellow and on the curve of the hook, porrect; *juvenile plants* with the longer principal central spines 1-1.2 cm. long and upper central spines mostly 0 to 2, but sometimes 3, pale-gray, the middle one (if present) usually short and weak; *mature plants* with the longer principal central spines 25-44 mm. long and the upper central spines whitish, usually 3, flattened, middle one 1-1.5 cm. long but weak; flower 2.5-3 cm. in diameter; petaloid perianth parts greenish-yellow; fruit green, somewhat fleshy but thin-walled and finally dry at maturity, with 8 to 13 scales; seed brown, finely papillate, 1.5 mm. long, 2 mm. broad. *A. brevihamatus* (Engelm.) Britt. & Rose. Brushy areas in grasslands at low elev. from Val Verde Co. to Jim Wells and Hidalgo cos.; also N.L. and Tam.

3. *Ancistrocactus uncinatus* (Gal.) L. Benson. Stems unbranched, cylindroid-ovoid to ovoid, 7.5-15 cm. long, 5-7.5 or 10 cm. in diameter; ribs present but the constrictions between tubercles slitlike; central spines light-colored, tannish-white to straw-color or pinkish, the principal one turned upward, hooked, 5-7.5 or 11.2 cm. long, 1 or 1.3 mm. broad, somewhat flattened; lower radial spines reddish or reddish-tan, some hooked; flower 2.5-3 cm. in diameter; fruit red, fleshy at maturity, with numerous scales; seed minutely papillate above, 1.5 mm. long, 1 mm. broad; hilum obviously basal, surrounded by a broad border.

Var. *Wrightii* (Engelm.) L. Benson. Upper sepaloid perianth parts obtuse; petals obtuse to acute. Limestone in the desert at 1,000-1,200 m., from El Paso Co. to Crockett, Starr and Victoria cos.; also N.M. and Chih.

12. CORYPHANTHA (ENGELM.) LEM.

Stems solitary or branching, sometimes forming mounds of 200 or more, subglobose to cylindroid, 2.5-10 or 12.5 cm. long, 25-75 mm. in diameter; tubercles separate; leaves not discernible; areoles circular to elliptic; spines smooth, white to gray, pink, yellow, brown or black; central spines 1 to 10 or more per areole, grading into the radial, straight, curved, hooked or somewhat twisted, acicular or sometimes subulate; radial spines 5 to 40 per areole; flower on the new growth near the apex of the stem at the base of the upper side of a tubercle distant from the spine-bearing part of the areole and connected by a narrow isthmus (on immature stems and in *Coryphantha macromeris* up to mid-level on the tubercle), 1.2-5 cm. in diameter; floral tube above the ovary funnelliform; fruit fleshy, green or red at maturity, thin-walled, without surface appendages; seed tan, brown or black, smooth and shining or punctate or reticulate, usually but not necessarily broader than long (hilum to opposite side), 1-2 mm. in greatest dimension; hilum usually appearing "lateral" but sometimes obviously basal or "oblique;" cotyledons accumbent, not foliaceous.

Twenty or thirty species from Alberta to Mexico.

1. Spines cylindroid, each with an abruptly acute apex, the upper 3 large ones of the innermost series strongly bulbous-based, up to 4.5 mm. long, the spines about 20 in 2 or 3 series, gradually diminishing in size, especially in the upper part of the outer series; stems ovoid, about 1.2-2 or 2.5 cm. long 1. *C. minima*.
1. Spines *not* cylindroid, the apices *not* abruptly acute (2)

- 2(1). Mature fruit green, commonly clavate or cylindroid or ellipsoid, but in some species unknown; seeds usually brown, rarely black, usually though not always broader than long, the hilum usually appearing "lateral" but sometimes obviously basal; central spines usually present and different from the radials (3)
2. Mature fruit red (9)
- 3(2). Fruit bearing a few scales; flower at mid-level on the tubercle (even in mature plants) 2. *C. macromeris*.
3. Fruit bearing no scales; flower (except on a juvenile stem) at the base of the ventral side of the tubercle (4)
- 4(3). Tubercles protruding 2.5-3.8 cm., conspicuous; central spines 2.5-3.8 cm. long, 1-1.5 mm. in diameter, straw-yellow with dark-red tips 3. *C. Scheeri*.
4. Tubercles protruding not more than 1.2 or rarely 2 cm.; central spines up to 1.7 cm. long (if the bases are as much as 1-1.5 mm. in diameter) (5)
- 5(4). Lower central spine porrect, either shorter than the upward-directed upper ones or lacking; sepaloid perianth parts ciliate-fimbriate; seeds reticulate (unknown in *C. Hesteri*) (6)
5. Lower central spine porrect, longer than the upward-directed upper ones; sepaloid perianth parts not ciliate nor fimbriate (not determined for *C. ramillosa*); seeds smooth and shining, *not* reticulate, sometimes minutely punctate (unknown in *C. ramillosa*) (7)
- 6(5). Longest spines 12-20 or 25 mm. long; radial spines 9-15 mm. long; flower 1.5-2 cm. in diameter; petaloid perianth parts apically mucronate to acuminate or attenuate; stigmas 1.5-3 mm. long 4. *C. vivipara*.
6. Longest spines 9-10.5 mm. long; radial spines 3-9 mm. long; flower 1.5-2 cm. in diameter; petaloid perianth parts apically acute; stigmas about 1 mm. long 5. *C. Hesteri*.
- 7(5). Central spines at first dark-chocolate-brown, the lower porrect principal one remaining so; perianth parts pale-pink to rose-purple, not yellow 6. *C. ramillosa*.
7. Central spines at first pink, yellow or gray, the lower porrect principal one changing (as do the others) to white or light-gray (8)
- 8(7). Flower opening and reopening on two or three days; each petaloid perianth part yellow apically but pink basally, *not* bristle-tipped; seed smooth, not punctate ... 7. *C. sulcata*.
8. Flower opening only once, then for an hour or two; each petaloid perianth part yellow, apically toothed and bristle-tipped; seed smooth but minutely punctate 8. *C. cornifera*.
- 9(2). Fruit globular; central spine(s) lacking or solitary or rarely 2, similar to the radials; seeds black, slightly longer than broad, the hilum obviously basal; flowers yellow or rarely pink 14. *C. missouriensis*.
9. Fruit much longer than its diameter, ellipsoid to clavate or cylindroid; central spines 5 to 11 or in one species 1 to 4 per areole or in another species not differentiated from the radial; flowers pink to white (10).
- 10(9). Seed broader than long, the hilum appearing "lateral," the seed coat brown; stems usually branching (11)
10. Seed longer than broad, the hilum obviously basal, the seed coat brown to black (12)
- 11(10). Radial spines on the upper side of the areole not markedly longer than those on the lower; fruit usually bright-red (though sometimes green); mature stems 2.5-5 cm. in diameter, 7.5-12.5 or 20 cm. long, solitary or forming clumps of several branches 9. *C. strobiliformis*.
11. Radial spines on the upper side of the areole much longer than those on the lower; fruit green at maturity; stems 1.2-2.5 cm. in diameter, 2.5-7.5 cm. long, branching profusely and forming extensive mats 10. *C. Sneedii*.

- 12(10). Spines in several series, not clearly differentiated into centrals and radials, the inner gradually somewhat larger, 30 to 75 per areole; seed black; stems solitary or rarely 2 or 313. *C. Duncanii*.
12. Spines in a series of larger centrals and one of smaller radials, 17 to 38 altogether; seed dark-brown to black (13)
- 13(12). Stems (so far as known) solitary, cylindroid, 2.5 or 4-5 cm. in diameter, 7.5-17.5 cm. long; anthers oblong, twice as long as broad ... 11. *C. dasyacantha*.
13. Stems branching, often profusely so, obovoid, 1.2-2.5 cm. in diameter, 3.8-5 cm. long; anthers ovoid12. *C. Robertii*.

1. *Coryphantha minima* Baird. Stem simple or sparingly branched, ovoid, 1.2-2 or 2.5 cm. long, 12 mm. in diameter; tubercles subcylindroid, protruding 3 mm.; spines about 20 per areole, pale-ashy-gray or sometimes pinkish, in 2 or 3 series, all spreading parallel to the stem, those of the inner series longer and thicker, the 3 largest in the upper part of the areole about 4.5 mm. long, basally bulbous, above the bulb 0.5 mm. in diameter, cylindroidal with an abruptly acute apex. *C. Nellieae* Croizat. Hills, at 1,200-1,350 m., Brewster Co.; endemic.

2. *Coryphantha macromeris* (Engelm.) Britt. & Rose. Stems solitary or forming clumps, cylindroid to elongate-ovoid, 5-15 cm. long, to 5 cm. in diameter; each tubercle prominent and elongate, unlike those of the other species grooved only on the upper half, protruding to 15-25 mm.; central spines black or dark-gray to pale-gray, 4 to 6 per areole, the lower (principal) one a little longer, the upper 3 or 5 less conspicuous, straight or somewhat curved or twisted, up to 2.5-5 cm. long and 1 mm. broad, subulate; radial spines dark- to pale-gray, lighter than the centrals, 9 to 15 per areole, straight to slightly curving; flower 3-4.4 cm. in diameter; petaloid perianth parts reddish-purple to rose; fruit green, the few fimbriate scales with woolly axils.

Var. *macromeris*. Stems green, 10-15 cm. long and 5 cm. in diameter, in clumps to 3 dm. in diameter; tubercles mostly 15 mm. long vertically, 6-9 mm. broad, protruding 15-25 mm. Clay and gravelly soils in the desert at 800-1,350 m., w. of Pecos River and in Reeves Co.; also N.M. and s. to Zac.

Var. *Runyonii* (Britt. & Rose) L. Benson. Stems gray-green, up to 5-7.5 cm. long, 25-38 mm. in diameter, in clumps to 9 dm. in diameter; tubercles mostly to 7.5 mm. long and 4.5 mm. broad, protruding 12 mm. Gravelly and white silt soils at low elev. from Starr Co. and Cameron Co.; endemic.

3. *Coryphantha Scheeri* (O. Ktze.) L. Benson. Stems solitary or sometimes in clusters, ellipsoid, 1-1.75 dm. long, 7.5-10 cm. in diameter; tubercles elongate, prismatic-cylindroid, protruding 25-38 mm.; central spines straw-color with dark-red tips or pink, 1 to 4 or 5 per areole, nearly porrect, to 38 mm. long and 1 or 1.5 mm. in diameter, acicular; radial spines 1 to 4 or 5 per areole; flower 5-7.5 cm. in diameter; petaloid perianth parts yellow or with red streaks; fruit green, fleshy; seed brown or perhaps becoming black, very finely reticulate, 2 mm. long, 3 mm. broad; hilum in the curve. *C. Muehlenpfordtii* (Poselger) Britt. & Rose.

Var. *Scheeri*. Stem solitary; young areoles *not* covered with wool; central spine 1, to 38 mm. long, *not* strongly curved nor hooked; radial spines 8 to 10 or 11, to 2 cm. long; sepaloïd perianth parts with glabrous margins; petaloïd perianth parts yellow with red streaks. N.M. and Tex. near the Pecos River and in the Big Bend; also Mex.

Var. *valida* (Engelm.) L. Benson. Stem solitary; young areoles covered densely with wool; central spines 1 to 4 or 5, one to 38 mm. long, *not* strongly curved and *not* hooked; radial spines 9 or 12 to 16, to 3 cm. long; sepaloïd perianth parts ciliate; petaloïd perianth parts yellow. Ariz. to N.M. and Tex. e. to the Davis Mts.; also Chih.

Var. *uncinata* L. Benson. Stem branching unknown; young areoles covered densely with deciduous wool; central spines 1 to 3 in young plants, 3 and equal in mature plants, 25 mm. long, all strongly arcuate and apically hooked; radial spines about 16, about 25 mm. long; flowers unknown. Near El Paso; endemic.

4. *Coryphantha vivipara* (Nutt.) Britt. & Rose. Stems depressed-globose to ovoid or cylindroid, in some varieties forming clumps of 200 or more, 4-7.5 cm. in diameter; tubercles protruding 6-19 mm.; central spines usually white basally but tipped with pink, red or black, 3 to 10 per areole, spreading at various angles, straight, up to 12-19 or 25 mm. long, 0.3-0.6 mm. in diameter, acicular; radial spines white, 12 to 40 per areole;

flowers in some varieties open only an hour or two on one day in the year but in other varieties often in several crops produced at different times; flower 2.5-5 cm. in diameter; petaloid perianth parts pink, red, lavender or yellow-green; fruit green, fleshy; seed brown, reticulate, 1.2 mm. long, 1.5-2 mm. broad; hilum appearing "lateral."

Var. *vivipara*. Stems depressed-globose to ovoid, 2-2.5 cm. long, 3.8-5 cm. in diameter; central spines 4, the lower one red and dark-colored or basally white; radial spines 12 to 20, white, 1-1.2 cm. long; fruit 1.2-2 cm. long; seed 1.5-1.8 mm. long. Alta. and Ore., e. to Minn., Kan., N.M., Okla. and the n. Tex. Panhandle.

Var. *radiosa* (Engelm.) Backeberg. Stems ovoid to cylindroid, 5-7.5 cm. long, 2-5.6 cm. in diameter; central spines 3 or 4, the lower one pink to red, relatively less prominent among the radials than in var. *vivipara*; radial spines 20 to 40, white to pink, 1.2-2 cm. long; fruit 2-2.5 cm. long; seed 2 mm. long. Incl. var. *neomexicana* (Engelm.) Backeberg, *C. fragrans* Hester, *Mammillaria vivipara* (Nutt.) Haw. subsp. *radiosa* and var. *texana* Engelm. N.M. to Okla. and w. and cen. Tex.

5. *Coryphantha Hesteri* Y. Wright. Stems forming clumps 1-1.5 dm. in diameter, each broadly obovoid to turbinate or subglobose, 2.5-4 or 5 cm. long, 2-3 or 4.4 cm. in diameter; tubercles wide and prominent, protruding 6-9 mm.; central spines white or sometimes red-tipped, 1 to about 4 per areole, all in the upper portion and turned upward, to 1 cm. long, tapering, acicular; radial spines white, 12 to 14 per areole, 3-9 mm. long; flower 1.5-2 cm. in diameter; petaloid perianth parts lavender. Limestone and other soils at 1,200-1,500 m. in n. Brewster Co.; endemic.

6. *Coryphantha ramillosa* Cutak. Stem globular or broadly obovoid, 6-7.5 cm. long, 6 cm. in diameter; tubercles wide and prominent, protruding 12-15 mm.; central spines 4 with 1 to 3 accessory ones above them, straight or somewhat curved, the lower one dark-brown, porrect, 2.5-4 cm. long, the upper 3 nearly white, turned upward, the principal central spine 0.75 mm. in diameter, acicular; radial spines white, 9 to 20 per areole. Limestone in the desert at 750-1,050 m. in Brewster and Terrell cos.; also Coah.

7. *Coryphantha sulcata* (Engelm.) Britt. & Rose. Stems branching, forming clumps, subglobose or obovoid, 7.5-12.5 cm. long and the same diameter; tubercles protruding 12 mm.; spines at first either yellow-and-pink or pink, later gray or overlain by gray or white; central spine(s) 1 or perhaps 2 or 3 per areole, spreading, slightly curving, up to 9-12 mm. long, 0.5 mm. in diameter, acicular; radial spines similar but shorter, 6 to 8 per areole; flower 4-6.2 cm. in diameter; petaloid perianth parts red basally, yellow distally; fruit green, fleshy; seed brown, smooth and shining, 1 mm. long, 2 mm. broad.

Var. *sulcata*. Stem subglobose, 75-125 mm. long, of equal diameter; spines at first yellow-and-pink or pink, later overlain by gray or white, 0.3-0.5 mm. in diameter; flower to 5-6.2 cm. in diameter. Sandy or gravelly soil at low elev. from Wichita and Tarrant cos. to Uvalde, Austin and Duval cos.

Var. *Nickelsiae* (K. Brandeg.) L. Benson. Stem obovoid, about 5 cm. long, 3.8-5 cm. in diameter; spines pink overlain by gray or white, slender, 0.3-0.4 mm. in diameter; flower about 4 cm. in diameter. Low elev. in Tex., perhaps at Laredo; definitely in N.L.

8. *Coryphantha cornifera* (DC.) Britt. & Rose. Stems solitary or sometimes several, cylindroid (the younger globose), 7.5-10.25 cm. long, 4.4-6 cm. in diameter; tubercles protruding 9-12 mm.; central spines gray or sometimes reddish, 1 to 4 per areole (0 in juvenile plants), the lower (principal) one porrect, 9-17 mm. long, 1-1.5 mm. in diameter, acicular; radial spines 16 to 26 per areole, spreading; flower about 5 cm. in diameter; petaloid perianth parts yellow; fruit green, fleshy; seed brown, smooth and shining, minutely punctate, 1.2 mm. long, 2 mm. broad.

Var. *Echinus* (Engelm.) L. Benson. Central spines 3 or 4, the lower one somewhat larger, straight or curving, 12-17 or 22 mm. long, basally 1-1.5 mm. in diameter; radial spines 16 to 26. Limestone in the desert at 660-900 or 1,400 m., from El Paso Co. to Howard, Coke and Val Verde cos.; also Chih. and Coah.

9. *Coryphantha strobiliformis* (Poselger) Orcutt. Stems solitary or forming clumps, cylindroid, 5-12.5 or 20 cm. long, 2.5-5 cm. in diameter; tubercles cylindroid, protruding 1 cm., becoming spineless, hard and persistent on the lower part of the stem; central spines straw-yellow, usually tipped with pink or pale-red, the principal one central in the areole, surrounded by 5 to 7 smaller ones, straight, up to 12-15 mm. long, 0.3 mm. in diameter, acicular; radial spines pale-straw-color or white or pale-gray, 20 to 30 per areole; flower 2-3 cm. in diameter; petaloid perianth parts pink; fruits red or sometimes

some of them green, fleshy; seed brown, punctate, 0.8 mm. long, 1 mm. broad; hilum very small, appearing "sublateral." *Escobaria tuberculosa* (Engelm.) Britt. & Rose.

Var. *strobiliformis*. Stem 5-12.5 cm. long, 2.5-5 cm. in diameter; the most central spine longest, surrounded by 5 to 7 smaller centrals, up to 12-15 mm. long, to 0.3 mm. in diameter. Limestone in deserts and grasslands at 750-1,550 m. from El Paso Co. to Pecos and Terrell cos.; also Ariz., N.M. and Chih.

Var. *durispina* (Quehl) L. Benson. Stem 15-20 cm. long, about 5 cm. in diameter; the most central one or two spines surrounded by 4 to 6 centrals, some smaller, up to 15-19 mm. long, some about 0.6 mm. in diameter. In the Big Bend; "Mex."

10. *Coryphantha Sneedii* (Britt. & Rose) Berger. Stems much-branched, forming clumps, cylindroid, 25-75 mm. long, 1-2.5 cm. in diameter; tubercles protruding 3 mm., persistent and hard after fall of the spines; spines obliterating the stem; central spines white, tipped with pink or lavender, about 6 to 9 per areole, the strictly central one short, straight, the longer ones 4.5-6 mm. long, to 0.3 mm. in diameter, acicular; radial spines white, 25 to 35 per areole, those on the upper side of the areole 4.5-6 mm. long, those on the lower 3 mm. long; flower 12-19 mm. in diameter; petaloid perianth parts white or at least the midribs pink or rose or magenta or partly brownish; fruit green or tinged with brown or red; seed reddish-brown, strongly reticulate, 0.75 mm. long, 1.25 mm. broad; hilum appearing "sub-basal." Limestone ledges in the desert and grassland at 1,300 or 1,500-1,650 m., N.M. and Tex. in the Franklin Mts.

11. *Coryphantha dasyacantha* (Engelm.) Orcutt. Stems solitary (so far as known), the older ones elongate-cylindroid, 75-175 mm. long, 5-7.5 cm. in diameter; tubercles persisting on the lower part of the stem and becoming hard after the fall of the spines, protruding 4.5-12 mm.; central spines varying upward from the light-colored bases through pink, then red to black, 1 to 4 or 5 per areole, 1 usually porrect to directed downward, up to 9-12 mm. long, 0.25 or to 0.5 mm. in diameter, acicular; radial spines white or straw-color, 16 to 28 per areole; flower 2-2.5 cm. in diameter; petaloid perianth parts pink; fruit red, fleshy; seed dark-brown to "almost black," 1 mm. long, 0.7 mm. broad; hilum large, obliquely basal. *Escobaria dasyacantha* (Engelm.) Britt. & Rose.

Var. *dasyacantha*. Spines obscuring the stem; radial spines white, about 24 to 28 per areole, up to 7.5-10.5 mm. long. Igneous rocks and probably limestone mostly in woodland and grassland at 800-1,700 m. from El Paso to the Big Bend; endemic.

Var. *varicolor* (Tiegel) L. Benson. Spines not dense, the green of the stems conspicuous; radial spines straw-color or some small ones white, 16 to 18 per areole, to 6 mm. long. Igneous rocks, limestone or novaculite in grassland at 500-1,400 m., in Presidio, Jeff Davis and Brewster cos.; endemic.

12. *Coryphantha Robertii* Berger. Stems branching and forming clumps, cylindroid to ovoid-cylindroid, ultimately 3.8-5 or 12.5 cm. long, 2-2.5 cm. in diameter; tubercles protruding 6-9 mm.; spines obscuring the stem; central spines pale-yellow with dark either red, brown or black tips, 5 to 8 per areole, mostly turning upward, straight, to 12 mm. long, 0.2 mm. in diameter, acicular; radial spines white, averaging 20 to 30 per areole; flower as a whole with a bronze-pink appearance, 2-2.5 cm. in diameter; petaloid perianth parts lavender to pale-purple; fruit red, fleshy; seed black or brown, punctate, 1-1.25 mm. long, 1 mm. broad; hilum clearly basal. Limestone in the desert or grassland at 300 m., from Val Verde Co. to Hidalgo Co.; also Coah. to Tam.

13. *Coryphantha Duncanii* (Hester) L. Benson. Stems solitary or rarely 2 or 3, broadly turbinate or subglobose to obconical, 2.5-6 cm. long and of equal diameter; tubercles protruding 4.5-6 mm.; spines completely obscuring the stem, in several series, the innermost larger but the distinction of central and radial spines not clear, white or with short dark-brown tips, 30 to 75 per areole, straight or bent or curved or twisted through crowding, slender, fragile, up to 9-12 or 22 mm. long, 0.1-0.2 mm. in diameter, acicular; flower 10.5-12 cm. in diameter; petaloid perianth parts pink; fruit red; seed black, shiny, the surface pitted, 1-1.2 mm. long, 0.8 mm. broad; hilum obviously basal. Limestone of deserts at 1,000-1,650 m., N.M. and Tex. in Brewster Co.

14. *Coryphantha missouriensis* (Sweet) Britt. & Rose. Stems solitary or branching and forming clumps, hemispheroid to depressed-globose, 2.5-5 cm. long, 3.8-5 or 10 cm. in diameter; tubercles elongate, protruding 12-15 mm.; areoles circular; spines *pubescent*; central spine(s) commonly none but sometimes 1 or rarely 2 per areole, not conspicuously

differentiated; radial spines 8 to 20 per areole, spreading, straight, to 1-2 cm. long, slender, 0.3 mm. in diameter, acicular; flower 25-56 mm. in diameter; fruit red, fleshy; seed black, obviously punctate, 1-2.5 mm. long, 1.5-2 mm. broad; hilum clearly basal, slightly oblique. *Neobesseya missouriensis* (Sweet) Britt. & Rose.

Var. *caespitosa* (Engelm.) L. Benson. Radial spines usually 12 to 15; flower 5-6.2 cm. in diameter; sepaloïd perianth parts fimbriate; petaloïd perianth parts acuminate-attenuate; fruit globular to ellipsoid, 1.5-2 cm. long; seed 2-2.5 mm. long. *Neobesseya similis* (Engelm.) Britt. & Rose. Kan. to Bexar Co., Tex. and n.w. La.

Var. *robustior* (Engelm.) L. Benson. Radial spines usually 12 to 15; flower 4.4-5 cm. in diameter; sepaloïd perianth parts *not* fimbriate; petaloïd perianth parts abruptly long-acuminate; fruit globose, about 1 cm. in diameter; seed not available. *Neobesseya Wissmannii* (Hildemann) Britt. & Rose. Tex. Panhandle and just s. in the Plains Country; endemic.

13. ARIOCARPUS SCHEIDW.

Stem unbranched, turbinate, above ground flattened or depressed-globose, 6-12.5 cm. in diameter; tubercles separate, often flattened and imbricated like the petals of a cultivated rose, in the local species sculptured, cartilaginous, tending to be triangular or prismatic; roots large and fusiform; leaves not discernible; areole none or vestigial in the adult plant; spines present only in very young plants; flower on the new growth near the apex of the stem at the base of the obscure hair-covered upper side of a tubercle and distant from the vestige (if any) of the spine-bearing part of the areole and (in the species in the United States) connected with it by an isthmus; flower 2-5 cm. in diameter, rotate-campanulate; floral tube above the ovary obconical, white or magenta; fruit greenish, red or reddish-purple but turning brown, fleshy at maturity, the surface bare; seed black, shiny, slightly longer than broad (hilum to opposite side); hilum obviously basal; cotyledons accumbent, not foliaceous.

Six species from Texas to Querétaro.

1. *Ariocarpus fissuratus* (Engelm.) K. Schum. **LIVING ROCK.** Stem solitary, gray-green, inconspicuous, broadly turbinate, only the flattened or somewhat convex top protruding above ground, 3.8-5 cm. long, to 1 dm. in diameter; areoles densely woolly; flower to 3.4 or 4 cm. in diameter; petaloïd perianth parts pale-magenta; fruit white to greenish, fleshy but drying at maturity and becoming brown; seed 0.8 mm. long, 0.6 mm. broad. Limestone in the desert at 500-3,300 m., from Presidio Co. to the Pecos River; also adj. Chih. and Coah.

FAM. 132. LYTHRACEAE ST.-HIL.

LOOSESTRIFE FAMILY

Herbs, shrubs or trees; leaves opposite, whorled or alternate, simple, entire; stipules minute or wanting; flowers perfect, regular or sometimes irregular, solitary or clustered, 4- to 7-parted, the peduncles usually bibracteolate; calyx tubular to campanulate, persistent, 4- to 6-toothed and often with accessory teeth in the sinuses, the toothlike lobes valvate; petals inserted in the throat of the hypanthium between the lobes or rarely absent; stamens 4 to many, inserted on the hypanthium, when as many as the petals then opposite the sepals; style simple or wanting, the stigma capitate; fruit capsular, dry, 1- to several-celled.

About 550 species in 25 genera, mostly in the tropics.

1. Shrubs or small trees (2)

1. Herbs or only partially suffrutescent (4)

2(1). Flowers in terminal panicles; terrestrial shrub or small tree 1. *Lagerstroemia*, p. 1114.

2. Flowers axillary (3)

3(2). Flowers in cymes in leaf axils; aquatic shrub 2. *Decodon*, p. 1114.

3. Flower solitary in leaf axils; not strictly aquatic 3. *Heimia*, p. 1114.

- 4(1). Flowers irregular; calyx gibbous or spurred at base; petals unequal
8. *Cuphea*, p. 1117.
4. Flowers regular or nearly so, symmetrical (5)
- 5(4). Hypanthium elongated, cylindrical or tubular4. *Lythrum*, p. 1115.
5. Hypanthium campanulate or turbinate, becoming hemispheric or globose (6)
- 6(5). Flowers two or more in leaf axils; capsules bursting irregularly
5. *Ammannia*, p. 1116.
6. Flowers solitary in leaf axils; capsules indehiscent or regularly dehiscent (7)
- 7(6). Petals wanting; capsules indehiscent; submersed aquatic plants
6. *Pepelis*, p. 1117.
7. Petals present; capsules dehiscent; terrestrial or marsh plants (8)
- 8(7). Flowers sessile; capsules septicidally dehiscent7. *Rotala*, p. 1117.
8. Flowers pedunculate; capsules variously dehiscent3. *Heimia*, p. 1114.

1. LAGERSTROEMIA L.

CRAPE-MYRTLE

About 50 species in Asia and Australasia.

1. *Lagerstroemia indica* L. CRAPE-MYRTLE, CRESPO'N. Deciduous shrub or small tree, to about 7 m. high, the branchlets 4-angled, the trunk to 17 cm. in diameter, the gray bark smooth; leaves sessile or nearly so, alternate, suborbicular to oblong-elliptic or obovate, entire, to 7 cm. long, rounded to broadly cuneate at base, emarginate to rounded or sometimes short-acuminate at apex, glabrous or hirtellous along the midrib beneath; stipules conical, deciduous; flowers in terminal panicles to 2 dm. long, pedicellate, 4- to 7-parted, perfect, regular; pedicels bracted; calyx campanulate, smooth, 7-10 mm. long; petals usually 6, to 2 cm. long, white to pink or purple, with slender claws, the blades orbicular-cordate and crisped-erose; stamens 36 to 42, with long filaments; capsule 6-celled, ellipsoid-globose, loculicidal, about 1 cm. long; seeds winged at top.

A handsome Old World shrub that is widely cultivated for its highly ornamental flowers; occurring as an escape in old fields and about abandoned homesteads in south Texas.

2. DECODON J. F. GMEL.

A monotypic genus.

1. *Decodon verticillatus* (L.) Ell. WATER-WILLOW, SWAMP-LOOSESTRIFE. Perennial herb or suffrutescent, smooth or downy; stems 4- to 6-sided, to 25 dm. long, recurved-arching and rooting at tips, the bark of submersed parts spongy-thickened; leaves shortly petioled, opposite or whorled, elliptic-lanceolate to lanceolate, acute to subacuminate, to about 1 dm. long and 4 cm. wide, the upper ones with clustered pedicelled flowers in their axils; flowers trimorphous; calyx with 5 to 7 erect teeth and as many longer and spreading terete hornlike processes at the sinuses; petals 5, cuneate-lanceolate, magenta, crinkly, about 12 mm. long; stamens 10, of 2 lengths, exerted; style filiform, about 14 mm. long; capsule globose, 3- to 5-celled, loculicidal, black, 3-5 mm. in diameter. In swamps, shallow pools, in and on margin of ponds and lakes in e. Tex., July-Oct.; from Fla. to Tex., n. to N.E., N.Y., s. Ont. and s. Ill.

The characteristic of the stems rooting at their tips enables the plant to spread rapidly.

3. HEIMIA LINK & OTTO

Slender deciduous herbs or shrubs; leaves opposite or with some alternate, exstipulate; flowers pedunculate, solitary in the axils of the leaves; calyx campanulate, with hornlike spreading processes between the lobes; petals 5 to 7; stamens 10 to 18; style slender, the stigma capitate; capsule 4-celled.

Three species from Texas south to Argentina.

- 1. Leaves tapering to a sessile or short-petioled base; peduncle stout, about 2 mm. long, the bracts elliptic-oblancheolate and about 4 mm. long and 2 mm. wide; petals yellow 1. *H. salicifolia*.
- 1. Leaves auricled at base; peduncle filiform, more than 1 cm. long, the bracts ovate and about 2 mm. long and 1 mm. wide; petals pink to purple 2. *H. longipes*.

1. *Heimia salicifolia* (H.B.K.) Link & Otto. HACHINAL. Shrub to 3 m. high, usually much smaller, glabrous throughout; leaves mostly opposite, sessile to short-petioled, linear-oblancheolate to linear-lanceolate or lanceolate, to about 5 cm. long and 1 cm. wide, obtuse to acute at apex; flowers solitary and short-pedunculate in the axils, inodorous; calyx campanulate, 5-9 mm. long, with triangular acuminate lobes that become closely connivent over the capsule; petals 5 to 7, orange-yellow, oval, 12-17 mm. long, fugacious; capsule about 4 mm. in diameter, loculicidal. *Nesaca salicifolia* H.B.K. Along resacas, streams or in wet soil in brushlands in the Rio Grande Plains of s. Tex., Mar.-June; from Tex., s. through Mex. to C.A. and S.A.; also Jam.

2. *Heimia longipes* (Gray) Cory. Subshrubby to somewhat herbaceous plants with sprawling and trailing much-branched slender stems to 9 dm. or more long, glabrous throughout; leaves subsessile, linear, acute at apex, auriculate at base, with prominently revolute margins, to 5 cm. long and 4 mm. wide; peduncles filiform, elongated, often about as long as the leaves, bibracteolate below the flowers; calyx 5-7 mm. long, with short 2-grooved triangular lobes; petals pink to purple, obovate, 6-7 mm. long; style filiform, much-exserted; capsule about 4 mm. in diameter, opening by a little lid and then splitting septifragally. *Nesaea longipes* Gray. On seepage rocks and about springs in the Edwards Plateau and the Trans-Pecos, May-July; apparently endemic.

4. LYTHRUM L. LOOSESTRIFE

Herbs or shrubs with 4-angled stems; leaves opposite, alternate or sometimes whorled, entire; flowers usually solitary in the axils, often dimorphous, with a short bibracteolate peduncle; calyx tube cylindric, 8- to 12-ribbed, 4- to 7-toothed, with an equal number of appendages in the sinuses; petals 4 to 6, attached to the rim of the calyx tube, rarely wanting; stamens 4 to 12, inserted rather low on the calyx tube; style filiform; capsules cylindrical, included in the calyx tube, membranous, 2-celled, usually bursting irregularly; seeds numerous.

About 35 species of wide geographical distribution.

- 1. Stem leaves mostly widest at or above the middle, tapering or abruptly contracted into a subpetiolar base (2)
- 1. Stem leaves mostly widest below the middle, somewhat rounded to subauriculate at the usually sessile to clasping base (3)
- 2(1). Stem leaves broadly elliptic to elliptic-obovate, rounded to subobtuse at apex; endemic in Edwards Plateau 1. *L. ovalifolium*.
- 2. Stem leaves typically narrowly elliptic, acute to acuminate at apex; widespread in eastern third of Texas 2. *L. lanceolatum*.
- 3(1). Leaves of inflorescence typically linear-lanceolate; appendages of calyx tube subulate and erect, much longer than the teeth; distribution Panhandle and north-central Texas 3. *L. dacotanum*.
- 3. Leaves of inflorescence typically linear; appendages of calyx tube fleshy-mammillate and curved outward, about as long as the teeth; distribution south-central and west Texas 4. *L. californicum*.

1. *Lythrum ovalifolium* Koehne. Perennial herb to 35 cm. high, the stem much-branched from near base; stem leaves broadly elliptic to elliptic-obovate, rounded to obtuse at apex, to 25 mm. long and 8 mm. wide, abruptly contracted at base, membranous; leaves of inflorescence similar to stem leaves but much smaller; calyx tube 5-6 mm. long; petals obovate, lavender, 3-4.5 mm. long, 1.5-2 mm. wide. Rare along and in water of rivers and streams in the e. Edwards Plateau, Apr.-June; endemic.

2. *Lythrum lanceolatum* Ell. Plant to 1 m. or more high, the stem usually much-branched (especially above), often in large clumps; stem leaves elliptic to elliptic-lanceolate, to 55 mm. long and 1 cm. wide, acute to acuminate at apex, tapering to a cuneate base with straight margins; leaves of inflorescence similar to stem leaves but much smaller; calyx tube about 5 mm. long, the slenderly subulate appendages much longer than the teeth; petals obovate, purple or cerise-red to lavender-blue, 3-6 mm. long; ovary with a thick ring at base. Rather frequent in meadows, prairies, ditches and depressions in the e. third of Tex., rare elsewhere in Tex., Apr.-Oct.; from Tex. and Okla., e. to Fla., Va. and Tenn.

3. *Lythrum dacotanum* Nieuw. Perennial from a woody rootstock, to about 1 m. high, the stems mostly much-branched, rarely simple; stem leaves elliptic to elliptic-lanceolate or linear-lanceolate, rounded to subauriculate at base, obtuse to acute at apex, to 35 mm. long and 7 mm. wide; leaves of inflorescence similar to the stem leaves but much smaller; calyx tube 5-6 mm. long; petals purple, obovate, 5-7 mm. long. *L. alatum* of Tex. reports (probably). Mostly in prairies and meadows of Panhandle and n.-cen. Tex., May-July; from Tex. and Ark., e. to Ga., Tenn. and Va., w. to Colo. and Wyo., n. to Ont.

4. *Lythrum californicum* T.&G. HERBA DEL CÁNCER. Perennial with creeping woody rootstock, to 15 dm. high, usually much smaller, pale-green and glabrous; stems mostly erect, paniculately and divaricately branched above; stem leaves alternate, firm, narrowly linear to linear-oblong or the lower leaves sometimes lanceolate, acute at apex, more or less rounded to somewhat auriculate at the sessile base, to about 3 cm. long and 5 mm. wide; leaves of inflorescence linear, obtuse to acute, much smaller than the stem leaves; calyx tube cylindric, 5-7 mm. long, the subulate teeth sharply acute; petals obovate, bright-purple, 4-6 mm. long, 2-4.5 mm. wide; capsule oblong-clavate, the linear-lanceolate seeds about 1 mm. long. *L. alatum* Pursh var. *breviflorum* (Gray) Wats., *L. linearifolium* (Gray) Small, *L. parvulum* Nieuw. In moist ground or water along streams, about ponds and springs, in depressions, and salt flats mainly in s.-cen. and w. Tex., Mar.-Nov.; from Tex., n. to Kan. and w. to Calif. and n. Mex.

5. AMMANNIA L.

Mostly low and inconspicuous glabrous annual herbs, the stems mostly 4-angled; leaves opposite, sessile, entire, narrow and often elongated; flowers small, usually in 3- to many-flowered axillary cymes, usually 4-merous; calyx globose or campanulate, 4-angled, 4-toothed, usually with a little horn-shaped appendage in each sinus; petals 4, small, deciduous, sometimes wanting; stamens 4 to 8, inserted on the calyx tube; style somewhat persistent; capsule 2- to 4-celled, bursting irregularly; seeds numerous, angled and minutely pitted.

About 30 species widespread in tropical and warm temperate regions.

- 1. Cymes decidedly pedunculate; mature capsule surpassing the calyx 1. *A. auriculata*.
- 1. Cymes sessile or essentially so; mature capsule equal to or shorter than the calyx (2)
- 2(1). Style 1.5-3 mm. long; leaves linear to narrowly oblong, clasping stem at the auriculate base 2. *A. coccinea*.
- 2. Style about 0.5 mm. long; leaves linear-oblong to oblanceolate, the lower ones cuneate at base, the upper ones truncate to cordate-auriculate at base 3. *A. teres*.

1. *Ammannia auriculata* Willd. Plant erect or with a few short ascending branches, to about 8 dm. high, usually much smaller; leaves linear-lanceolate to linear, long-attenuate, to 5 cm. long and 7 mm. wide, all but the very lowest auriculate-cordate at base; cymes loosely 3- or more-flowered on peduncles to 5 mm. or more long or with solitary flowers on pedicels to about 3 mm. long; calyx 1.5-2 mm. long, with prominent triangular teeth, 8-nerved, in fruit becoming subglobose and 2-3 mm. in diameter; petals minute, purple to white, soon dropping; style filiform, 1.5-3 mm. long; capsule surpassing the calyx; seeds reddish-brown. In swamps, ditches and about pond margins throughout much of cen. Tex., May-July; from Miss. to N.M. and Mex., n. to Ind. and S.D.

2. *Ammannia coccinea* Rottb. TOOTH-CUP. Plants rather stout, ascending or depressed-

spreading, to about 5 dm. high, the stem branched below and spongy when growing in water; leaves linear-oblong to linear-lanceolate, to 1 dm. long and 15 mm. wide, mostly much smaller, cordate-auriculate and clasping stem at base, acute to acuminate at apex; cymes closely 2- to 5-flowered, essentially sessile; calyx 2.5-5 mm. long, in fruit 3-5 mm. in diameter; petals pink to purple, 1-2 mm. long, fugacious; style persistent, 1.5-3 mm. long; capsule about 4 mm. long. In mud of ditches, ponds, lakes and streams in e., cen. and extreme s. Tex., Apr.-Nov.; from Fla. to Tex. and Mex., n. to O., Ill., Minn., Neb., Mont. and Wash.

3. *Ammannia teres* Raf. Plant erect, the stout stems simple or with few erect branches near the base, to about 6 dm. high, usually much smaller, fleshy; leaves oblong to oblanceolate, obtuse to subacute at apex, tapering at base or rarely subauriculate, the longer leaves to 6 cm. long; flowers several in the axils, sessile; calyx teeth very short and broad; petals pink, about 1 mm. long, fugacious; style thick, about 0.5 mm. long; fruiting calyx about 5 mm. in diameter; seeds whitish-brown. Swamps and tidal marshes in s.e. Tex., summer; from Fla. to Tex., n. to N.J.

6. PEPLIS L.

A monotypic genus.

1. *Peplis diandra* Nutt. WATER-PURSLANE. Aquatic or sometimes terrestrial herb, rooting in mud, glabrous, with slender simple stems to about 4 dm. long; leaves opposite, those of submersed plants elongated, linear, minutely retuse at the obtusish apex, thin and flaccid, closely sessile by a broad base, to about 3 cm. long and 3 mm. wide, when emersed shorter and contracted at base; flowers small, greenish, solitary and sessile in axils of leaves; calyx without appendages, 2-3 mm. long, with 4 broad triangular pinkish lobes; petals none; stamens 4; style abbreviated; capsule globose, 2-celled, indehiscent, about 2 mm. in diameter. *Didiplis diandra* (Nutt.) Wood. In shallow water and on margin of water of ponds and lakes in e. Tex., Mar.-June; from Fla. to Tex., n. to Va., O., Ind. and Wisc.

7. ROTALA L.

About 50 species, widespread mostly in tropical or subtropical regions.

1. *Rotala ramosior* (L.) Koehne. ТООТН-СУР. Small annual herb, low and sprawling to erect and spreading, with simple or diffusely branched 4-angled stems, glabrous, to 45 cm. high, usually much smaller; leaves opposite, subsessile to somewhat petioled, linear-oblong to elliptic or oblanceolate, obtuse, to about 45 mm. long and 1 cm. wide; flowers regular or nearly so, small, solitary in leaf axils, 4-merous, bibracteolate; calyx with appendages shorter to longer than the teeth, the tube campanulate to globose; petals 4, attached to rim of calyx tube, white or pink; stamens 4, attached low on calyx tube; capsule globose, 4-celled, enclosed in the membranous calyx, the valves minutely transverse-striate, to 5 mm. long and 4.5 mm. broad, the somewhat persistent style about 0.5 mm. long; bractlets linear-lanceolate to subulate, to 4 mm. long. In sandy or muddy soil in water or on the edge of ponds, lakes, tanks and in depressions in the e. half of Tex., May-Oct.; from Fla. to Tex., n. to N.E., N.Y. and the Lake States; also Wash. and Ore.

Most of our material is referable to var. *interior* Fern. & Griseb. This is a more robust and upright plant than var. *ramosior*. The larger leaves are usually subsessile and are 5-10 mm. wide, the capsules are 3.5-5 mm. long and 3.2-4.5 mm. broad, and the linear-lanceolate bractlets are 1.6-4 mm. long. These organs in var. *ramosior* have smaller measurements.

8. CUPHEA P. BR.*

Herbs or woody plants, mostly clammy-pubescent; leaves entire; flowers solitary in axils or in terminal spikes or racemes; calyx tubular, 12-ribbed, gibbous or spurred at

* See Appendix.

base on upper side, the 6 lobes with small teeth in the sinuses; petals 6, unequal; ovary with a curved gland at the base next to the calyx spur, 1- or 2-celled; style slender, the stigma 2-lobed; stamens 6 to 14, adnate to near the top of the hypanthium; embryo with orbicular cotyledons; capsule ovoid or ellipsoid, few-seeded, soon ruptured on one side.

About 250 species, primarily in the American tropics.

1. Mature calyx 5-7 mm. long, the limb subequally 5-lobed 1. *C. carthagensis*.
 1. Mature calyx 8-12 mm. long, the limb noticeably bilabiate 2. *C. viscosissima*.

1. *Cuphea carthagensis* (Jacq.) Macbr. Plant annual, 2-9 dm. high, the stem and branches with scattered bristly hairs; leaves short-petiolate, elliptic to oval or sometimes obovate, 2-6 cm. long, rugose (especially with age); hypanthium and calyx 5-7 mm. long, usually with few bristles; calyx lobes minute, broadly deltoid; petals pink or bluish, elliptic or nearly so, 1.5-2 mm. long; capsule 4-5 mm. long. On edge of low wet woods, rare in s.e. Tex. (Hardin Co.), July-Sept.; from S.A., n. through C.A. and Mex. to Tex. and N.C.

2. *Cuphea viscosissima* Jacq. BLUE WAXWEED. Plant annual, viscid-hairy, 1-7 dm. high; leaves with petioles to about 15 mm. long; blade lanceolate to ovate-lanceolate, 1-3.5 cm. long; hypanthium and calyx 8-12 mm. long; calyx limb prominently bilabiate, the upper lip much broader than long; petals ovate, short-clawed, rose-purple, the upper ones 4.5-5.5 mm. long; capsule 6-8 mm. long; seeds flat. *C. petiolata* (L.) Koehne. Fields, roadsides and edge of streams and lakes, one Tex. record without definite locality; from Ga. to La., Tex. and Okla., n. to Kan., Ia. and N.E.; July-Oct.

A sheet of the Arizona-Mexican *Cuphea Wrightii* Gray in the Gray Herbarium is labeled "Texas, Hale," but its accuracy is questionable. This species is distinguished from the allied *C. viscosissima* by its greatly reduced petals, more coarse and sparse bristly hairs, and lack of puberulence, especially on lower surface of leaves.

FAM. 133. MELASTOMATACEAE JUSS. MELASTOMA FAMILY

Trees, shrubs, herbs or rarely vines with simple opposite 3- to 7- or rarely 1-nerved leaves and commonly showy cymose flowers; flowers perfect, regular, mostly 4- or 5-merous; hypanthium variously shaped; sepals valvate and petals convolute in bud; stamens twice as many as petals, often dimorphic; anthers opening by pores at the apex, commonly with an appendage; ovary superior; fruit a capsule; seeds usually numerous, variously shaped and adorned.

A large tropical family of about 240 genera and 3,000 species.

1. RHEXIA L.¹³⁸

MEADOW BEAUTY. DEER-GRASS

Erect herbaceous or suffrutescent perennials, with one to several simple or branched stems arising from the bases of previous shoots, from a woody crown, from horizontal-spreading roots or from tuberous roots, essentially glabrous to densely glandular-pubescent throughout; stems becoming woody or spongy below, subterete about the middle with 4 well-defined faces (sides) whose edges are inconspicuously to prominently winged; faces of stem flat to convex and essentially equal or with one pair of opposing faces flat to concave and much narrower than the other pair of convex or rounded faces; leaves opposite, sessile to petiolate, suborbicular-ovate to linear-lanceolate or narrowly elliptic-linear, with one to several palmate veins and with the margins ciliate to serrulate or serrate; flowers usually showy, solitary or borne in cymes; petals 4, distinct, oblique, cuneate to suborbicular, fugacious, mostly rose-color to purple, sometimes white or yellow; hypanthium more or less urceolate, glabrous to variously glandular-pubescent,

¹³⁸ Adapted from C. W. James in Brittonia 8:201-230. 1956. See Appendix.

the lower portion somewhat ventricose and enclosing all or most of the capsule, constricted or narrowed above to usually form a neck, sometimes expanded above the neck; calyx lobes 4, erect to spreading or strongly recurved, deltoid to lanceolate, obtuse to acuminate or rarely aristate; stamens 8, isomorphic; anthers 1-celled at anthesis, basifixed, commonly with an appendage at base, yellow, smooth to papillose, more or less lanceolate in outline, straight or curved to sigmoid, dehiscing by a pore; ovary 4-celled; fruit a capsule; seeds strongly curved to cochleate, variously adorned.

A small genus of about a dozen species that are centered in southeastern United States.

1. Anthers straight, 1-3 mm. long, the pore nearly equaling the diameter of the anther tip; neck of the hypanthium conspicuously constricted at the base, abruptly expanded above (2)

1. Anthers curved, 4 mm. long or more, the pore only about one third the diameter of the anther tip; neck of the hypanthium not constricted at the base, gradually (if at all) expanded above (3)

2(1). Petals rose-color; stem glabrous; leaves ovate to oval or elliptic, less than 3 times as long as wide1. *R. petiolata*.

2. Petals yellow; stem hirsute; leaves typically linear-elliptic, more than 3 times as long as wide2. *R. lutea*.

3(1). One pair of opposing faces of the stem flat to concave and much narrower than the other pair of convex or rounded faces; stem neither conspicuously winged nor spongy-thickened below; leaves petiolate; petals or mature hypanthium (or both) glabrous; flowers white, rose or purple (4)

3. Faces of the stem flat to convex and essentially equal; stem with conspicuous wings (to about 2 mm. wide) and spongy-thickened below or (if neither) then with hairs on the abaxial surface of the petals and on the mature hypanthium; leaves sessile or nearly so; flowers rose to purple (5)

4(3). Mature hypanthium mostly 9-11 mm. long, with scattered hairs; leaves mostly 8-15 mm. wide, rarely falcate; flowers whitish-rose to rose3. *R. mariana* var. *mariana*.

4. Mature hypanthium mostly 6-9 mm. long, usually glabrous; leaves mostly 2-8 mm. wide, frequently falcate; flowers pure-white to rose, occasionally purple3. *R. mariana* var. *exalbida*.

5(3). Roots tuberous; stem with conspicuous wings and often spongy-thickened below; leaves frequently broadest near the base4. *R. virginica*.

5. Roots nontuberous; stem lacking conspicuous wings and rarely spongy-thickened below; leaves frequently broadest near the middle ..5. *R. interior*.

1. *Rhexia petiolata* Walt. Plant to 6 dm. tall; leaves to 25 mm. long and 15 mm. wide, 3-nerved, somewhat petiolate; hypanthium glabrous at maturity, 5-9 mm. long; calyx lobes to 4 mm. long and 3 mm. wide, with serrate to ciliate margins; petals rose-color, elliptic, to 2 cm. long. *R. ciliosa* Michx. In peaty or sandy soils of moist pinelands of s.e. Tex., July-Sept.; along coast from s.e. Va. to cen. Fla., w. to Tex.

The typically oval leaves and sessile flowers are characteristics of this species.

2. *Rhexia lutea* Walt. Plant to 5 dm. tall, the stems usually much-branched; leaves to 25 mm. long and 8 mm. wide, 3-nerved, essentially sessile; hypanthium at maturity glabrous or with few scattered glandular hairs, 5-8 mm. long; calyx lobes to 3 mm. long and wide, with glandular hairs on margins; petals yellow, elliptic, to 13 mm. long. In moist savannahs and open pinelands of s.e. Tex., May-June; along coast from e. N.C. to n. Fla., w. to Tex.

The yellow petals are distinctive.

3. *Rhexia mariana* L. var. *mariana*. Plant to 7 dm. tall, the stem with axillary branches; leaves petiolate, elliptic to lanceolate, to 6 cm. long, the margins serrate, ciliate; calyx lobes triangular to lanceolate, to 3 mm. long; petals obovate, to about 18 mm. long. In ditches, wet meadows, seepage bogs, savannahs, edge of thickets and similar places that are wet or moist, throughout e. Tex., May-Sept.; from Mass. s. to Ga., w. to Tex. and Okla., n.w. to Mo., Ill. and Ind.

The leaves narrowed to petioles readily distinguish this species from *R. virginica*.

Var. *exalbida* Michx. Differing from var. *mariana* in being smaller in all its parts. In similar habitats to those of var. *mariana* but more southern in distribution; from e. N.C. to s. Fla., w. to e. Tex.

4. *Rhexia virginica* L. COMMON MEADOW BEAUTY. Plant to 1 m. tall; leaves ovate to ovate-lanceolate or elliptic, to 1 dm. long and 35 mm. wide, the margins serrate-ciliate, sessile or with petioles to 5 mm. long; hypanthium to 1 cm. long, glandular-hispid at maturity; calyx lobes triangular to lanceolate, to 2.5 mm. long; petals dark-rose-color to purple, obovate, to 17 mm. long. On open seepage slopes and in bogs of e.-cen. Tex., June-Oct.; throughout e. U.S., excluding Fla., n. to N.S. and Ont., w. to Kan. and Tex.

5. *Rhexia interior* Penn. This is not an altogether clear species. It is supposed to differ from the nearly allied *R. virginica* in its nontuberous roots and in its smaller (0.5-0.7 mm. long), less papillose seeds. It is also centered in the interior prairies of Mo. and Kan., extending e. to Ind., Ky. and Tenn. and s. to La. and Tex.

FAM. 134. ONAGRACEAE JUSS.¹³⁹

EVENING PRIMROSE FAMILY

Herbs, sometimes woody near the base; leaves alternate or opposite, simple, entire, toothed or pinnatifid; stipules minute or lacking; flowers actinomorphic or slightly zygomorphic, perfect, 4- or 5- (rarely 6-) merous, borne in the axils of usually reduced foliage leaves; hypanthium prolonged beyond the ovary or not; sepals free; corolla white to rose-purple or yellow, the petals free; stamens as many as the sepals and opposite them or twice as many; ovary 4- or 5-locular; fruit a loculicidally dehiscent, pericidal capsule or nutlike indehiscent structure.

About 650 species in 19 genera, world-wide but largely extratropical; best developed in subarid western North America.

- 1. Sepals persistent in fruit; hypanthium not prolonged beyond the ovary 6. *Ludwigia*, p. 1132.
- 1. Sepals deciduous in fruit; hypanthium obviously prolonged beyond the ovary (2)
- 2(1). Stigma deeply 4-lobed (3)
- 2. Stigma entire (6)
- 3(2). Fruit a dehiscent many-seeded capsule; flowers actinomorphic 4. *Oenothera*, p. 1126.
- 3. Fruit indehiscent, hard; flowers actinomorphic or zygomorphic (4)
- 4(3). Flowers borne in axils of upper leaves, these not much reduced, or the plants acaulescent 4. *Oenothera*, p. 1126.
- 4. Flowers borne in essentially naked inflorescences with leafless branches, the plants not acaulescent (5)
- 5(4). Hypanthium filiform; filaments unappendaged; leaves gradually reduced in the inflorescence 5. *Stenosiphon*, p. 1132.
- 5. Hypanthium funnellform, each filament with a small scale at the base (except in *G. parviflora*); leaves abruptly reduced in the inflorescence 3. *Gaura*, p. 1123.
- 6(2). Seeds with a tuft of hairs (coma) at one end; stigma clavate 7. *Epilobium*, p. 1135.
- 6. Seeds lacking a coma; stigma capitate or peltate (7)
- 7(6). Stigma more or less peltate; flowers yellow 2. *Calylophus*, p. 1121.
- 7. Stigma capitate; flowers white, minute 1. *Camissonia*, p. 1121.

¹³⁹ Contributed by Peter H. Raven, whose work was supported by grants from the National Science Foundation. Cf. another treatment by P. A. Munz in C. L. Lundell, *Flora of Texas* III:208-262. 1944. Measurements of the hypanthium apply only to the portion prolonged beyond the ovary.

1. CAMISSONIA LINK

A genus of 61 species, mostly of subarid far western United States and adjacent Canada and Mexico; 1 in temperate South America.

1. *Camissonia chamaenerioides* (Gray) Raven. Erect slender often well-branched annual 8-50 cm. tall, glandular-pubescent with an admixture of strigulose pubescence in and near the inflorescence; leaves alternate, narrowly elliptic, to 8 cm. long and 25 mm. wide, entire to very sparsely denticulate; petioles of basal leaves 1-3.5 cm. long, the upper leaves sessile; stipules absent; flowers actinomorphic, 4-merous, borne in axils of reduced upper leaves, opening near sunset; hypanthium well-developed, 1.6-2.3 mm. long; sepals not persistent in fruit, 1.5-2.5 mm. long, lacking free tips; petals white, 1.8-3 mm. long; stamens 8; stigma capitate; capsule slender, terete, loculicidally dehiscent, 35-55 mm. long; seeds in 1 row in each locule, 0.9-1 mm. long, lacking a coma; $n = 7$. *Oenothera chamaenerioides* Gray. Sandy desert flats and slopes in the Trans-Pecos, Mar.-Apr.; w. to n. Baja Calif. and n.w. Son., s.e. Calif., s. Nev., and s.w. Ut.

2. CALYLOPHUS SPACH^{139A}

Herbs, sometimes woody near the base, with alternate entire to serrate or dentate leaves; stipules absent; flowers actinomorphic, 4-merous, borne in axils of upper leaves, opening either near sunset or near sunrise; hypanthium well-developed; sepals not persistent in fruit; petals yellow; stamens 8; stigma peltate or more or less globose-peltate; fruit a cylindrical loculicidally dehiscent capsule; seeds lacking a coma, in 2 rows in each locule.

A genus of 5 species of Texas and north-central Mexico, ranging into neighboring regions and north in the Great Plains to south-central Canada.

- 1. Sepals with prominent raised or keeled midribs; flower bud sharply 4-angled (2)
- 1. Sepals without prominent raised or keeled midribs; flower bud not sharply 4-angled, but round (4)
- 2(1). Stigma usually exerted at least to end of outer anthers or positioned outside of circle of anthers; petals mostly 9-21 mm. long; pollen usually 85 to 100 percent fertile3. *C. Drummondianus*.
- 2. Stigma not exerted beyond anthers, usually positioned at distal end of inner anthers; petals mostly 6-12 mm. long in Texas plants; pollen 30 to 60 percent fertile (3)
- 3(2). Young stems canescent with slender appressed hairs; Panhandle and north-central Texas4. *C. serrulatus*.
- 3. Young stems with sparse short, thick, incurved hairs; Gulf Coast5. *C. australis*.
- 4(1). Hypanthium funnelliform in upper two-thirds or more, or less than 15 mm. long; flowers opening near sunrise2. *C. Tubicula*.
- 4. Hypanthium funnelliform in upper half or less, 15-55 mm. long; flowers opening in the afternoon or near sunset1. *C. Hartwegii*.

1. *Calylophus Hartwegii* (Benth.) Raven. Bushy perennial from a woody caudex, 5-40 cm. tall; leaves linear to oblong-lanceolate, glabrous to glandular-pubescent to densely gray-canescenscent or villous, entire or subentire to denticulate, 1-5 cm. long, 0.5-10 mm. wide, sessile to short-petiolate; flowers opening in the afternoon or near sunset; hypanthium 15-55 mm. long; sepals 8-18 mm. long, with free tips 0-12 mm. long; petals 1-3 cm. long; $n = 7, 14$; self-incompatible. Wyo. and Neb. to Ariz., Tex., Zac., S.L.P. and Aguasc.

In Texas represented by 6 intergrading subspecies, as follows:

^{139A} Contributed by Howard F. Towner.

1. Ovary (and usually stems and leaf margins) with long spreading hairs; leaves (except lowest) abruptly narrowed to truncate or slightly clasping at the base subsp. *pubescens*.
1. Ovary, stems and leaf margins without long spreading hairs; leaves gradually narrowed at base or extremely narrow throughout (2)
- 2(1). Ovary, stems and leaves glabrous to glabrescent; flowers opening from one hour before to one hour after sunset subsp. *Fendleri*.
2. Ovary (and usually stems and leaves) with some form of pubescence; flowers usually opening 2 to 5 hours before sunset (3)
- 3(2). Plants low, often caespitose, 8-15 cm. high; free sepal tips 0.5-2 mm. long; ovary, stems and leaves grayish with dense strigose pubescence subsp. *lavandulifolius*.
3. Plants usually taller, 10-40 cm. high; free sepal tips 1.5-6.5 mm. long; ovary, stems and leaves rarely all densely grayish-strigose (4)
- 4(3). Ovary and stem with short very glandular hairs; leaves glabrous to glandular-puberulent; northern Trans-Pecos and southern Panhandle subsp. *filifolius*.
4. Ovary, stem and leaves usually with strigose pubescence; southern Trans-Pecos and Rio Grande Valley (5)
- 5(4). Stem leaves (except lowest) usually with crinkled margins, sparsely strigose or occasionally glandular-puberulent, mostly 4.5 to 11 times as long as wide; lower Rio Grande Plains subsp. *Maccartii*.
5. Stem leaves usually lacking crinkled margins, often densely strigose, mostly 9 to 35 times as long as wide; mountains and canyons bordering on the upper Rio Grande subsp. *Hartwegii*.

Subsp. *pubescens* (Gray) Towner & Raven. Gametic chromosome numbers $n = 7, 14$. *Oenothera Greggii* Gray var. *lampasana* (Buckl.) Munz, *Galpinsia camporum* Woot. & Standl. Common in open sandy places and on limestone, n.-cen. Tex. and n. Edwards Plateau, n. and w. to the Panhandle and Trans-Pecos, Apr.-Aug.; s.e. Ariz., s. and e. N.M., w. Okla., s.w. Kan. and s.e. Colo. through w. Tex. to n. Coah.

Subsp. *Fendleri* (Gray) Towner & Raven. Gametic chromosome number $n = 7$. *Oenothera Hartwegii* var. *Fendleri* Gray and var. *Hartwegii* auct., p. p. Uncommon in the e. Panhandle and at high elev. in the Trans-Pecos, Apr.-Aug.; cen. Ariz. to n. N.M., s.w. Kan., e. Okla. and w. Tex.

Subsp. *lavandulifolius* (T.&G.) Towner & Raven. Gametic chromosome number $n = 7$. *Oenothera lavandulifolia* T.&G. var. *glandulosa* Munz. Frequent on open rocky slopes in the High Plains, scattered s. in the South Plains and mts. of the Trans-Pecos, May-Aug.; s. and e. Nev., n. Ariz. to s.e. Wyo., s.w. S.D., w. Kan., w. Okla. and n. and w. Tex.

Subsp. *filifolius* (Eastw.) Towner & Raven. Gametic chromosome number $n = 7$. *Oenothera Hartwegii* var. *filifolia* (Eastw.) Munz. Gypsum and limestone outcrops in n. Trans-Pecos, w.-cen. Tex. and s. Panhandle, Apr.-Aug.; s.-cen. N.M. to w. Tex. and s. Coah.

Subsp. *Maccartii* (Shinners) Towner & Raven. Gametic chromosome numbers $n = 7, 14$. *Oenothera Greggii* var. *Pringlei sensu* Munz, p. p. Common in open sandy places, South Plains, Mar.-Oct.; s. Tex. to n. Tam., n. N.L. and cen. Coah.

Subsp. *Hartwegii*. Gametic chromosome numbers $n = 7, 14$. *Oenothera Greggii* var. *Pringlei sensu* Munz, p. p. Infrequent in mts. and canyons of s. Trans-Pecos, especially along Rio Grande, Mar.-Oct.; w. Tex. and s.e. Ariz. to N.L., S.L.P. and Aguasc.

2. *Calylophus Tubicula* (Gray) Raven. Bushy perennial from a woody caudex, 1-3 dm. tall; leaves narrowly lanceolate to lanceolate, minutely glandular-pubescent, sub-entire, 1-3 cm. long, 2-5 mm. wide, subsessile; flowers opening 1 to 2 hours before sunrise; hypanthium 5-33 mm. long; sepals 8-12 mm. long, with free tips 1-2 mm. long; petals 5-15 mm. long; $n = 7$; self-incompatible. *Oenothera Tubicula* Gray. Colonial on open slopes and flats in limestone soil, in the Trans-Pecos and adj. cos., Mar.-Sept.; s.e. N.M. and w. Tex. to scattered localities in s. Coah., s. and cen. N.L. and s.w. Tam.

3. *Calylophus Drummondianus* Spach. Bushy to erect perennial or annual, 1-5 dm. tall; leaves linear to oblanceolate, glabrous to canescent, subentire to spinulose-denticulate, 1-8 cm. long, 1-9 mm. wide, subsessile or short-petiolate; flowers opening near sunrise; hypanthium 5-15 mm. long; sepals with sharply raised midrib, 4-10 mm. long, with free tips 0.2-2 mm. long; petals 1-2.5 cm. long, rarely shorter; stigma elevated to or beyond distal end of anthers at anthesis; $n = 7$ (forming pairs or small rings at meiotic metaphase I); self-incompatible. S.e. Colo. and s.w. Kan. through e. N.M., Okla., s.w. La. and Tex. to n. Coah., n.w. N.L. and n. Tam.

Two intergrading subspecies, as follows:

1. Longest stem leaves 34-80 mm. long; plant erect, simple-stemmed, 3-8 dm. high; hypanthium and stigma often black in Texas plants subsp. *Drummondianus*.
1. Longest stem leaves 18-40 mm. long; plant usually bushy, branched from base, 1-4 dm. high; hypanthium and stigma never black subsp. *Berlandieri*.

Subsp. *Drummondianus*. *Oenothera serrulata* var. *Drummondii* T. & G. and var. *spinulosa* auct., p. p. and var. *pinifolia* auct., p. p. Sandy and rocky soil, Edwards Plateau and n.-cen. Tex., Mar.-July; cen. Okla., through cen. Tex. and s.w. La. to mts. of n. Coah. and n.w. N.L.

Subsp. *Berlandieri* (Spach) Towner & Raven. *Oenothera serrulata* var. *serrulata* auct., p. p. and var. *pinifolia* auct., p. p. Sandy soil in Panhandle, n.w. Tex., South Plains and on Gulf Prairies, Mar.-Nov.; s.e. Colo. and s.w. Kan. to e. N.M., w. Okla. and w. and s. Tex.

4. *Calylophus serrulatus* (Nutt.) Raven. YELLOW EVENING PRIMROSE. Similar to preceding but flowers smaller; petals 6-12 mm. long in Tex. (longer in Okla., to 20 mm.); stigma not elevated beyond anthers; anthers shedding pollen directly on the stigma at anthesis, the plants highly autogamous; pollen 30 to 60 percent fertile; $n = 7$ (ring of 14 at meiotic metaphase I). *Oenothera serrulata* Nutt. Infrequent in open sandy or rocky places in the Panhandle and n.-cen. Tex., Apr.-July; n. Tex., e. N.M. and Okla. to Minn., e. Wisc., Sask., Alta. and Man.; also mts. of e.-cen. Ariz. and cen. Chih.

5. *Calylophus australis* Towner & Raven. Similar to *C. Drummondianus* subsp. *Berlandieri* but flowers smaller; petals 8-12 mm. long; stigma not elevated beyond anthers; anthers shedding pollen directly on the stigma at anthesis, the plants highly autogamous; pollen 30 to 60 percent fertile; $n = 7$ (ring of 14 at meiotic metaphase I). *Oenothera serrulata* var. *serrulata* auct., p. p. and var. *pinifolia* auct., p. p. Sandy soil and upper beaches along the Coastal Bend, Mar.-Oct.; coastal Tex. and possibly Tam.

3. GAURA L.

Herbs, sometimes woody near the base, with alternate entire to deeply lobed subsessile leaves; stipules absent; flowers usually zygomorphic, 4-merous or rarely 3-merous, borne in a distinct inflorescence with greatly reduced leaves, usually opening near sunset or sometimes near sunrise; hypanthium well-developed; sepals not persistent in fruit; petals white to pinkish; stamens 8; usually with a scale at the base of each filament inside the hypanthium; stigma deeply 4-lobed or rarely 3-lobed; fruit an indehiscent woody nutlike capsule; seeds lacking a coma.

A genus of 21 species, centering in Texas but ranging north to south-central Canada and south to Guatemala; throughout the eastern United States.

1. Fruit with a slender stipe 3-10 mm. long (2)
1. Fruit subsessile (5)
- 2(1). Plants shrubby, conspicuously and densely soft-villous with long hairs 11. *G. villosa*.
2. Plants herbaceous, not conspicuously and densely soft-villous (3)
- 3(2). Leaves sinuate-pinnatifid, the plants strigulose and villous; south Texas 8. *G. Mckelveyae*.
3. Leaves subentire to sinuate-dentate, the plants subglabrous to strigulose, sometimes villous; widespread (4)

- 4(3). Clumped perennial; apex of the inflorescence in bud slender, the buds small and well-spaced 9. *G. calcicola*.
4. Rhizomatous perennial; apex of the inflorescence in bud stout, the buds large and crowded 10. *G. sinuata*.
- 5(1). Sepals 2-3.5 mm. long; petals 1.5-3 mm. long 1. *G. parviflora*.
5. Sepals 4.5-17 mm. long; petals 3.5-15 mm. long (6)
- 6(5). Fruits fusiform, often curved, 8-17 mm. long, 1-2.5 mm. thick; Trans-Pecos region (7)
6. Fruits variable, 4-13 mm. long, often thicker; widespread (8)
- 7(6). Flowers actinomorphic; hypanthium 9-13 mm. long 2. *G. macrocarpa*.
7. Flowers strongly zygomorphic; hypanthium 5-8.5 mm. long 3. *G. boquillensis*.
- 8(6). Fruits more or less abruptly constricted to a thick cylindrical stipe nearly half the length of the body; perennial species (9)
8. Fruits not abruptly constricted to a thick cylindrical stipe; mostly annual or biennial species from a taproot (10)
- 9(8). Plants from a branching woody caudex; fruits not conspicuously bulging above, 4-8.5 (-9) mm. long, (1-) 1.5-3 mm. thick 4. *G. coccinea*.
9. Plants aggressively rhizomatous; fruits conspicuously bulging above and sharply constricted, 7-13 mm. long, 3-5 mm. thick 5. *G. odorata*.
- 10(8). Flowers 3-merous; fruits 3-angled (11)
10. Flowers 4-merous; fruits 4-angled (12)
- 11(10). Buds very finely strigulose to subglabrous 14. *G. triangulata*.
11. Buds densely strigulose 13. *G. brachycarpa*.
- 12(10). Sepals with long erect hairs; flowers opening near sunrise; petals 10.5-15 mm. long 7. *G. Lindheimeri*.
12. Sepals with appressed or glandular pubescence; flowers opening near sunset; petals 7-15 mm. long (13)
- 13(12). Erect summer- and fall-blooming annual 3-40 dm. tall; fruits thick-fusiform 6. *G. filiformis*.
13. Spring-blooming annuals 2-12 dm. tall; fruits ovoid-pyramidal (14)
- 14(13). Floral parts and inflorescence glabrous 12. *G. suffulta* subsp. *suffulta*.
14. Floral parts and inflorescence pubescent (15)
- 15(14). Floral parts and inflorescence strigulose 13. *G. brachycarpa*.
15. Floral parts and inflorescence glandular-pubescent 12. *G. suffulta* subsp. *Nealleyi*.

1. *Gaura parviflora* Hook. LIZARD-TAIL or VELVET-LEAF GAURA. Rank erect annual (2-) 3-20 (-30) dm. tall, densely glandular-pubescent and sparsely villous, from a heavy taproot; leaves narrowly elliptic to narrowly ovate, 2-12.5 cm. long, 5-40 mm. wide, slightly sinuate-dentate; hypanthium 1.5-4 mm. long, lacking teeth at base of filaments within; sepals 2-3.5 mm. long; petals 1.5-3 mm. long; fruits 5-11 mm. long, 1.5-3 mm. thick, fusiform, sometimes narrowed in lower portion; $n = 7$. Incl. var. *lachnocarpa* Weath. Frequent throughout, often in weedy or cult. situations, but rare in n.e. Tex., Mar.-Nov.; Wash., Mont. and Ind. to Ariz. and La., s. to N.L., Dgo. and Son.; introd. elsewhere.

2. *Gaura macrocarpa* Rothr. Perennial 2-10 dm. tall, with several stems from a branching woody caudex, strigulose with scattered villous pubescence and glandular (more heavily so in the inflorescence); basal leaves spatulate to narrowly oblanceolate, the upper ones narrowly elliptic to narrowly lanceolate, 5-30 mm. long, 1-8 mm. wide, subentire to sinuate-denticulate; flowers actinomorphic; hypanthium 9-13 mm. long; sepals 7-9 mm. long; petals 7-8 mm. long, very broad; fruits 9-17 mm. long, 2-2.5 mm.

thick, fusiform, tapering gradually at both ends; $n = 7$. Sandy flats, local, Brewster, Jeff Davis and Presidio cos., Apr.-July; also Chih.

3. *Gaura boquillensis* Raven & Gregory. Low globose perennial 2.5-10 dm. tall, with many stems from a branching woody caudex, strigulose and also glandular-pubescent (especially in the inflorescence); basal leaves narrowly oblanceolate, the upper ones very narrowly elliptic to narrowly lanceolate, 6-65 mm. long, 1-15 mm. wide, sinuate-dentate to subentire; hypanthium 5-8.5 mm. long; sepals 6.5-9 mm. long; petals 6-10 mm. long; fruits 8-13 mm. long, 1-2.5 mm. thick, fusiform, tapering at both ends, sometimes slightly narrowed in the lower third; $n = 7$. Sandy canyon walls and slopes near the Rio Grande, Brewster Co., Mar.-Aug.; also Coah., Chih. and N.L.

4. *Gaura coccinea* Pursh. SCARLET GAURA. Low well-branched perennial 2-10 dm. tall, with many stems from a branching woody caudex, strigulose or subglabrous; leaves linear to narrowly elliptic, 7-65 mm. long, 1-15 mm. wide, entire to remotely and coarsely serrate; hypanthium 4-11 (-13) mm. long; sepals 5-9 (-10) mm. long; petals 3-7 (-8) mm. long; fruits 4-8.5 (-9) mm. long, (1-) 1.5-3 mm. thick, sharply constricted to a cylindrical stipe below the pyramidal apex; $n = 7, 14, 21, 28$. Incl. var. *glabra* (Lehm.) T. & G., var. *parviflora* (Torr.) T. & G. and var. *epilobioides* (H.B.K.) Munz. Throughout in sandy soils except for e. and s. Tex., rarer eastw., May-Aug.; s.-cen. Can. through the Great Plains to s. Nev., Ariz. and Tex.; throughout Mex. at middle elev.

5. *Gaura odorata* Lag. Low often well-branched perennial 2-6 (-12) dm. tall, with many stems from an aggressively spreading rhizomatous base, strigulose and sometimes with a few longer hairs near the base; leaves narrowly lanceolate to elliptic, 5-75 (-95) mm. long, 1-22 mm. wide, subentire to shallowly sinuate-dentate; hypanthium 4-14 mm. long; sepals 7-11 (-14) mm. long; petals 6-10 mm. long; fruits 7-13 mm. long, 3-5 mm. thick, abruptly constricted from the bulging-pyramidal upper portion to the much narrower cylindrical stipe; $n = 14$. Frequent in sandy soil throughout except for the Plains Country and Trans-Pecos, very rare in e. Tex., Feb.-Nov.; s. to Oax.; introd. elsewhere.

6. *Gaura filiformis* Small subsp. *filiformis*. Tall annual or biennial 3-40 dm. tall, often well-branched in the upper portions, from a stout taproot, strigulose or more rarely glandular in the inflorescence; leaves very narrowly elliptic, those of the main stems 1.5-7 cm. long, 2-13 mm. wide, entire to slightly undulate-denticulate; hypanthium 4-11.5 mm. long; sepals 7-14 mm. long; petals 7-13.5 mm. long; fruits 4.5-6 mm. long, 1.5-2.5 mm. thick, thick-fusiform, 4-angled; $n = 7$. Incl. var. *Kearneyi* Munz, *G. biennis* var. *Pitcheri* of Tex. ref. Open woods and fields, e. and s.-cen. Tex., rare in n.-cen. Tex., June-Dec.; to s. Mo., w. Tenn., and w. Ala.; the species as a whole to Neb., Ia., s. Wisc., s. Minn., N.E. and Md.

7. *Gaura Lindheimeri* Engelm. & Gray. Well-branched perennial 5-15 dm. tall, from a heavy branching woody underground caudex, villous (especially in the inflorescence and also glandular in the inflorescence); leaves very narrowly elliptic, 5-90 mm. long, 1-13 mm. wide, coarsely and remotely serrate; flowers opening near sunrise; hypanthium 4-9 mm. long; sepals 8.5-17 mm. long; petals 10.5-15 mm. long; fruits 6-9 mm. long, 2-3.5 mm. thick, thick-fusiform, 4-angled; $n = 7$. *G. filiformis* var. *Munzii* Cory. Common in black-soil prairie in s.-cen. and s.e. Tex., Apr.-Nov.; also s. La.; widely cult. and occasionally established elsewhere.

8. *Gaura Mckelveyae* (Munz) Raven & Gregory. Low perennial 2-5 dm. tall, from a woody caudex, strigulose and villous; leaves narrowly elliptic to narrowly oblanceolate, 1-6.5 cm. long, 1-15 mm. wide, deeply to more shallowly sinuate-pinnatifid; hypanthium 2-3.5 mm. long; sepals 6-12 mm. long; petals 7-10.5 mm. long; fruits 8-19 mm. long, 1.5-2 mm. wide, with a slender stipe 3-9 mm. long; $n = 7$. *G. villosa* var. *Mckelveyae* Munz. Locally frequent in sandy soil, s. Tex., Mar.-Aug.; also N.L. and Tam.

9. *Gaura calcicola* Raven & Gregory. Clumped perennial 3-8 dm. tall, from a branching woody caudex, subglabrous to strigulose and/or villous; leaves linear to narrowly oblanceolate, 1-12 cm. long, 1-10 mm. wide, subentire to sinuate-dentate; hypanthium 3-9 mm. long; sepals 6-12 mm. long; petals 3-6.5 mm. long; fruits 7-12 mm. long, 1.5-2.5 mm. thick, with a slender stipe 2-5 mm. long; $n = 7$. *G. sinuata* of auth., in part. Rocky banks and flats, usually in limestone soil, Trans-Pecos, Edwards Plateau, n. Rio Grande Plains and s. border of the South Plains, to Callahan and McCulloch cos., Apr.-June (-Oct.); also Coah., Tam., N.L., and n. Dgo.

10. *Gaura sinuata* Sér. WAVY-LEAVED GAURA. Aggressively spreading rhizomatous perennial 2-6 dm. tall, subglabrous to strigulose or more rarely with scattered villous pubescence; leaves linear to narrowly oblanceolate, 1-11 cm. long, 1-20 mm. wide, sinuate-dentate; hypanthium 2.5-5 mm. long; sepals 7-14 mm. long; petals 7-14.5 mm. long; fruits 8-15 mm. long, 1.5-3.5 mm. thick, with a slender stipe 3-8 mm. long; $n = 14$. Frequent in open sandy or often disturbed places throughout, except for the High Plains and Trans-Pecos, Mar.-June; also Okla.; widely introd. elsewhere.

11. *Gaura villosa* Torr. WOOLLY GAURA. Bushy perennial 6-18 dm. tall, with many erect wandlike branches from the woody base, densely villous (especially in the basal portions); leaves linear to narrowly lanceolate, 5-80 mm. long, 1.5-20 mm. wide, sinuate-dentate to subentire; hypanthium 1.5-5 mm. long; sepals 6-14 mm. long; petals 8.5-13 mm. long; fruits 9-19 mm. long, 2-3.5 mm. thick, with a slender stipe 2-10 mm. long.

Consists of the following two subspecies:

Subsp. *villosa*. Pubescence with an understory of glandular or strigulose hairs, these often predominant in the inflorescence; inflorescence not conspicuously umbellate-branching; $n = 7$. *G. villosa* var. *arenicola* Munz. Scattered but locally frequent on open sandy flats and dunes throughout the Plains Country, infrequent southw. to the rim of the Edwards Plateau, May-Sept.; to e. N.M., s.w. Kan. and cen. and w. Okla.

Subsp. *Parksii* (Munz) Raven & Gregory. Pubescence of inflorescence of short dense spreading hairs; inflorescence conspicuously umbellate-branching; $n = 7$. Scattered but colonial on sand deposits, Rio Grande Plains, Apr.-Oct.; endemic.

12. *Gaura suffulta* Gray. WILD HONEYSUCKLE, BEE BLOSSOM, KISSES. Well-branched annual 2-12 dm. tall, from a stout taproot, villous in the lower portions; leaves narrowly lanceolate to lanceolate, 1-9.5 cm. long, 1-23 mm. wide, subentire to sinuate-dentate; hypanthium 6.5-14 mm. long; sepals 11-21 mm. long; petals 10-15 mm. long; fruits 4.5-8 mm. long, 2-4.5 mm. thick, ovoid-pyramidal. Consists of the following two subspecies:

Subsp. *suffulta*. Floral parts and inflorescence glabrous; bracts mostly 4.5-7 mm. long; $n = 7$. Common in open sandy often weedy situations throughout except for the Trans-Pecos, but rare in e. and s. Tex., Apr.-June; to Okla.

Subsp. *Nealleyi* (Coul.) Raven & Gregory. Floral parts and inflorescence glandular-pubescent; bracts 2-5 mm. long; $n = 7$. *G. Nealleyi* Coul., *G. suffulta* var. *terrellensis* Munz, *G. gracilis* and its var. *glandulosa* of Tex. ref. Common in sandy places in the Trans-Pecos, Apr.-Oct.; to s. N.M. and n. Coah.

13. *Gaura brachycarpa* Small. Low well-branched annual, sometimes persisting through mild winters, 15-65 cm. tall, from a slender taproot, villous, strigulose in the inflorescence; leaves narrowly lanceolate to oblanceolate, 1-7 cm. long, 1-16 mm. wide, subentire to slightly sinuate-denticulate; flowers rarely 3-merous; hypanthium 6.5-12 mm. long; sepals 10-15 mm. long; petals 8-12.5 mm. long; fruits 6-9 mm. long, 2-3 mm. thick, usually auriculate near the base with a stipe about 1 mm. long; $n = 7$. *G. tripetala* Cav. var. *Coryi* Munz. Frequent and colonial in open sandy places throughout cen. and e. Tex., Feb.-June; rare and perhaps introd. in Okla., La. and s. Miss.

14. *Gaura triangulata* Buckl. Erect slender annual 1.5-6 dm. tall, usually with several branches near the base, from a slender taproot, villous, lightly strigulose or subglabrous in the inflorescence; leaves very narrowly elliptic to oblanceolate, 1.5-8 cm. long, 2-15 mm. wide, subentire to slightly sinuate-dentate; flowers 3-merous; hypanthium 4-5.5 mm. long; sepals 4.5-6 mm. long; petals 3.5-5 mm. long; fruits 7-9 mm. long, 3-5 mm. thick; $n = 7$ (complete ring of 14 chromosomes at meiotic metaphase I). *G. tripetala* Cav. var. *triangulata* (Buckl.) Munz. Sandy open places, n.-cen. Tex., Mar.-June; also widespread in Okla.

4. OENOTHERA L. EVENING PRIMROSE

Herbs, sometimes woody near the base, with alternate entire to pinnatifid leaves; stipules absent; flowers actinomorphic, 4-merous, borne in the axils of upper leaves or in a more or less distinct inflorescence, opening either near sunset or near sunrise; hypanthium well-developed; sepals not persistent in fruit; petals yellow or white to rose-purple; stamens 8; stigma deeply 4-lobed; fruit a loculicidally dehiscent or nutlike indehiscent capsule; seeds lacking a coma.

About 80 species of the temperate regions of North America and South America, widely introduced elsewhere.

1. Capsule clavate, the lower part narrowed and stipelike; seeds clustered, not in definite rows (2)
1. Capsule ovoid to cylindrical; seeds usually in definite rows (9)
- 2(1). Flowers white or rose-purple (3)
2. Flowers yellow (7)
- 3(2). Inflorescences sharply nodding; capsule with the lower part sterile and cylindrical, sessile 5. *O. speciosa*.
3. Inflorescences erect; capsule tapering, pedicellate (4)
- 4(3). Petals white, fading pinkish; flowers opening near sunset (5)
4. Petals rose; flowers opening near sunrise (6)
- 5(4). Hypanthium 15-21 mm. long; petals 12-21 mm. long 3. *O. texensis*.
5. Hypanthium 4-8 mm. long; petals 4.5-12 mm. long 4. *O. rosea*.
- 6(4). Stigma usually elevated above the anthers; hypanthium 10-30 long; petals 20-35 mm. long 1. *O. tetraptera*.
6. Stigma surrounded by the anthers; hypanthium (5-) 20 mm. long; petals 10-20 mm. long 2. *O. Kunthiana*.
- 7(2). Hypanthium 1.5-2 mm. long; petals 3-5 mm. long .. 8. *O. linifolia*.
7. Hypanthium 4-17 mm. long; petals 5-20 mm. long (8)
- 8(7). Hypanthium 4-6 mm. long; annual 7. *O. Spachiana*.
8. Hypathium 10-17 mm. long; perennial 6. *O. sessilis*.
- 9(1). Capsule ovoid-pyramidal or oblong-ovoid, indehiscent; low rhizomatous herbs (10)
9. Capsule subcylindrical, readily dehiscent at maturity (at least at the apex) (11)
- 10(9). Hypanthium 40-55 mm. long; petals 15-30 mm. long 9. *O. Havardii*.
10. Hypanthium 5-15 mm. long; petals 8-12 mm. long ...10. *O. canescens*.
- 11(9). Flowers white (12)
11. Flowers yellow (15)
- 12(11). Mature buds erect; mature capsules 6-10 mm. thick, conspicuously tuberculate-ridged14. *O. caespitosa*.
12. Mature buds drooping; mature capsules 1-3 mm. thick, not conspicuously tuberculate-ridged (13)
- 13(12). Plants rhizomatous, perennial23. *O. pallida*.
13. Plants annual, from a slender taproot (14)
- 14(13). Stems densely and uniformly covered with villous pubescence; petals 1-1.5 cm. long; seeds in 1 row in each locule22. *O. Engelmannii*.
14. Stems strigulose or sparsely villous; petals 1.5-4 cm. long; seeds in 2 rows in each locule21. *O. albicaulis*.
- 15(11). Capsule conspicuously winged on the angles, at least above (16)
15. Capsule not winged (18)
- 16(15). Capsule winged above, obpyramidal; petals 1-2 cm. long; winter annual 13. *O. triloba*.
16. Capsule broadly winged its entire length; petals 2-5 cm. long; perennial (17)
- 17(16). Plants acaulescent; wings of capsule 1.5-4.5 mm. wide; leaves subentire to pinnatifid12. *O. brachycarpa*.
17. Plants usually caulescent, the stems to 5 dm. long; wings of capsules 7-20 mm. wide; leaves subentire or remotely denticulate11. *O. missouriensis*.

- 18(15). Acaulescent annual with thick-walled capsules; seeds with a deep groove surrounding the raphe 15. *O. primiveris*.
18. Caulescent annuals or perennials; seeds lacking a deep groove surrounding the raphe (19)
- 19(18). Seeds horizontal, sharply angled; capsule gradually tapered upward (20)
19. Seeds ascending, not sharply angled; capsule oblong-fusiform to subclavate (22)
- 20(19). Petals 1-2 cm. long; styles mostly 0.3-1.7 mm. long 26. *O. biennis*.
20. Petals 2-5 cm. long; styles 20-60 mm. long (21)
- 21(20). Hypanthium 25-45 mm. long 24. *O. Hookeri*.
21. Hypanthium 60-110 mm. long 25. *O. Jamesii*.
- 22(19). Flowers in terminal spikes, the upper leaves reduced to bracts; stems erect (23)
22. Flowers in upper leaf axils; stems erect or more or less decumbent (24)
- 23(22). Petals rhombic-obovate, 13-20 mm. long; free sepal tips 0.5-1.5 mm. long; bracts lanceolate 17. *O. rhombipetala*.
23. Petals obovate, 16-30 mm. long; free sepal tips 2-4 mm. long; bracts ovate or lanceolate 18. *O. heterophylla*.
- 24(22). Plants densely invested with canescent-villous pubescence, with numerous more or less woody stems from the base; coastal sands 16. *O. Drummondii*.
24. Plants loosely villous, the stems not woody (25)
- 25(24). Sepals 5-12 mm. long; petals 5-18 mm. long 20. *O. laciniata*.
25. Sepals 20-30 mm. long; petals 20-35 mm. long 19. *O. grandis*.

1. *Oenothera tetraptera* Cav. Well-branched strigulose to hirsute annual to 4 dm. tall; leaves sinuate to sinuate-pinnatifid, the upper ones subentire, lanceolate to oblanceolate or occasionally narrowly elliptic, 1-9 cm. long, (2-) 10-25 mm. wide, the petiole 2-20 mm. long; flowers opening near sunset; mature buds erect; hypanthium 1-3 cm. long; sepals 2-4 cm. long, with free tips to 3 mm. long; petals white, fading pink, 2-3.5 cm. long; pollen fertile; capsule obovoid, 1-2 cm. long, on a pedicel (4-) 10-45 mm. long; seeds in several indistinct rows in each locule, 1.2-1.5 mm. long; $n = 7$ (forming bivalents at meiosis). Gravel bars, alluvial flats and open places, rare and scattered, s. and w. Tex., Mar.-May; to Col. and w. Venez.; cult. and naturalized elsewhere.

2. *Oenothera Kunthiana* (Spach) Munz. Similar in general to *O. tetraptera*; plants subglabrous to strigulose; hypanthium (0.5-) 1-2 cm. long; sepals 5-20 mm. long, with tips coherent at anthesis; petals 1-2 cm. long; pollen approximately 50% sterile; $n = 7$ (ring of 14 in meiosis). Gravel bars and flat sandy often weedy places in the Trans-Pecos, Edwards Plateau and s. Tex., Feb.-May; s. to C. R.

3. *Oenothera texensis* Raven & Parnell. Well-branched strigulose or rarely hirsute perennial herb, flowering the first year, to 5 dm. tall; leaves serrulate to sinuate-pinnatifid, elliptic to ovate, 2.5-4 cm. long, 8-18 mm. wide, the petiole 4-21 mm. long; flowers opening near sunrise; mature buds erect; hypanthium 15-21 mm. long; sepals 15-18 mm. long, lacking free tips; petals rose, 12-21 mm. long; pollen fertile; capsule obovoid, 8-14 mm. long, on a pedicel 7-12 mm. long; seeds in several indistinct rows in each locule, 0.8-1 mm. long; $n = 7$ (forming bivalents at meiosis). Gravel bars and along streams in canyons, Jeff Davis Co. in the Trans-Pecos, May-Aug.; s. to Sin., Coah. and Tam.

4. *Oenothera rosea* Ait. ROSE SUNDROPS. Well-branched strigulose or rarely hirsute perennial herb, flowering the first year, to 4 dm. tall; leaves subentire or sinuate-pinnatifid, elliptic or rarely narrowly ovate, 2-5 cm. long, 1-2.5 cm. wide, the petiole 2-25 mm. long; flowers opening near sunrise; mature buds erect; hypanthium 4-8 mm. long; sepals 7-12 mm. long, lacking free tips; petals rose, 4-12 mm. long; pollen approximately 50% sterile; capsule obovoid, 5-10 mm. long, on a pedicel 4-8 mm. long; seeds in several indistinct rows in each locule, 0.7-0.9 mm. long; $n = 7$ (ring of 14 in meiosis). Along creeks and in low weedy places, Trans-Pecos, Edwards Plateau and s. Tex., Apr.-Aug.; s. to Arg., a pan-trop. weed.

5. *Oenothera speciosa* Nutt. s. lat. AMAPOLA DEL CAMPO, SHOWY PRIMROSE. Rhizomatous strigulose perennial to 5 dm. tall; leaves subentire to (usually) sinuate-pinnatifid, obovate to oblong-lanceolate, 2-9 cm. long, 4-25 mm. wide, the petiole to 3 cm. long; inflorescence sharply nodding; hypanthium 1-2 cm. long; sepals 1.5-3 cm. long, with free tips 1-4 mm. long; petals white or rose-purple, 2.5-4 cm. long; capsule narrowly obovoid, very tough, 1-1.5 cm. long, sessile; seeds in several indistinct rows in each locule, about 1 mm. long; $n = 7, 14, 21$. Incl. var. *Childsii* (Bailey) Munz. Prairies and open woodlands, throughout Tex. but rare and scattered to the n. and w., Apr.-July; Kan. and Mo. to n.e. Mex.

More northern populations of this species tend to be white-flowered, evening-opening and diploid ($n = 7$), whereas the southern populations which are widespread in cultivation and often naturalized are more often rose-purple flowered morning-opening and polyploid ($n = 14, 21$). These latter have been separated as *O. Delessertiana* Steud., but white-flowered, evening-opening plants occur in polyploid populations and a taxonomic separation of these two series of plants would appear to be more confusing than helpful. Both forms, with intermediates between them, are common in Texas.

6. *Oenothera sessilis* (Penn.) Munz. Densely strigose sparsely branched perennial with short rootstalks, the stems to 5 dm. tall; leaves denticulate, lanceolate, 3-6 cm. long, 4-9 (-15) mm. wide, subsessile; flowers opening near sunrise; mature buds erect; hypanthium 1-1.7 cm. long; sepals 1-2 cm. long, with free tips 1-2 mm. long; petals yellow, 1-2 cm. long; capsule linear-clavate, 8-10 mm. long, subsessile; seeds in several indistinct rows in each locule, about 0.8 mm. long. Marshy places, Galveston I., *Lindheimer* (US), Nov.; to s. Ark. and adj. La. Last collected in Texas 115 years ago!

7. *Oenothera Spachiana* T.&G. Erect strigulose annual to 5 dm. tall; leaves subentire, narrowly elliptic to elliptic, 2-5 cm. long, 4-10 mm. wide, short-petioled; flowers opening near sunrise; mature buds erect; hypanthium 4-6 mm. long; sepals 8-10 mm. long, with free tips 1-1.5 mm. long; petals yellow, 5-15 mm. long; capsule clavate, 8-10 mm. long, more or less stipitate; seeds in several indistinct rows in each locule, about 0.6 mm. long; $n = 7$. Open sandy prairies and low ground, e. Tex., Apr.-May; to w. La., Ark. and s.e. Okla.

8. *Oenothera linifolia* Nutt. THREE-LEAVED SUNDROPS. Erect slender subglabrous annual to 3 dm. tall; leaves entire, filiform, 1-2.5 cm. long, to 3 mm. wide, subsessile (except for the broader basal ones); flowers opening near sunrise; mature buds erect; hypanthium 1.5-2 mm. long; sepals 1.5-2 mm. long, lacking free tips; petals yellow, 3-5 mm. long; capsule short-clavate, 4-6 mm. long, short stipitate; seeds in several indistinct rows in each locule, about 1 mm. long; $n = 7$. Sandy slopes and flats, often in open woods, e. Tex., Apr.-May; to Kan., s. Ill., Ala. and n. Ga.

9. *Oenothera Havardii* Wats. Cespitose bushy subglabrous to strigulose rhizomatous perennial with stems to 1 dm. long; leaves narrowly lanceolate to oblanceolate, the cauline ones 1-3.5 cm. long and 2-5 mm. wide, sinuate-pinnatifid, subsessile, the basal ones larger; flowers opening near sunset; mature buds erect; hypanthium 4-5.5 cm. long; sepals 15-25 mm. long, with free tips 0-1.5 mm. long; petals yellow, fading reddish, 1.5-3 cm. long; capsule oblong-ovoid, 1-1.5 cm. long, 4-angled, the valves strongly ribbed; seeds in several rows in each locule, about 2 mm. long; $n = 7$. Rare and local in sandy soil in the s. Trans-Pecos, May-Sept.; to s. Ariz. (where perhaps introd.) and s. to Chih. and Dgo.

10. *Oenothera canescens* Torr. & Frém. SPOTTED PRIMROSE. Low bushy densely strigulose to canescent rhizomatous perennial with stems to 2 dm. long; leaves denticulate, lanceolate, 5-15 mm. long, 2-7 mm. wide, subsessile; flowers opening near sunset; mature buds erect; hypanthium 5-15 mm. long; sepals 8-14 mm. long, lacking free tips; petals pinkish or more rarely white on first opening, 8-12 mm. long, red-spotted all over; capsule ovoid-pyramidal, sharply 4-angled, beaked, 7-8 mm. long; seeds in several rows in each locule, about 1 mm. long; $n = 7$. Dried up ponds and lakes in clay soil, Edwards Plateau n. through the Panhandle, local, May-Aug.; to N.M. and n. on the Plains to Neb. and Wyo.

11. *Oenothera missouriensis* Sims. MISSOURI PRIMROSE, GLADE-LILY. Perennial, the stems to 5 dm. long or more rarely the plants subcaulescent; leaves narrowly lanceolate or elliptic to broadly lanceolate, 3-10 cm. long, 5-30 mm. wide, subentire to remotely denticulate, glabrous to densely canescent, the petioles 1-5 cm. long; flowers opening near sunset; mature buds erect; hypanthium 5-12 cm. long; sepals 2-4 cm. long, with free

tips 1.5-8 mm. long; petals yellow, sometimes fading reddish, 2-5 cm. long; capsule 2-6.5 cm. long, with 4 wings 7-20 mm. wide; seeds in 1 row in each locule, 3-4 mm. long, corky-tubercled. Incl. var. *incana* Gray and var. *oklahomensis* (Nort.) Munz. Limestone knobs, prairies and dry hillsides, n.-cen. Tex. and the Edwards Plateau, n. through the the High Plains, May-Aug.; n. through Okla., w. Ark. and w. Mo. to Kan. and Neb.

12. *Oenothera brachycarpa* Gray. Subcaulescent perennial; leaves linear to narrowly ovate, 3-15 cm. long, 1-3 cm. wide, entire to sinuate-dentate, glabrous to more or less densely strigulose; petioles 1-6 cm. long; flowers opening near sunset; mature buds erect; hypanthium 5-15 cm. long; sepals 3-4 cm. long, with free tips 1-4 mm. long; petals yellow, fading reddish, 3-5 cm. long; capsule broadly fusiform, 2.5-3 cm. long, with 4 wings 1.5-4.5 mm. wide only near the summit or along the entire body; seeds in one row in each locule, 2-4 mm. long, corky-tubercled at least near the apex and base; $n = 7$. Incl. var. *Wrightii* H. Lévl. Rocky slopes from the El Paso area e. through the Trans-Pecos to the s. part of the South Plains and to Callahan Co., Mar.-June; s.w. Ida. and Colo. s. to Ariz., w. Tex., Chih., Coah. and Dgo.

13. *Oenothera triloba* Nutt. Subcaulescent winter annual or biennial; leaves elliptic to oblanceolate, 3-30 cm. long, 1-4 cm. wide, irregularly pinnatifid, glabrous to strigulose or finely glandular-pubescent; petioles 1-2 (-8) cm. long; flowers opening near sunset; mature buds erect; hypanthium 2-10 cm. long; sepals 1-1.8 cm. long, with free tips 3-7 mm. long; petals pale-yellow, 1-2 cm. long; capsule obpyramidal, very hard, 1-2 cm. long, with 4 wings 5-10 mm. wide near the summit; seeds in 2 rows in each locule, about 2 mm. long, narrowly winged near the summit. Grassy slopes and open flats, particularly where moist, n.-cen. Tex. and Edwards Plateau, rare s. to Hidalgo Co., Feb.-May (-July); Kan. to Ky., Tenn. and n. Ala., s. to Tex.

14. *Oenothera caespitosa* Nutt. subsp. *eximia* (Gray) Munz. Stout pilose perennial with stems to 3 dm. long; leaves subentire to sinuate-pinnatifid, oblanceolate, 3-12 cm. long, 1-2 cm. wide, the petioles 2-8 cm. long; flowers opening near sunset; mature buds erect; hypanthium 10-15 cm. long; sepals 25-35 mm. long, with tips appressed in bud; petals white, fading rose-purple, 2.5-4 cm. long; capsule lance-ovoid, hard, tuberculate, 2.5-4 cm. long; seeds in 2 rows in each locule, about 3 mm. long. Rocky slopes in the mts. of the Trans-Pecos, very rare, Culberson Co., June; e. Colo. to w. Tex. and n. N.M.

15. *Oenothera primiveris* Gray. LARGE YELLOW DESERT PRIMROSE. Subcaulescent annual; leaves narrowly elliptic to broadly oblanceolate, 2-12 cm. long, 5-30 mm. wide, irregularly pinnatifid or (rarely) subentire, villous throughout; petioles 5-50 mm. long; flowers opening near sunset; mature buds erect; hypanthium 2-6 cm. long; sepals 1-2.8 cm. long, without free tips; petals lemon-yellow, fading reddish, 1-4 cm. long; capsule broadly fusiform, 1.7-4 cm. long, with a heavy rib down the center of each face; seeds in 2 rows in each locule, 2.5-3 mm. long, with narrow groove surrounding the raphe; $n = 7$. Desert flats in the Trans-Pecos, Mar.-Apr.; w. to s.w. Ut., s. Nev., s. Calif. and n. Son.

16. *Oenothera Drummondii* Hook. BEACH EVENING PRIMROSE. Suffrutescent densely canescent-villous perennial with many woody stems to 1 m. long from the base; leaves oblanceolate to obovate, 1-7 cm. long, 5-15 mm. wide, entire or remotely sinuate-dentate (especially the larger basal ones), densely canescent-villous throughout; petioles 0-3 cm. long; flowers opening near sunset; mature buds erect; hypanthium 2-4 cm. long; sepals 2-3 cm. long, with free tips 2-3 mm. long; petals yellow, fading reddish, 2-3.5 cm. long; capsule cylindrical, 2.5-4 cm. long; seeds in 2 rows in each locule, 1-1.2 mm. long; $n = 7$. Sandy beaches of entire Gulf Coast, Mar.-Nov.; s. to Ver.; introd. widely elsewhere.

17. *Oenothera rhombipetala* T.&G. Erect strigulose winter annual or biennial from a fleshy taproot, the stems to 1 m. tall; leaves narrowly oblanceolate to narrowly ovate (broader above), 2-8 cm. long, 3-15 mm. wide, sinuate-pinnatifid to subentire; petioles short or absent; flowers opening near sunset; mature buds erect; hypanthium 2.5-3 cm. long; sepals 1-1.8 cm. long, with free tips 0-1.5 mm. long; petals yellow, 1.3-2 cm. long; capsule cylindrical, 12-16 mm. long; seeds in 2 rows in each locule, about 1 mm. long; $n = 7$. Common in sandy and waste places, e. half of Tex., June-Sept.; Ind. to Wisc. and Minn. s. to Tex. and scattered (possibly introd.) e. to the Atl. Coast.

18. *Oenothera heterophylla* Spach. Erect hirsute and strigulose winter annual or biennial from a fleshy taproot, the stems to 1 m. tall; leaves 2-9 cm. long, 3-15 mm. wide, sinuate-pinnatifid to subentire, the upper ones sessile with clasping base; flowers opening

near sunset; mature buds erect; hypanthium 2.5-3 cm. long; sepals 1.5-2 cm. long, with free tips 3-4 mm. long; petals yellow, 1.6-3 cm. long; capsule cylindrical, 15-25 mm. long; seeds in 2 rows in each locule, about 1 mm. long; $n = 7$. Colonial in sandy open woods, e. and n.-cen. Tex., June-Sept.; also w. La.

19. *Oenothera grandis* (Britt.) Smyth. Erect simple or much-branched decumbent strigulose and sometimes villous annual, the stems to 8 dm. long; leaves elliptic to oblanceolate, 2-6 cm. long, 5-15 mm. wide, sinuate-pinnatifid or rarely less deeply lobed or entire, subglabrous to strigulose or villous; petioles 0.5 cm. long, mostly short; flowers opening near sunset; mature buds erect, the stem tip nodding; hypanthium 2.5-5 cm. long; sepals 2-3 cm. long, with free tips 2-5 mm. long; petals yellow, 2-3.5 cm. long; capsule cylindrical, 1-3.5 cm. long; seeds in 2 rows in each locule, about 1 mm. long; $n = 7$ (forming pairs or small rings at meiotic metaphase I). *O. laciniata* var. *grandiflora* (Wats.) Robins. Sandy open places, scattered in e., cen. and s. Tex. and in the South Plains, Mar.-June; Kan. and Mo. to Chih., Dgo., Zac. and Tam.

20. *Oenothera laciniata* Hill. CUT-LEAVED EVENING PRIMROSE. Similar to *O. grandis* but the hypanthium 15-35 mm. long; sepals 5-12 mm. long, with free tips 0-2 mm. long; petals 5-18 mm. long; $n = 7$ (ring of 14 chromosomes at meiotic metaphase I). Incl. var. *pubescens* (Willd.) Munz. Sandy fields and waste places throughout except for the South Plains, rarer in the w. and Panhandle, Mar.-Nov.; e. U.S. s. to Ecu.

Apparent hybrids with *O. Drummondii* occur where the ranges of these two very distinct species overlap.

21. *Oenothera albicaulis* Pursh. PRAIRIE EVENING PRIMROSE. Erect strigulose and more or less villous annual, often with additional decumbent branches from the base, the stems to 5 dm. long; leaves elliptic to oblanceolate, 1-8 cm. long, 5-20 mm. wide, sinuate-pinnatifid or the lower ones subentire, strigulose and more or less villous; petioles 0-4 cm. long, mostly short; flowers opening near sunset; mature buds nodding; hypanthium 1.5-3 cm. long; sepals 14-25 mm. long; petals white, fading pink, 1.4-4 cm. long; capsule cylindrical, 2-4 cm. long; seeds in 2 rows in each locule, about 1 mm. long; $n = 7$. Sandy places in the Trans-Pecos, South Plains and Panhandle, Apr.-June; S.D. and Mont. to Tex., Chih., Ariz. and s. Ut.

22. *Oenothera Engelmannii* (Small) Munz. Erect densely villous annual to 8 dm. tall, usually with one main stem from the base, the lateral branches poorly developed; leaves lanceolate, 2-6 cm. long, 1-2 cm. wide, coarsely sinuate-dentate, more or less villous, sessile; flowers opening near sunset; mature buds nodding; hypanthium 2-3 cm. long; sepals 1-1.5 cm. long, lacking free tips; petals white, fading pink, 1-1.5 cm. long; capsule tapering gradually to the apex, 25-45 mm. long; seeds in 1 row in each locule, about 1 mm. long; $n = 7$. Sand dunes and open sandy flats in the South Plains, May-Sept.; to e. N.M.

23. *Oenothera pallida* Lindl. subsp. *runcinata* (Engelm.) Munz & Klein. Bushy much-branched subglabrous to strigulose or sometimes pilose rhizomatous perennial to 4 dm. tall; leaves narrowly lanceolate to ovate, 2-3.5 cm. long, 4-15 mm. wide, deeply sinuate-dentate to sinuate-pinnatifid or more rarely subentire, subglabrous to strigulose, subsessile; flowers opening near sunset; mature buds nodding; hypanthium 1.5-3 cm. long; sepals 1-2.5 cm. long, lacking free tips; petals white, fading pink, 1-2.5 cm. long; capsule cylindrical, 1.5-6 cm. long; seeds in 1 row in each locule, about 1.5 cm. long; $n = 7$. *O. runcinata* (Engelm.) Munz and var. *brevifolia* (Engelm.) Munz, *O. latifolia* sensu Munz, Fl. Tex. 3: 232. 1944. Sandy open or disturbed places in the Trans-Pecos, Apr.-Oct.; s. Ut. to Ariz., w. Tex. and Chih.; the species as a whole from e. Wash., Ida. and Wyo. s. to this area.

24. *Oenothera Hookeri* T.&G. Robust erect biennial or perennial to 2 m. tall; leaves oblanceolate to elliptic, densely strigose and sometimes also pilose, entire to sinuate-serrulate, the rosette leaves narrower near the base, 1-3 dm. long, 2-5 cm. wide, their petioles 5-18 cm. long, the cauline leaves 5-15 cm. long and 8-25 mm. wide, short-petioled to subsessile; flowers opening near sunset; mature buds erect; hypanthium 25-45 mm. long; sepals 2.5-4 cm. long, with free tips 2-6 mm. long; petals yellow, fading reddish, 2-4.5 cm. long; capsule thick, cylindrical, 2-4 cm. long; seeds in 2 rows in each locule, 1-1.6 mm. long; $n = 7$. S.e. Wash. and s. Ida. to Baja Calif., Kan., Tex. and Chih.

In Texas represented by 2 subsp. as follows:

Subsp. *hirsutissima* (Gray) Munz. Pubescence largely loose with some spreading hairs; free sepal tips 2-4 (-5) mm. long; seeds 1.2-1.6 mm. long; $n = 7$. Rare in wet places in the Trans-Pecos, July-Oct.; Ut. and s. Colo. to w. Kan., Chih. and Son.

Subsp. *Hewettii* Cockll. Pubescence appressed; free sepal tips 3-6 mm. long; seeds about 1 mm. long; $n = 7$. Incl. var. *irrigua* (Woot. & Standl.) Gates, *O. Simsiana sensu* Munz, Fl. Tex. 226. 1944. Rare in wet places in the Trans-Pecos, July-Oct.; Nev. and s. Ut. to Tex. and Chih.

25. *Oenothera Jamesii* T.&G. Robust erect densely appressed-pubescent biennial to 2 m. tall; leaves elliptic to broadly lanceolate, appressed-pubescent; rosette leaves narrower near the base, sinuate-pinnatifid to denticulate, 6-20 cm. long and 2-4 cm. wide, their petioles 2-6 cm. long; cauline leaves denticulate, 5-12 cm. long and 2-3.5 cm. wide, short-petioled below to subsessile above; flowers opening near sunset; mature buds erect; hypanthium 6-11 cm. long; sepals 4-6 cm. long, with free tips 3-6 mm. long; petals yellow, fading reddish, 3.5-5 cm. long; capsule thick, cylindrical, 2-5 cm. long; seeds in 2 rows in each locule, 1.5-2 mm. long; $n = 7$. On stream banks in wet places, scattered, Edwards Plateau and Llano area w. to the Trans-Pecos, July-Oct.; Okla. and w. Tex. to Coah.

26. *Oenothera biennis* L. subsp. *centralis* Munz. COMMON EVENING PRIMROSE. Weedy sparsely pubescent biennial to 2 m. tall; leaves lanceolate; rosette leaves sinuate-pinnatifid to denticulate, 8-30 cm. long and 1-6 cm. wide, their petioles long; cauline leaves denticulate, 5-16 cm. long, 15-35 mm. wide, subsessile; flowers opening near sunset; mature buds erect; hypanthium 2-5 cm. long; sepals 1-2 cm. long; the free tips 1-4 mm. long; petals yellow, 1-2 cm. long; capsule thick, cylindrical, 14-25 mm. long; seeds in 2 rows in each locule, 1.2-1.8 mm. long; $n = 7$ (ring of 14 chromosomes at meiotic metaphase I). *O. pratincola* Bartlett. Weedy places and woods, scattered, n.e. Tex., Aug.-Oct.; Alta. to Wisc. and Mich., s. to Tex. and La. and e. to Atl. Coast; the species as a whole ranges to Nfld., Que. and Ont.

Two species have been reported from Texas for which we have seen no material; they are: (1) *Oenothera coronopifolia* T.&G., related to *O. albicaulis* but it is perennial from slender underground rootstocks, has throat of hypanthium with conspicuous white hairs and petals 7-11 mm. long; (2) *Oenothera neomexicana* (Small) Munz, related to *O. Engelmannii* but it has capsules quite erect, not woody, and 2-3 cm. long, petals 2-3 cm. long and the lower leaves (at least) petioled.

5. STENOSIPHON SPACH

A monotypic genus.

1. *Stenosiphon linifolius* (Nutt.) Heynh. Tall virgate perennial herb, somewhat woody near the base, to 3 m. tall, unbranched or with few long branches, glabrous and glaucous; stipules absent; leaves entire, alternate, lanceolate or narrowly lanceolate, 2-6 cm. long, 4-15 mm. wide, sessile; flowers actinomorphic, 4-merous, borne in a more or less distinct wandlike inflorescence with greatly reduced leaves, opening near sunrise; hypanthium well-developed, filiform, 7-11 mm. long; sepals not persistent in fruit, 4-5 mm. long; petals white, 4-5 mm. long; stamens 8; stigma deeply 4-lobed; fruit an indehiscent obovoid nutlike 1-seeded capsule 2-3 mm. long and about 2 mm. thick, 8-ribbed; seeds lacking a coma; $n = 7$. Rocky banks and slopes, usually on limestone, colonial, from the Edwards Plateau n. through n.-cen. Tex. and the Panhandle, June-Oct.; n. to s. Neb. and w. Ark.

6. LUDWIGIA L. SEEDBOX. WATER-PRIMROSE

Herbs of wet places with alternate or opposite entire or minutely toothed leaves; stipules present, minute; flowers actinomorphic, 4- or 5- (rarely 6-) merous, borne in the axils of upper leaves; hypanthium not prolonged beyond the apex of the ovary; sepals persistent in fruit; petals yellow or absent; stamens as many or twice as many as the sepals; stigma capitate or globose, undivided; fruit a loculicidally or poricidally dehiscent capsule; seeds lacking a coma. *Jussiaea* L.

About 70 species, mostly of the tropics and subtropics and best represented in tropical South America.

- 1. Leaves opposite (2)
- 1. Leaves alternate (3)
- 2(1). Petals absent; capsule with a broad green band at each corner 11. *L. palustris*.
- 2. Petals present; capsule lacking green bands 12. *L. repens*.
- 3(1). Stamens twice as many as the sepals, in 2 series (4)
- 3. Stamens as many as the sepals, in 1 series (8)
- 4(3). Stems conspicuously 4-winged 1. *L. decurrens*.
- 4. Stems not conspicuously 4-winged (5)
- 5(4). Sepals 4; seeds in several series in each locule of the capsule, free 2. *L. octovalvis*.
- 5. Sepals 5 (rarely 6); seeds in 1 series in each locule of the capsule, surrounded by woody endocarp at maturity (6)
- 6(5). Seeds each surrounded by a horseshoe-shaped (hippocrepiform) piece of endocarp, readily falling free 3. *L. leptocarpa*.
- 6. Seeds fused in large masses of endocarp, the entire capsule tough and woody (7)
- 7(6). Flowering stems erect; plants covered with long spreading pubescence; petals 12-23 mm. long 5. *L. uruguayensis*.
- 7. Flowering stems usually decumbent; plants subglabrous; petals 7-14 (-24) mm. long 4. *L. peploides*.
- 8(3). Capsule nearly globose, opening by a terminal pore; roots fascicled; stolons lacking (9)
- 8. Capsules variable in shape, irregularly dehiscent; roots not fascicled or if so the capsule not globose; plants with creeping stolons (10)
- 9(8). Plants hirsute; leaves sessile 6. *L. hirtella*.
- 9. Plants glabrous to puberulent; leaves petiolate 7. *L. alternifolia*.
- 10(8). Petals present 8. *L. linearis*.
- 10. Petals absent (11)
- 11(10). Plants conspicuously pilose 9. *L. pilosa*.
- 11. Plants glabrous to very minutely strigulose 10. *L. glandulosa*.

1. *Ludwigia decurrens* Walt. PRIMROSE-WILLOW. Subglabrous erect herb to 2 m. tall, freely branched, the stems 4-winged; leaves lanceolate to elliptical, 2-12 (-16) cm. long, 2-35 mm. wide, subsessile; sepals 4, 7-10 mm. long; petals 8-12 mm. long; stamens 8; disk not elevated, with a sunken white-hairy nectary surrounding the base of each epipetalous stamen; capsule 1-2 cm. long, 3-4.5 mm. thick, sharply 4-angled, irregularly and readily loculicidal, the pedicel 0-1 cm. long; seeds in several series in each locule, free, 0.3-0.4 mm. long, the raphe about one fifth the diameter of the body; $n = 8$. *Jussiaea decurrens* (Walt.) DC. Swamps and wet places, e. Tex., June-Oct.; s.e. U.S. to e. Tex and scattered to n. Arg.

2. *Ludwigia octovalvis* (Jacq.) Raven subsp. *octovalvis*. Subglabrous to strigulose usually well-branched weedy herb to 1 m. tall or more; leaves lanceolate or narrowly lanceolate to narrowly ovate, 3-14.5 cm. long, 4-40 mm. wide, the petiole 0-1 cm. long; sepals 4, (6-) 8-13 mm. long; petals 5-16 mm. long; stamens 8; disk slightly elevated, with a white-hairy sunken nectary surrounding the base of each epipetalous stamen; capsule thin-walled, 17-45 mm. long, 2-8 mm. thick, readily and irregularly loculicidal, the pedicel 0-1 cm. long; seeds in several indistinct rows in each locule, 0.6-0.75 mm. long, free, each with an inflated raphe equal in size to the body of the seed; $n = 16, 24$. *Jussiaea suffruticosa* L. [incl. var. *octofila* (DC.) Munz. and var. *ligustrifolia* (H.B.K.) Griseb.] In swamps and other wet places, widespread through s. half of the state, July-Oct.; warmer regions of the world.

The presence in Texas of the closely related *L. bonariensis* (Mich.) Hara ($n = 8$) requires confirmation. The ovary of this species at anthesis about equals the sepals instead of exceeding them, the capsule is usually shorter than the pedicel instead of longer and the petals are 20-35 mm. long. The specimens upon which this species has been reported (as *Jussiaea bonariensis* Mich.) from Texas are inadequate for certain determination.

3. *Ludwigia leptocarpa* (Nutt.) Hara. Usually robust hairy plants to 15 dm. tall, freely branched; leaves broadly lanceolate, 3.5-18 cm. long, 1-4 cm. wide, the petiole 2-35 mm. long; sepals 5 (rarely 4, 6 or 7), 5.5-11 mm. long; petals 5-11 mm. long; stamens twice as many as the sepals; disk slightly elevated, with a depressed hairy nectary surrounding the base of each epipetalous stamen; capsule 1.5-5 cm. long, 2.5-4 mm. thick, slowly and irregularly loculicidal, the pedicel 2-20 mm. long; seeds in 1 series in each locule, horizontal, 1-1.2 mm. long, each loosely embedded in an easily detached horse-shoe-shaped (hippocrepiform) segment of firm endocarp 1-1.5 mm. thick and about 1 mm. high; $n = 16$. *Jussiaea leptocarpa* Nutt. Wet places, as along ditches, e. Tex., Aug.-Oct.; e. to Mo., Ga., n. Fla., s. to W.I., Peru and Arg.; trop. Afr.

4. *Ludwigia peploides* (H.B.K.) Raven subsp. *peploides*. VERDOLAGA DE AGUA. Subglabrous sprawling or floating herb with somewhat ascending flowering branches to 6 dm. long; leaves oblong to oblong-spatulate, 1-9 cm. long, 5-40 mm. wide, the petiole 2-40 mm. long; sepals 5, 4-12 mm. long; petals 7-14 (-24) mm. long; stamens 10; disk slightly elevated, with a depressed white-hairy nectary surrounding the base of each epipetalous stamen; capsule 1-4 cm. long, 3-4 mm. thick, very tardily and irregularly dehiscent, the pedicel 1-6 (-8) cm. long; seeds in 1 series in each locule, more or less vertical, 1.1-1.3 mm. long, each firmly embedded in a coherent cube of woody endocarp 1.2-1.5 mm. high, 1-1.2 mm. thick, the endocarp firmly fused to the capsule wall; $n = 8$. *Jussiaea repens* L. var. *glabrescens* O. Ktze. and var. *peploides* (H.B.K.) Griseb. Ponds and streams, e.-cen. and e. Tex., locally w. to the Trans-Pecos, Apr.-Oct.; throughout warmer portions of New World; the species as a whole also in n.e. Asia and temp. Austral. and introd. elsewhere.

5. *Ludwigia uruguayensis* (Camb.) Hara. Long hairy perennial herb with decumbent rooting and more or less erect ascending branches to 1 m. tall, the floating branches subglabrous; leaves spatulate to oblanceolate, 3-10 cm. long, 3-10 mm. wide, the petiole 1-5 (-25) mm. long; sepals 5 (rarely 6), 6-14 mm. long; petals 12-23 mm. long; stamens twice as many as the sepals; disk slightly elevated, with a depressed white-hairy nectary surrounding the base of each epipetalous stamen; capsule 13-25 mm. long, 3-4 mm. thick, very tardily and irregularly dehiscent, the pedicel 5-50 mm. long; seeds in 1 series in each locule, more or less vertical, 1-1.3 mm. long, each firmly embedded in a coherent cube of woody endocarp 1.2-1.5 mm. high, 1-1.2 mm. thick, the endocarp firmly fused to the capsule wall; $n = 24$. *Jussiaea uruguayensis* Camb. Wet places, as along ponds and ditches, scattered in s.e. Tex., June-Sept.; s.e. U.S. and scattered s. to n. Arg. and introd. elsewhere.

6. *Ludwigia hirtella* Raf. SPINDLE-ROOT. Erect hirsute herb with fascicled spindle-shaped roots, to 1 m. tall; leaves narrowly lanceolate or lanceolate, 1.5-6 cm. long, 3-18 mm. wide, essentially sessile; sepals 4, 7-10 mm. long; petals 10-15 mm. long; stamens 4; disk strongly elevated, a depressed white-ciliate nectary surrounding the base of each epipetalous stamen; capsule subglobose-cubical, 4-6 mm. long and thick, dehiscent by a terminal pore, the pedicel 4-8 mm. long; seeds in several indistinct rows in each locule, about 0.6 mm. long, free; $n = 8$. Rare along wet places in pine woods, e. Tex., June-Sept.; e. along Coastal Plain to Fla. and N.J.

7. *Ludwigia alternifolia* L. SEED-BOX, RATTLE-BOX. Erect subglabrous or puberulent herb with fascicled spindle-shaped roots, to 12 dm. tall; leaves lanceolate, 4-8 (-12) cm. long, 8-15 (-24) mm. wide, the petiole 3-7 (-10) mm. long; sepals 4, 7-10 mm. long; petals 8-10 mm. long; stamens 4; disk strongly elevated, a depressed white-ciliate nectary surrounding the base of each epipetalous stamen; capsule subglobose-cubical, 5-6 mm. long and thick, dehiscent by a terminal pore, the pedicel 3-5 mm. long; seeds in several indistinct rows in each locule, 0.6-0.7 mm. long, free; $n = 8$. Incl. var. *pubescens* Palm. & Steyerl. Occasional along ditches and in wet places, e. Tex., June-Aug.; Mass. and Ont. to n. Fla., e. Tex. and Ia.

8. *Ludwigia linearis* Walt. Glabrous to puberulent erect usually well-branched herb to 1 m. tall; leaves linear to narrowly elliptical, 2.5-6 cm. long, 1.5-5 mm. wide, subsessile;

sepals 4, 2.5-4 mm. long; petals 3.5-5 mm. long; stamens 4; disk elevated, glabrous, prominently 4-lobed, the lobes opposite the petals; capsule elongate-obpyramidal, 6-8 mm. long, irregularly loculicidal, sessile; seeds in several indistinct rows in each locule, about 0.6 mm. long, free; $n = 8$. Incl. var. *puberula* Engelm. & Gray. Occasional in wet places, especially in pine woods, s.e. Tex., June-Sept.; e. to n. Fla., Tenn. and N.J.

9. *Ludwigia pilosa* Walt. Pilose erect usually well-branched herb to 12 dm. tall; leaves linear to elliptical, 2-10 cm. long, 3-15 mm. wide, the petiole 1-5 (-15) mm. long; sepals 4, 4-5 mm. long; petals absent; stamens 4; disk elevated, glabrous, prominently 4-lobed, the lobes opposite the sepals; capsule cubic-globose, 3-4 mm. long and thick, irregularly loculicidal, sessile; seeds in several indistinct rows in each locule, about 0.5 mm. long, free; $n = 16$. Occasional in wet places, especially in pine woods, s.e. Tex., July-Oct.; e. along the Coastal Plain to n. Fla. and s. Va.

The general habit of the eastern linear-lanceolate to oblong leaved *L. sphaerocarpa* Ell., that reaches Louisiana, is similar to some plants referred here to *L. pilosa*. It may eventually be found in southeast Texas, and may be distinguished by its glabrous to minutely appressed-pubescent herbage and hypanthium, and its very short hypanthium bracteole (less than 2 mm. long) in contrast to the long bracteole (2.5-4.2 mm. long) of *L. pilosa*.

10. *Ludwigia glandulosa* Walt. CYLINDRIC-FRUITED LUDWIGIA. Glabrous or minutely strigulose erect well-branched herb to 1 m. tall; leaves lanceolate or elliptical, 1.5-10 cm. long, 4-20 mm. wide, the petiole 2-10 mm. long; sepals 4, 1-2 mm. long; petals absent; stamens 4; disk elevated, glabrous, prominently 4-lobed, the lobes opposite the petals; capsule subcylindric, 2-8 mm. long, 1.5-2 mm. thick, irregularly loculicidal, sessile; seeds in several indistinct rows in each locule, about 0.6-0.7 mm. long, free; $n = 16$. Incl. var. *Torreyi* Munz. Wet places, as along ditches and in swamps, e. Tex., June-Oct.; n. and e. to s. Ill., Va. and n. Fla.

11. *Ludwigia palustris* (L.) Ell. MARSH PURSLANE. Glabrous herb, creeping and rooting at the nodes, the stems to 5 dm. long; leaves broadly elliptical or subovate, 7-45 mm. long, 4-23 mm. wide, the petiole 3-12 mm. long; sepals 4, 1.4-2 mm. long; petals absent; stamens 4; disk elevated, glabrous, prominently 4-lobed, the lobes opposite the petals; capsule elongate-globose, (2-) 2.5-5 mm. long, 2-3 mm. thick, fairly readily and irregularly loculicidal, sessile; seeds in several indistinct rows in each locule, 0.6-0.9 mm. long, free; $n = 8$. Incl. var. *americana* (DC.) Fern. & Griseb. and var. *nana* Fern. & Griseb. Wet places as about ponds and along rivers; e. and s.-cen. Tex. to the Llano area and in the Davis Mts., June-Sept.; temp. N.A. except Rocky Mt. area to Col.; also in w. Euras., N. and S. Afr. and introd. elsewhere.

12. *Ludwigia repens* Forst. FLOATING OR CREEPING PRIMROSE-WILLOW, WATER PRIMROSE. Glabrous to puberulent herb, creeping and rooting at the nodes, the stems to 5 dm. long; leaves very narrowly elliptic to subrotund, 9-40 mm. long, 2-20 mm. wide, the petiole 3-25 mm. long; sepals 4, 2.4-4.2 mm. long; petals 4-5 mm. long, fugacious; stamens 4; disk elevated, glabrous, prominently 4-lobed, the lobes opposite the petals; capsule short-cylindrical, 3.3-7.5 mm. long, 1.9-4.5 mm. thick, tardily and irregularly dehiscent, the pedicel 0.3-1.5 mm. long; seeds in several indistinct rows in each locule, about 0.7 mm. long, free; $n = 24$. *L. natans* Ell. and var. *rotundata* (Griseb.) Fern. & Griseb. Scattered in wet places as along streams and about ponds, n. of the Rio Grande Plains but very rare in n. Tex. and the Panhandle, July-Sept.; N.C. to Fla., Tex. and Okla., s. to cen. Mex. and W.I.; widely grown as an aquarium plant.

7. EPILOBIUM L. WILLOW-HERB

Perennial herbs of wet places, often flowering the first year; leaves opposite below, alternate above, denticulate or serrate; stipules absent; flowers actinomorphic, 4-merous, borne in the axils of reduced upper leaves; hypanthium well-developed; sepals not persistent in fruit; petals white to pink; stamens 8; stigma subclavate, undivided; fruit an elongate loculicidally dehiscent capsule; seeds numerous, with a coma, strongly papillose.

About 215 species of temperate and cold regions, extending into the tropics in the mountains and world-wide.

- 1. Leaves narrowly lanceolate, rugulose-veiny, with 30 to 75 teeth on each margin; plant mostly 5-10 dm. tall; petals pink; coma cinnamon-colored 1. *E. coloratum*.
- 1. Leaves elliptic to narrowly ovate, faintly veined, usually with about 20 to 30 teeth on each margin; plant 1-4 dm. tall; petals white to very pale-pink; coma white 2. *E. ciliatum*.

1. *Epilobium coloratum* Biehler. Perennial herb with sessile basal rosettes, 5-10 dm. tall, usually well-branched above, minutely strigulose above (especially along elevated lines decurrent from the margins of the petioles); hypanthium about 0.5 mm. long; sepals 1.5-3 mm. long; petals pink, 3-5 mm. long; capsule 3-4.5 cm. long; seeds about 1.5 mm. long, the coma cinnamon-colored. Rare in wet places, Hemphill and Wheeler cos. (High Plains), July-Oct.; Que. to S.D., s. to Ga., Ark. and n. Tex.; also Hisp.

2. *Epilobium ciliatum* Raf. Perennial herb with sessile leafy basal rosettes, 1-4 dm. tall, simple to well-branched, minutely strigulose above (especially along elevated lines decurrent from the margins of the petioles); hypanthium about 1 mm. long; sepals about 2 mm. long; petals white to pale-pink, about 3 mm. long; capsule 4-6 cm. long; seeds 1-1.5 mm. long, the coma white. *E. adenocaulon* Hausskn. var. *perplexans* Trel. Scattered in wet places in the Trans-Pecos, May-Sept.; Nfld. to B.C., s. to N.E., Pa., Wisc., w. Tex. and Calif.

Circaea quadrisulcata (Maxim.) Franch. & Sav. var. *canadensis* (L.) Hara, the "enchanter's nightshade," has been reported from Texas but we have seen no specimens. This is a delicate plant that may be distinguished from all other species of Onagraceae found in Texas by having 2-merous flowers, fruit indehiscent and bristly, and leaves opposite. It usually occurs in rich moist woodlands, thickets and ravines, and flowers in summer. It should be looked for in northeast Texas.

FAM. 135. HALORAGACEAE R. BR. WATER-MILFOIL FAMILY

Aquatic or paludal plants with the inconspicuous symmetrical perfect or unisexual flowers sessile in the axils of leaves or bracts; calyx tube (hypanthium) adherent to the ovary that consists of 3 (or 4) united carpels; styles or sessile stigmas distinct; limb of the calyx obsolete or very short in perfect or pistillate flowers; petals small or none; stamens 1 to 8; fruit indehiscent, 3- or 4-celled, with a single anatropous seed suspended from the summit of each cell.

About 120 species in 6 genera, cosmopolitan. The name is sometimes misspelled "Haloragidaceae."

- 1. Flower parts in threes; leaves alternate, the emersed ones amply foliaceous 1. *Proserpinaca*, p. 1136.
- 1. Flower parts in fours; leaves whorled or rarely partly opposite or alternate, the emersed ones much-reduced and mostly bractlike (sometimes enlarged in *M. heterophyllum*) 2. *Myriophyllum*, p. 1137.

1. PROSERPINACA L. MERMAID-WEED

Low herbaceous perennials with simple or sparsely branched stems that are creeping and rooting at the rhizomatous base; leaves alternate, pinnately dissected or the upper ones lanceolate and serrate, those on the same plant uniform or of both extreme types and intermediate forms; flowers sessile and solitary in the leaf axils, perfect; calyx 3-parted; corolla wanting; stamens 3; pistil 3-angled, with 3 stigmas; fruit nutlike, 3-angled, 3-celled, 3-seeded.

Several species in North America.

- 1. Upper leaves lanceolate, serrate 1. *P. palustris*.
- 1. Upper leaves like the lower ones, pinnately divided ... 2. *P. pectinata*.

1. *Proserpinaca palustris* L. Plant repent and rooting along the stems at base; stems ascending or suberect, occasionally trailing up into shrubs, to 1 m. or more long, the base submersed, the summit becoming emersed; submersed leaves rufescent, sessile, finely pinnatifid, to 6 cm. long, with 8 to 14 linear-filiform divisions on each side, the divisions to 3 cm. long, commonly bearing minute black axillary spicules, the median portion linear and about 1 mm. wide; amphibious leaves petioled, pinnatisect, to 7 cm. long, lanceolate, with the lanceolate middle portion to 1 cm. broad; emersed leaves lanceolate to oblanceolate, to 85 mm. long and 15 mm. wide, serrate; flowers in leaf axils of only the serrate leaves, solitary or in clusters of 2 to 5, subtended by minute lanceolate serrate bracts; calyx tube 3-angled, its ovate to deltoid lobes obtuse to acute; petals rudimentary; fruit trigonous-urceolate or pyramidal. In shallow water, about springs, in ditches and along shores of streams and lakes in e. Tex., spring-summer; from e. Can., s. to Ga. and Tex.

Our plant belongs to var. *amblyogona* Fern., characterized by having the angles of the fruits rounded or nearly obsolete.

2. *Proserpinaca pectinata* Lam. Stem very slender, repent, with an ascending rufescent summit to 3 dm. high; leaves all deeply pinnatifid, ovate-elliptic in outline, to 25 mm. long, with a linear median portion about 1 mm. wide and 4 to 9 slender rather firm divisions (to 7.5 mm. long) on each side, sometimes bearing minute black spicules; flowers solitary or rarely in twos or threes in the middle and upper leaf axils; calyx lobes acuminate; fruit urceolate, with rounded or obtuse angles, 3-4 mm. long, 2-3 mm. broad. In peaty soils of swamps and savannahs and in shallow water, rare in s.e. Tex., spring-summer; mostly in the Coastal Plain from N.S. and s.w. Me., s. to Tenn., Fla. and Tex.

2. MYRIOPHYLLUM L.

WATER-MILFOIL

Perennial aquatics; stems mostly elongated; leaves usually whorled (in ours), the submersed ones pinnately parted into capillary divisions; flowers unisexual and perfect on the same plant, small, sessile, chiefly in the axils of the upper leaves or bracts, usually above water in summer, the uppermost ones staminate; calyx of the staminate flowers 4-parted, of the pistillate flowers 4-toothed; petals 4 or none; stamens 4 or 8; stigmas 4, recurved; fruit nutlike, 4-celled, deeply 4-lobed.

About 45 species, cosmopolitan.

1. Leaf whorls on middle and lower parts of stem mostly 1 cm. or more apart (2)
1. Leaf whorls on middle and lower parts of stem usually much less than 1 cm. apart (3)
- 2(1). Leaf divisions filiform, typically 6 mm. or more long; flowers borne in whorls on a slender terminal spike, mostly longer than the subtending bract 1. *M. spicatum*.
2. Leaf divisions stoutish, mostly less than 6 mm. long; flowers borne in clusters in the axils of leaves 2. *M. brasiliense*.
- 3(1). Floral bracts pinnately dissected or lobed 3. *M. verticillatum*.
3. Floral bracts entire or only toothed (4)
- 4(3). Leaves mostly all in definite whorls; submersed leaves with 5 to 10 capillary divisions on each side; bracteoles ovate to lanceolate, acuminate; carpels with 2 smoothish dorsal ridges 4. *M. heterophyllum*.
4. Leaves whorled, subverticillate, opposite or alternate on the same plant; submersed leaves with about 5 capillary divisions on each side; bracteoles obtusely triangular; carpels with 2 prominently tuberculate dorsal ridges 5. *M. pinnatum*.

1. *Myriophyllum spicatum* L. Stems simple or branched, purplish, becoming pinkish or whitish upon drying; leaves whorled, in threes or fours, to about 3 cm. long, broadly oval to elliptic in outline, with 6 to 11 capillary usually flaccid divisions on each side, the divisions to 2 cm. long; spikes almost naked, to 1 dm. long, with verticillate flowers, the lower flowers pistillate, the upper flowers staminate; bracts rarely equalling the fruit,

spatulate-obovate to oblong-cochleariform, the lower bracts serrate, the upper bracts entire; bracteoles ovate, entire, to 1 mm. long; petals oblong-obovate, concave, about 2.5 mm. long; anthers 8, oblong, to 1.8 mm. long; fruits subglobose, very slenderly 4-sulcate, 2.3-3 mm. long, the carpels rounded on the back and smooth or rugulose. In ponds, tanks, pools, lakes and quiet streams, often calcareous or somewhat brackish, mainly through cen. Tex. from e. to w., also in the Panhandle, Apr.-Sept.; from s.e. Lab. to Alas., s. to W.Va., Tex., Ariz. and s. Calif.

Our plants are usually referred to var. *exalbescens* (Fern.) Jeps. (*M. exalbescens* Fern.).

2. *Myriophyllum brasiliense* Camb. PARROT'S-FEATHER, WATER-FEATHER. Plants pallid or light-green, with the upper part emersed or trailing on mud or seepage and erect-ascending; stems simple or sparsely branched; leaves all whorled, oblong in outline, stiffish, 2-5 cm. long, puberulent when young, glabrous with age, dissected into 10 or more pectinately arranged linear-filiform divisions on each side, the upper divisions 3-6 mm. long, the lower divisions much-reduced; bracteoles filiform, 2- or 3-cleft; flowers unisexual, in the axils of the leaves; pistillate flowers about 1.5 mm. long, conspicuous as a tuft of white or pinkish plumose stigma-lobes; staminate flowers not seen; fruit 1.5-2 mm. long, minutely glandular. *M. proserpinacoides* Gill. Widely scattered in ponds, ditches, streams and on seepage slopes, mainly on the Edwards Plateau and in e. Tex., Mar.-May; nat. to S.A., tending to escape from cult. and persistent in s. U.S.

3. *Myriophyllum verticillatum* L. Stems simple or with few elongate branches to 25 dm. long, in autumn producing crowded winter-buds 1-2 cm. long; leaves in fours and fives; submersed leaves to 45 mm. long, with 9 to 13 opposite or alternate pairs of capillary flaccid divisions to 28 mm. long; emersed leaves and bracts smaller and with coarser divisions or merely pectinate-pinnate; flowers in whorls of 4 to 6, perfect or the lower ones pistillate and the upper staminate; bracteoles palmately 7-lobed, about 0.5 mm. long; petals (merely rudiments in pistillate flowers) spoon-shaped, obtuse, about 2.5 mm. long; anthers 8 or 4, about 2 mm. long; fruit subglobose, 2-2.5 mm. long, deeply 4-furrowed, the brown smooth or somewhat tuberculate (in ours) carpels rounded on back. In lakes in n.e. Tex., Apr.-June; a highly variable circumpolar species that occurs in N.A. from Nfld. to B.C., s. to Ut. and n.e. Tex.

Plants referred here are typical in regard to leaves and floral bracts, but their fruits are atypical in that they closely resemble those of *M. heterophyllum*. These plants may eventually be found to represent a completely new entity.

4. *Myriophyllum heterophyllum* Michx. Stems rather stout; leaves whorled, in fours to sixes, the submersed pinnate leaves 2-5 cm. long and with 7 to 10 flaccid capillary divisions on each side, the divisions to about 2 cm. long, the amphibious leaves pinnatisect; emersed leaves and bracts firm, lanceolate or spatulate-lanceolate to elliptic, entire or serrate, to 3 cm. long and 1 cm. wide; spikes emersed, to 4 dm. long, usually much shorter; flowers in whorls of 4 to 6, perfect or with the lower pistillate and the upper staminate; bracteoles ovate, acuminate, serrate, 1-1.3 mm. long, 0.5-0.7 mm. wide; petals (of staminate flowers) acutish, 1.5-3 mm. long; anthers 4, to 2.5 mm. long; fruit subglobose, 1-1.5 mm. long and wide, minutely papillose, with the carpels 2-ridged on the back but rounded on the sides and prominently beaked. In ponds, lakes and streams, mainly on the Edwards Plateau and in s.e. Tex., Apr.-Aug.; from Fla. to Tex. and N.M., n. to N.D., Ont. and s.w. Que.

A large-bracted form of this species occurs in southeast Texas.

5. *Myriophyllum pinnatum* (Walt.) B.S.P. GREEN PARROT'S-FEATHER. Plant variable, either submersed or essentially terrestrial; stems rooting in mud and freely branched or becoming much-elongated when growing in water; leaves in whorls of 3 to 5 or subverticillate or commonly scattered, to about 3 cm. long, the submersed leaves with about 5 short remote capillary divisions on each side; emersed leaves linear to oblanceolate, pectinate or sharply serrate, to 2 cm. long; flowers in the axils of the emersed leaves, perfect or unisexual; bracteoles bluntly triangular, about 1 mm. long; petals purplish, 1.5-2 mm. long, rounded above, with a short claw; anthers 4, about 1 mm. long; fruit pale, ovoid, 1.3-1.8 mm. long, the carpels with flat sides and 2 tuberculate dorsal ridges. *M. scabratum* Michx. In swamp forests, on muddy shores or in shallow waters in e. and s.e. Tex., Mar.-June; from Fla. to Tex., n. to s. N.E., W.Va., Ky., Ill. and Ia.

FAM. 136. ARALIACEAE JUSS.

GINSENG FAMILY

Herbs, shrubs or trees with usually alternate compound or decomposed leaves and stipules; flowers regular or nearly so, epigynous, usually perfect, 4- or 5-merous; calyx small, its limb truncate to denticulate; petals usually distinct, not inflexed, deciduous at maturity; stamens inserted on disk within the calyx, alternate with the petals; anthers short, longitudinally dehiscent; ovary inferior, several-celled, with a solitary anatropous ovule suspended in each cell; styles as many as the cells of the ovary, distinct or more or less connate; fruit a 5-celled berry.

About 700 species in about 55 genera, most abundant in tropics but widespread. Especially in east Texas, *Hedera helix* L. (English ivy), the cultivated root-climber, persists about old homesteads and occasionally spreads to woodlands and glades. Its leaves are dimorphic—those on the climbing shoots lobed and sometimes mosaic, those of the fertile, freely projecting shoots unlobed.

I. ARALIA L.

Plants perennial, often with spicy-aromatic roots; flowers small, regular, polygamous, in umbels that form terminal panicles; petals and stamens each 5; ovary 5-celled; fruit a 5-seeded berry, tipped by the persistent style.

About 35 species in Asia and North America.

1. Trees or sometimes shrubs; stem and leaf stalks prickly; umbels numerous, in a large broad panicle 1. *A. spinosa*.
1. Herbs without prickles; umbels in a racemose panicle .. 2. *A. racemosa*.

1. *Aralia spinosa* L. HERCULES'-CLUB, DEVIL'S-WALKING-STICK, ANGELICA-TREE. Shrub or tree to 12 m. tall or more, the stout trunk to 3 dm. in diameter; leaves to 1 m. long or more; leaflets firm, ovate to broadly elliptic, broadly rounded to cuneate at base, acute to acuminate at apex, to 1 dm. long and 6 cm. wide, serrulate to serrate, pale on lower surface; umbels in a large compound panicle; peduncles and pedicels copiously pilose; fruit black, about 6 mm. in diameter. In woodlands, mostly along streams, in e. Tex., May-June; from Fla. to Tex., n. to N.J., Pa., w. N.Y., O., Ind., s. Ill. and Ia.

2. *Aralia racemosa* L. AMERICAN SPIKENARD. Herb to 2 m. tall or occasionally more, prickleless, widely branched; leaves wide-spreading, to about 8 dm. long; leaflets ovate to ovate-elliptic, obliquely cordate at base, long-acuminate at apex, to 17 cm. long and 12 cm. wide, usually much smaller, doubly serrate, slightly downy; umbels racemose-paniculate; peduncles and pedicels copiously puberulent; styles united at base; fruit dark-purple, about 5 mm. in diameter. *A. bicrenata* Woot. & Standl. In rich woods and thickets in high mts. of the Trans-Pecos (collected once in fruit at base of "dome" on top of Mt. Livermore, Davis Mts., Sept. 21, 1935, L. C. Hinckley 405); from Que. w. to Man., s. to Ga., Tex., Ariz. and n. Mex.

FAM. 137. UMBELLIFERAE JUSS.¹⁴⁰

PARSLEY FAMILY

Primarily herbaceous plants, acaulescent or caulescent, annual, biennial or perennial, with commonly hollow stems; leaves alternate or rarely opposite or basal, compound or sometimes simple, usually much-incised or -divided, with usually sheathing petioles; flowers small, regular, in simple or compound umbels, or the umbels sometimes proliferous or capitate; rays sometimes subtended by bracts forming an involucre; umbellets usually subtended by bractlets forming an involucre; calyx tube wholly adnate to the ovary; calyx teeth usually obsolete or small; petals 5, usually with an inflexed tip; stamens 5, inserted on an epigynous disk; ovary inferior, bilocular; styles 2, sometimes swollen at the base, forming a stylopodium; fruit consisting of two mericarps united by their faces

¹⁴⁰ Contributed by Mildred E. Mathias and Lincoln Constance; cf. their earlier treatment in C. L. Lundell, *Flora of Texas* III:263-329. 1951.

(commissure), compressed or flattened dorsally (parallel to the commissure), laterally (at right angles to the commissure) or terete, each mericarp with 5 primary ribs, one down the back (dorsal rib), two on the edges near the commissure (lateral ribs) and two between the dorsal and lateral ribs (intermediate ribs) and rarely with secondary ribs, the ribs filiform to broadly winged and thin or corky; oil tubes obsolete or present in the intervals (spaces between the ribs) and on the commissural surface, rarely also in the pericarp; mericarps 1-seeded, splitting apart at maturity, usually suspended from the summit of a slender prolongation of the axis (carpophore).

A cosmopolitan family of worldwide distribution consisting of at least 200 genera and perhaps 3,000 species.

1. Flowers and fruits borne in compound umbels or bracteate heads (2)
1. Flowers and fruits borne in simple noncapitate umbels; leaves small and relatively simple (43)
- 2(1). Flowers and fruits (or some of them) pedicellate; fruits more or less evidently ribbed; calyx minute or obsolete (3)
2. Flowers and fruits sessile or subsessile in dense bracteate heads or headlike umbellets; fruits with obsolete ribs, crowned by the prominent and persistent calyx and densely beset with scales, tubercles or uncinatate prickles (42)
- 3(2). Fruits terete to somewhat compressed laterally, the ribs not prominently winged (4)
3. Fruits strongly flattened dorsally, some or all of the ribs broadly winged (34)
- 4(3). Fruits merely bristly-pubescent to glabrous (5)
4. Fruits armed with uncinatate or barbed bristles or prickles, or tuberculate, papillate or callous-toothed (31)
- 5(4). Fruits oblong to ellipsoid, less than twice as broad as long (6)
5. Fruits linear to oblong, more than twice as long as broad (26)
- 6(5). Petals subequal; pericarp corky or chartaceous, not hardened; oil tubes evident (7)
6. Outer petals usually radiant (cf. also *Sium*); pericarp very hard; oil tubes lacking (25)
- 7(6). Pericarp not corky-thickened; fruit ribs filiform to prominent, never corky (8)
7. Pericarp of some or all of the fruit ribs corky-thickened (18)
- 8(7). Perennials; leaflets not pinnately dissected; stylopodium lacking (9)
8. Annuals or biennials; leaflets usually pinnately dissected; stylopodium depressed-conic to conic (11)
- 9(8). Plants acaulescent; seed face deeply sulcate 1. *Tauschia*, p. 1143.
9. Plants caulescent, branching; seed face plane or slightly concave (10)
- 10(9). Leaflets serrate or dentate; involucre present; central flower of each umbellet fertile, sessile or subsessile 2. *Zizia*, p. 1143.
10. Leaflets entire; involucre lacking; central flower of each umbellet sterile, pedicellate 3. *Taenidia*, p. 1143.
- 11(8). Leaves entire, parallel-veined 14. *Bupleurum*, p. 1149.
11. Leaves pinnate to decompose, pinnately veined (12)
- 12(11). Involucre present (13)
12. Involucre lacking (14)
- 13(12). Fruit ribs plane; oil tubes solitary in the intervals; stems not spotted 15. *Ammi*, p. 1150.
13. Fruit ribs undulate, crenate; oil tubes very small, numerous, irregular; stems variously spotted 16. *Conium*, p. 1150.
- 14(12). Involucre lacking (cf. also *Ammoselinum* and *Spermolepis*) (15)
14. Involucre present (16)

- 15(14). Flowers yellow; carpophore divided to the base ..17. *Foeniculum*, p. 1151.
- 15. Flowers white; carpophore bifid or shallowly cleft ...18. *Apium*, p. 1151.
- 16(14). Slender erect biennials; pedicels numerous, subequal; flowers yellow or greenish-yellow, the petals with a narrower inflexed apex; carpophore divided to the middle or the base19. *Petroselinum*, p. 1152.
- 16. Low diffuse annuals; pedicels few, unequal; flowers white, the petals obtuse and plane; carpophore divided only at the apex (17)
- 17(16). Fruit ribs filiform, rounded, subequally spaced; plants glabrous27. *Spermolepis*, p. 1155.
- 17. Fruit ribs acute, the lateral of the two mericarps contiguous and appearing to form a single rib; plants roughened26. *Ammoselinum*, p. 1155.
- 18(7). Perennials; pericarp or at least some of the dorsal as well as the lateral fruit ribs corky-thickened (19)
- 18. Annuals; only the lateral fruit ribs corky-thickened (22)
- 19(18). Plants acaulescent or with few stem leaves, growing in dry rocky places in the mountains; flowers yellow; pedicels mostly less than 3 mm. long; fruit oblong, the ribs corky-winged 4. *Aletes*, p. 1144.
- 19. Plants caulescent, growing in wet places (swamps, marshes, along streams); flowers white; pedicels 2-15 mm. long; fruit orbicular to suborbicular, about as long as broad, the ribs not winged (20)
- 20(19). Fruit ribs obscure in the corky-thickened pericarp; plants stoloniferous 7. *Berula*, p. 1146.
- 20. Fruit ribs prominent, corky-thickened; plants not stoloniferous (21)
- 21(20). Involucre prominent; rays few; fruit ribs subequal in cross section 5. *Sium*, p. 1144.
- 21. Involucre inconspicuous or lacking; rays usually numerous; fruit ribs unequal in cross section 6. *Cicuta*, p. 1145.
- 22(18). Ultimate leaf divisions laciniate; bracts and bractlets equaling or exceeding the rays and pedicels, respectively; petal apex bilobed; carpophore divided to the base10. *Daucosma*, p. 1147.
- 22. Ultimate leaf divisions or leaves entire; bracts and bractlets shorter than the rays and pedicels, respectively; petal apex entire; carpophore bifid or divided about to the middle (23)
- 23(22). Leaves decompose with filiform divisions11. *Ptilimnium*, p. 1147.
- 23. Leaves entire, palmately parted or pinnate, with narrow elongated divisions (24)
- 24(23). Fruit prominently beaked; cauline leaves palmately parted; petals with a narrower inflexed apex12. *Cynosciadium*, p. 1148.
- 24. Fruit rounded at apex; leaves entire or pinnate; petal apex not inflexed13. *Limnosciadium*, p. 1148.
- 25(6). Basal leaves ternate-pinnately decompose, their divisions filiform; fruit conspicuously constricted to a narrow commissure, the mericarps separating readily .. 8. *Bifora*, p. 1146.
- 25. Basal leaves pinnately dissected, their divisions flabelliform; fruit not at all constricted at the commissure, the mericarps not separating readily 9. *Coriandrum*, p. 1146.
- 26(5). Fruits without secondary ribs (27)
- 26. Fruits with prominent corky or bristly secondary ribs (30)
- 27(26). Involucel lacking or inconspicuous; carpophore divided to the base; seed face plane21. *Cryptotaenia*, p. 1153.
- 27. Involucel conspicuous; carpophore bifid or 2-cleft above the middle; seed face sulcate (28)

- 28(27). Bractlets lobed or dissected; fruits with a long differentiated beak 23. *Scandix*, p. 1154.
28. Bractlets entire; fruits obtuse, acute or shortly beaked (29)
- 29(28). Annuals; fruits 4-8 mm. long, obtuse at base 20. *Chaerophyllum*, p. 1152.
29. Perennials; fruits 10-20 mm. long, acute or caudate at base 22. *Osmorhiza*, p. 1153.
- 30(26). Petals subequal; fruits glabrous, the primary ribs obscure; pedicels 1 mm. long or less 24. *Trepocarpus*, p. 1154.
30. Outer petals radiant; fruits setulose and bristly, the primary ribs filiform; pedicels 2-8 mm. long 25. *Cuminum*, p. 1154.
- 31(4). Mericarps flattened dorsally; secondary ribs prominently winged and armed with barbed or glochidiate prickles 29. *Daucus*, p. 1157.
31. Mericarps compressed laterally or terete; secondary ribs lacking or hidden by the prickles or tubercles occupying the intervals (32)
- 32(31). Fruit intervals beset with coarse prickles or tubercles, the lateral primary ribs displaced onto the commissure; petals with a narrow inflexed apex 28. *Torilis*, p. 1156.
32. Fruits finely tuberculate, papillate or callous-toothed; petals without an inflexed apex (33)
- 33(32). Fruit ribs filiform, rounded, subequally spaced; plants glabrous 27. *Spermolepis*, p. 1155.
33. Fruit ribs acute, the lateral of the two mericarps contiguous and appearing to form a single broad rib; plants roughened 26. *Ammoselinum*, p. 1155.
- 34(3). Lateral ribs and one or more of the dorsal broadly winged; plants usually acaulescent or subcaulescent, perennial (35)
34. Lateral ribs broadly winged, the dorsal very narrowly winged to obsolete (36)
- 35(34). Peduncles scaberulous at the summit; calyx teeth evident; seed face plane; plants caulescent or subcaulescent 31. *Pseudocymopterus*, p. 1160.
35. Peduncles glabrous; calyx teeth obsolete or inconspicuous; seed face concave to sulcate; plants acaulescent 30. *Cymopterus*, p. 1158.
- 36(34). Perennials or biennials (doubtful cases should be keyed under both alternatives) (37)
36. Annuals (40)
- 37(36). Plants from fascicled tubers; flowers white; stylopodium conical; lateral fruit wings nerved dorsally at the inner margin, the fruit thus appearing 5-ribbed 32. *Oxypolis*, p. 1160.
37. Plants from taproots; flowers yellow; stylopodium depressed or lacking; dorsal ribs of the fruit 3 (38)
- 38(37). Plants low, acaulescent; bractlets connate above the middle 35. *Lomatium*, p. 1162.
38. Plants tall, caulescent, branching; bractlets distinct or lacking (39)
- 39(38). Involucel present; lateral fruit wings corky-thickened; calyx teeth evident; stylopodium lacking 33. *Polytaenia*, p. 1161.
39. Involucel usually lacking; lateral fruit wings thin; calyx teeth obsolete; stylopodium present 34. *Pastinaca*, p. 1162.
- 40(36). Plants scaberulous; bracts and bractlets prominent, 3-cleft or ternate, reflexed .. 36. *Eurytaenia*, p. 1162.
40. Plants glabrous and glaucous; bracts and bractlets lacking or inconspicuous, entire, not prominently reflexed (41)
- 41(40). Leaves pinnately dissected, with filiform divisions; flowers yellow; lateral fruit wings thin 37. *Anethum*, p. 1163.
41. Leaves entire or palmately divided, with linear to linear-lanceolate divisions; flowers white; lateral fruit wings thick, corky 12. *Cynosciadium*, p. 1148.

- 42(2). Flowers in definite headlike umbellets arranged in irregular umbels; fruits with uncinat prickles38. *Sanicula*, p. 1163.
42. Flowers subtended by bractlets in dense bracteate heads; fruits scaly or tuberculate39. *Eryngium*, p. 1165.
- 43(1). Plants stellate-pubescent; leaves stipulate42. *Bowlesia*, p. 1169.
43. Plants glabrous or pubescent with simple trichomes; leaves exstipulate (44)
- 44(43). Involucre of 2 conspicuous bracts; fruit with 3 primary and 2 reticulated secondary dorsal ribs; petioles sheathing40. *Centella*, p. 1168.
44. Involucre multibracteate, inconspicuous; fruit without secondary ribs; petioles not sheathing41. *Hydrocotyle*, p. 1168.

1. TAUSCHIA SCHLECHT.

A genus of about 20 species of the highlands of Mexico and northern South America, and western United States.

1. *Tauschia texana* Gray. Acaulescent perennial from a taproot, 1-4 dm. high, glabrous throughout; leaves oblong, to 15 cm. long and 4 cm. wide, pinnate; leaflets sessile to petiolulate, ovate, distinct, the larger ones pinnately parted or lobed, the divisions cuneate; inflorescence of compound umbels; peduncles 1-4 dm. long; involucre lacking or of a single foliaceous bract; involucre of several linear to lanceolate connate bractlets, shorter than the flowers; fertile rays 5 to 8, unequal, 5-25 mm. long; flowers yellow, with pedicels 1-2 mm. long; calyx teeth minute; fruit oval, 3-4 mm. long, 2-3 mm. broad, slightly compressed laterally, glabrous, the ribs filiform; oil tubes 3 or 4 in the intervals and 4 on the commissure; seed face deeply sulcate. *Musenopsis texana* (Gray) Coult. & Rose. In alluvial thickets and wet woods in s. part of Blackland Prairies and in coastal region in Tex., Feb.-June; endemic.

2. ZIZIA KOCH

A genus of about 4 species, primarily of eastern United States and adjacent Canada, but extending to the Pacific Northwest.

1. *Zizia aurea* (L.) Koch. GOLDEN ALEXANDERS. Erect caulescent usually branching perennial from fascicled roots, 4-8 dm. high; basal leaves petiolate, ovate to orbicular, to 1 dm. long and 12 cm. wide, biternate or the middle leaflet pinnatifid; leaflets ovate to lanceolate, distinct, sharply serrate; cauline leaves like the basal, becoming narrowly lanceolate and confluent upwards; inflorescences of compound umbels; peduncles 5-15 cm. long; involucre lacking; involucre of a few inconspicuous linear acute bractlets 1-3 mm. long, shorter than or equaling the pedicels; rays 10 to 15, spreading-ascending, unequal, 1-3.5 cm. long; pedicels 2-3 mm. long; the central flower of each umbellet sessile or subsessile; flowers yellow; calyx teeth prominent; stylopodium lacking; fruit oblong-ovoid, 2-4 mm. long, 1.5-2 mm. broad, compressed laterally, the ribs filiform; oil tubes solitary in the intervals and 2 on the commissure; seed face slightly concave. In sandy woodlands and sandy-clay floodplains in the e. third of Tex., Apr.-Aug.; from e. Can., s. to Fla., w. to Sask., Mont. and Tex.

3. TAENIDIA DRUDE

A monotypic genus of the eastern and central United States and adjacent Canada.

1. *Taenidia integerrima* (L.) Drude. YELLOW PIMPERNEL. Plant perennial from taproots, erect, 3-8.5 dm. high, the slender stems branching and purplish toward the base; basal leaves ovate to obovate, 2- or 3-ternate or -pinnate, to 9 cm. long and wide; leaflets sessile, ovate to lanceolate, rounded to acute and shortly mucronulate at the apex, slightly decurrent to rounded at the base; cauline leaves like the basal, with wholly sheathing petioles; peduncles terminal and axillary, to 20 cm. long; umbels compound; involucre and involucre lacking; rays 15 to 20, 15-95 mm. long, spreading to ascending, unequal,

the central rays sterile and half the length of the fertile; flowers yellow, the calyx teeth obsolete, the stylopodium lacking; umbellets about 35-flowered, the central flowers sterile and short-pedicellate; fertile pedicels 7-12 mm. long; carpophore divided to the base; fruit oblong-oval, compressed laterally, glabrous, the filiform ribs unwinged; oil tubes several in the intervals and 4 on the commissure; seed face plane, 3-4 mm. long, 2-3 mm. broad. In rocky open woods, lowland woods and on bluffs in e. Tex., May-June; from e. Can., s. to Ga., w. to Minn., Kan., Ark. and Tex.

4. ALETES COULT. & ROSE

Plants low, caespitose, acaulescent or with few stem leaves, herbaceous, perennial from slender to stout elongated branching roots; leaves petiolate, pinnate or bipinnate to ternately decomposed, the short leaflets orbicular to filiform, distinct or confluent and often lobed and spinulose-dentate; inflorescence of compound umbels, the peduncles terminal; involucre usually lacking; involucrel subdimidiate, of connate or free bractlets; rays few to rather numerous, spreading to reflexed, the short pedicels spreading; flowers yellow, the deltoid-ovate calyx teeth usually conspicuous, the stylopodium lacking; carpophore divided to the base; fruit oblong to ovoid-oblong, slightly compressed laterally or subterete, glabrous, the ribs subequal, prominent and corky-winged or obscure; oil tubes solitary in the intervals and 2 on the commissure, the seed face plane or concave.

A genus of 6 species, chiefly of southwestern United States.

1. Leaves 1- or 2-pinnate; leaflets lanceolate to orbicular . . . 1. *A. acaulis*.
1. Leaves ternately decomposed; leaflets filiform 2. *A. filifolius*.

1. *Aletes acaulis* (Torr.) Coult. & Rose. Plant acaulescent, 5-35 cm. high; leaves petiolate, oblong, to 1 dm. long and 4 cm. wide, 1- or 2-pinnate; leaflets lanceolate to orbicular, acute, confluent, pinnately lobed and spinulose-dentate, 4-10 mm. long, 5-15 mm. wide, sometimes puberulent on the veins and ciliate; peduncles 5-27 cm. long, longer than the leaves, occasionally puberulent at the base of the umbel; bractlets lanceolate to linear, acute, 2-3 mm. long, membranaceous and sometimes ciliate, connate at the base; rays 8 to 15, subequal, 5-30 mm. long, spreading to reflexed, sometimes puberulent; pedicels 1-2 mm. long; fruit oblong, 4-7 mm. long, about 2 mm. broad, the 2 or 3 dorsal and the lateral ribs corky-winged, the wings obtuse; an accessory oil tube in the apex of each rib. In rocky ravines and canyons, and on cliffs, above 5,000 ft. alt. in the mts. of the Trans-Pecos, Apr.-Aug.; in the Rocky Mts. of Colo. and N.M., s. to Tex., Ariz. and Chih.

2. *Aletes filifolius* Math., Const. & Theobald. Plant 2-4 dm. tall, caespitose from a branching woody root crowned with old leaf sheaths, acaulescent or with 1 or 2 stem leaves; leaves petiolate, broadly ovate; blades 2.5-20 cm. long, 2.5-14 cm. broad, ternately pinnately decomposed, the filiform ultimate segments 5-56 mm. long and 1-2 mm. broad; peduncles 7-38 cm. long, longer than the leaves, scaberulent at the base of the umbel; bractlets of involucrel linear to lanceolate, 2-5 mm. long, free to slightly connate at base, rarely reduced to one; rays 4 to 21, 6-20 mm. long, spreading-ascending; pedicels 1.5-5 mm. long; fruits oblong to ovoid-oblong, 2.4-8 mm. long, 1.8-4 mm. broad, the dorsal and lateral ribs prominent and corky-winged; wings pale-yellow to white, rarely inconspicuous; oil tubes large. Usually in rocky places in mts. of the Trans-Pecos, May-Aug.; endemic.

5. SIUM L. WATER-PARSNIP

A chiefly circumboreal genus, containing perhaps a dozen species.

1. *Sium suave* Walt. Plant stout, perennial, 6-12 dm. high, the corrugated branching stems arising from fusiform fascicled roots; leaves oblong to ovate, to 25 cm. long and 18 cm. wide, pinnate or rarely simple and serrate and incised, the submerged leaves usually decomposed; leaflets lanceolate to linear, 1-4 cm. long, 3-15 mm. wide, distinct, remote, the lower frequently obsolete, finely to coarsely serrate or incised; peduncles stout, 4-10 cm. long; involucre of 6 to 10 lanceolate or linear bracts 3-15 mm. long that

are acute, entire or incised, unequal and reflexed; involucre of 4 to 8 linear-lanceolate bractlets 1-3 mm. long, acute, entire; rays 10 to 20, slender, subequal, 1.5-3 cm. long; pedicels 3-5 mm. long; flowers white; calyx teeth minute, the stylopodium usually depressed; the halves of the carpophore adnate to the mericarps; fruit oval to orbicular, 2-3 mm. long, 2-2.5 mm. broad, slightly compressed laterally and constricted at the commissure, the ribs prominent, subequal, corky; oil tubes 1 to 3 in the intervals and 2 to 6 on the commissure, the seed face plane; a prominent group of strengthening cells in the apex of each rib. *Sium cicutaefolium* Schrank. In swamps and marshes and other wet places in s.-cen. Tex., May-Sept.; from Nfld., s. to S.C., w. to B.C. and Calif.

This species, which superficially resembles the deadly poisonous *Cicuta maculata*, may be distinguished from that species by its simply pinnate leaves and corrugated stems.

6. CICUTA L. WATER-HEMLOCK

Plants stout or slender, erect, caulescent, branching, herbaceous, perennial from a tuberous base bearing fibrous to fleshy-tuberous roots; leaves 1- to 3-pinnate or ternate-pinnate, the leaflets serrate to incised; inflorescence of compound umbels, the peduncles terminal and lateral, exceeding the leaves; involucre usually lacking; involucre of several narrow bractlets or rarely lacking; rays numerous, slender, spreading-ascending, the slender pedicels spreading; flowers white or greenish, the calyx teeth evident, the stylopodium depressed or low-conic; carpophore divided to the base, deciduous; fruit oval or ovoid to orbicular or ellipsoid, compressed laterally and constricted at the commissure or not constricted, the usually prominent ribs obtuse and corky; oil tubes solitary in the intervals and 2 on the commissure, the seed face plane to slightly concave.

A circumboreal genus of about 8 species, one Eurasian, the others American. These plants, abundant in wet places, are notable for being *virulently poisonous*.

- 1. Fruits constricted at the commissure, the lateral ribs about equaling the dorsals in surface display; oil tubes very large; seed conspicuously oily, evidently channeled under the tubes1. *C. mexicana*.
- 1. Fruits not constricted at the commissure, the lateral ribs much broader than the dorsals in surface display; oil tubes only moderately large; seed not conspicuously oily, scarcely sulcate under the tubes2. *C. maculata*.

1. *Cicuta mexicana* Coult. & Rose. Plant stout, from a usually erect tuberous base bearing fleshy-tuberous roots, 9-24 dm. high; leaves ovate-deltoid, to 35 cm. long, ternate-pinnate or 2-pinnate; leaflets oblong-lanceolate, 4-10 cm. long, 1.5-4 cm. wide, finely to coarsely serrate, thick and strongly reticulate; peduncles 5-9 cm. long; involucre of 1 to several narrow bracts or lacking; involucre of several lanceolate to linear acute scarious-margined bractlets 2-5 mm. long, shorter than or equaling the flowers; rays very unequal, 2-8 cm. long; pedicels 3-15 mm. long; fruit orbicular or nearly so, 2-3 mm. long, constricted at the commissure, the low ribs broad and corky, subequal in surface display, broader than the intervals, the lateral ribs of the two carpels separated by an interval; oil tubes large; seed very oily, deeply sulcate under the tubes, the face plane or concave. *Cicuta Curtissii* Coult. & Rose. In swamps and other wet places in e. third of Tex. and along the coast, May-Oct.; from Middle Atl. U.S., s. to the Isthmus of Tehuantepec, Mex.

2. *Cicuta maculata* L. SPOTTED COWBANE, BEAVER-POISON. Plant stout, from a usually erect tuberous base bearing fleshy or fleshy-tuberous roots as well as often some fibrous roots above (all of which are deadly poisonous to man and animals), 6-18 dm. high; leaves ovate, to 3 dm. long and 26 cm. wide, 2- to 3-pinnate; leaflets lanceolate, acute to acuminate, 2-12 cm. long, 5-30 mm. wide, sharply and coarsely serrate or incised; peduncles 2-10 cm. long; involucre of a few narrow bracts or lacking; involucre of several linear to lanceolate acute to acuminate scarious-margined bractlets, 2-5 mm. long, entire or denticulate, shorter than the flowers; rays unequal to subequal, 1.5-6 cm. long; pedicels 3-10 mm. long; fruit oval to orbicular, 2-4 mm. long, 2-3 mm. broad, not constricted at the commissure, the ribs low and corky, about as broad as the usually reddish-brown intervals, the lateral ribs of the two carpels closely contiguous and forming a broad flat band and with much greater surface display than the dorsal ribs; oil tubes

moderately large; seed not very oily, not sulcate or only very shallowly so under the tubes, the face plane to concave. Along streams, in marshes and other wet places in e., cen. and n. Tex., May-Sept.; throughout e. U.S. and Can., s. to Ga. and La., w. to the Dakotas and Tex.

7. BERULA HOFFM. WATER-PARSNIP

A genus of two species, one circumboreal, the other African.

1. *Berula erecta* (Huds.) Cov. Plants slender, erect, stoloniferous, perennial from fascicled fibrous roots, 2-8 dm. high; leaves narrowly oblong, to 3 dm. long and 1 dm. wide, pinnate; leaflets oblong, distinct, subentire to serrate or lobed, those of the submerged leaves decomposed; cauline leaves reduced, the leaflets often linear; inflorescence of compound umbels; peduncles terminal and axillary, 2-8 cm. long; involucre of 6 to 8 linear to lanceolate unequal foliaceous scarious-margined entire to incisely toothed bracts, 5-15 mm. long; involucl of 4 to 8 linear to lanceolate acute entire bractlets, 1-5 mm. long; rays 6 to 15, subequal, spreading-ascending, 1-2 cm. long; pedicels 2-5 mm. long; flowers white, the minute calyx teeth subulate, the stylopodium conic; carpophore divided to the base, the halves wholly adnate to the mericarps; fruit oval to orbicular, 1.5-2 mm. long, compressed laterally, the filiform ribs obscure in the thick corky pericarp; oil tubes numerous about the seed, the seed face plane; strengthening cells lacking. *B. pusilla* (Nutt.) Fern. In wet places in the Blackland Prairies, Plains Country and Trans-Pecos, May-Nov.; throughout the U.S. and adj. Can., s. to Guat.; also Eur. and the Medit. region.

8. BIFORA HOFFM.

A genus of 4 species, three in the Mediterranean region and the Caucasus, the other American.

1. *Bifora americana* (DC.) Benth. & Hook. Plant slender, branching, annual with a slender taproot, 25-75 cm. high, glabrous or somewhat scaberulous; leaves ovate-oblong, to 5 cm. long and 3 cm. wide, ternate-pinnately decomposed, the ultimate divisions filiform, distinct, obtuse, glabrous; inflorescence of compound umbels; peduncles slightly scaberulous at the summit, terminal and axillary; involucre of a few small entire to pinnatifid linear bracts; involucl of bractlets like the bracts, shorter than or equaling the flowers; rays 4 to 14, spreading-ascending, 15-35 mm. long; pedicels about 2 mm. long; flowers white, the outer petals frequently radiant, the calyx teeth evident to obsolete, the stylopodium low-conic; carpophore divided to the base; fruit subglobose and didymous, 2-3 mm. long, 4-5 mm. broad, compressed laterally and constricted at the commissure, glabrous, the ribs filiform, the pericarp very thin and hard; oil tubes lacking, the seed face deeply and broadly concave. Weedy in prairies, fields and on rocky hills, mostly in n. and cen. Tex., Apr.-June; in Tex. and adj. Okla. and Ark.

9. CORIANDRUM L. CORIANDER

A genus of three species of the Mediterranean region.

1. *Coriandrum sativum* L. Plant slender, erect, caulescent, herbaceous, annual, from slender taproots, 2-7 dm. high; basal leaves ovate, to 15 cm. long and 10 cm. wide, simple and ternately or pinnately lobed or pinnate; leaflets flabelliform, cuneate at the base, variously toothed or incised; cauline leaves pinnately dissected, the ultimate divisions of some of the upper leaves linear to filiform, obtuse, entire; inflorescence of compound umbels; peduncles terminal and lateral, 3-10 cm. long, occasionally abortive; involucre lacking or of a single bract; involucl dimidiate, of a few linear bractlets 2-4 mm. long; rays 2 to 8, 1-2.5 cm. long; pedicels 2-5 mm. long; petals white or rose, the outer ones radiant; calyx teeth ovate-lanceolate, unequal, the outer ones to 1 mm. long, the stylopodium conic; carpophore divided to the base; fruit orbicular, terete, 1.5-5 mm. in diameter, with a hard pericarp, glabrous, the mericarps boat-shaped, not separating

readily at maturity, the primary ribs filiform, the secondary filiform or obscure; oil tubes lacking, the seed face concave. Sporadically escaped from cult. at various places in s. and cen. Tex., Apr.-July; nat. of the Old World, widely introd. in W. Hemis.

10. DAUCOSMA ENGELM. & GRAY

A monotypic genus, apparently related to *Ptilimnium*.

1. *Daucosma laciniatum* Gray. Plant slender, erect, caulescent, branching, herbaceous, annual, 9-12 dm. high, from slender taproots; leaves triangular-ovate, ternate-pinnately dissected, to 10 cm. long and 11 cm. wide, the ultimate divisions lanceolate, laciniate; inflorescence of compound umbels; peduncles terminal and axillary, 1.5-10 cm. long, callous-roughened above, exceeding the leaves; involucre of conspicuously pinnately parted bracts equaling or longer than the rays; involucre of bractlets like the bracts, equaling or longer than the pedicels; rays 14 to 17, 2-5 cm. long, spreading-ascending; pedicels about 20, spreading, 3-9 mm. long; flowers white, the conspicuous calyx teeth subulate, the stylopodium conic; carpophore divided to the base; fruit ovoid-oblong, 3-4 mm. long, about 2 mm. broad, compressed laterally, glabrous, the dorsal ribs broad and low, the lateral prominent, forming an acute ridge around the fruit; oil tubes solitary in the intervals and 2 on the commissure, the seed face plane. *Ptilimnium laciniatum* (Engelm. & Gray) O. Ktze. Moist places in s. Blackland Prairies and on the Edwards Plateau, May-Aug.; endemic.

11. PTILIMNIUM RAF. MOCK BISHOP'S-WEED

Plants slender, erect, caulescent, branching, herbaceous, annual, from a fascicle of fibrous roots; leaves pinnately decompose with filiform ultimate divisions or the leaves reduced to fistulose sheathing petioles; inflorescence of compound umbels, the peduncles terminal and axillary; involucre of entire or pinnatifid bracts; involucre of entire bractlets; rays few to numerous, spreading-ascending to spreading, the pedicels spreading; flowers white, rarely pink, the calyx teeth small to prominent, the stylopodium conic; carpophore bifid at the apex or cleft to the middle; fruit ovoid to suborbicular, compressed laterally, the dorsal ribs filiform, rounded or acute, the lateral ribs small to corky-winged, forming a band around the fruit; oil tubes solitary in the intervals and 2 on the commissure, the seed face plane.

A genus of five species of southeastern and south-central United States.

- 1. Leaf segments crowded, appearing verticillate; styles 1.5-3 mm. long; plant robust, 8-15 dm. high 2. *P. costatum*.
- 1. Leaf segments not crowded; styles 0.2-1.5 mm. long; plants 2-8 dm. high (2)
- 2(1). Leaf segments usually 3 at a node on the rachis; bracts usually 3-cleft; styles 0.2-0.5 mm. long, not strongly recurved 1. *P. capillaceum*.
- 2. Leaf segments usually 2 at a node on the rachis; bracts usually entire; styles 0.5-1.5 mm. long, strongly recurved 3. *P. Nuttallii*.

1. *Ptilimnium capillaceum* (Michx.) Raf. Plant 1-8.5 dm. high; leaves verticillate at the nodes, polymorphic in submerged forms, broadly oblong, to 13 cm. long and 4 cm. wide, pinnately decompose, the segments usually filiform, 3 at a node on the rachis; peduncles 2.5-10.5 cm. long, exceeding the leaves; involucre of several pinnately cleft or rarely entire bracts about one half as long as the rays; involucre of filiform bractlets shorter than the pedicels; rays 4 to 20, spreading, subequal, 1-3.5 cm. long; pedicels 5 to 20, 3-12 (usually 4-6) mm. long; calyx teeth small, persistent; styles 0.2-0.5 mm. long, not strongly recurved; fruit broadly ovoid, 1.5-3 mm. long, 1.5-2 mm. broad, the lateral ribs conspicuous. In wet places in the e. half of Tex., May-Aug.; from Mass., s. to Fla., w. to Mo., Kan. and Tex.

2. *Ptilimnium costatum* (Ell.) Raf. Plant 8-15 dm. high; leaves oblong, to 14 cm. long and 7 cm. wide, pinnately decompose, the ultimate divisions filiform, crowded, appearing verticillate; peduncles 7-14 cm. long, exceeding the leaves; involucre of very short usually entire bracts; involucre of usually entire bractlets shorter than the pedicels;

rays about 20, spreading, subequal, 1.5-4 cm. long; pedicels 15 to 20, spreading, 4-5 mm. long; calyx teeth conspicuous, deltoid, acute to subacuminate, persistent; styles 1.5-3 mm. long; fruit ovoid, 2-4 mm. long, 2-3 mm. broad. In swamps and other wet places in the e. half of Tex., June-Oct.; from N.C. to Ga., w. to Mo. and Tex.

3. *Ptilimnium Nuttallii* (DC.) Britt. Plant 3-6 dm. high; leaves oblong, to 9 cm. long and 4 cm. wide, pinnately decomposed, the ultimate divisions filiform, usually 2 at a node on the rachis; peduncles 4-12 cm. long; involucre of filiform mostly entire bracts much shorter than the rays; involucre of filiform entire bractlets shorter than the pedicels; rays 25 to 30, spreading, subequal, 15-35 mm. long; pedicels 25 to 30, spreading, 3-8 mm. long; calyx teeth conspicuous, linear-lanceolate, persistent; styles 0.5-1.5 mm. long, strongly recurved; fruit ovoid, 1-1.5 mm. long, 1 mm. broad, the lateral ribs inconspicuous, only slightly corky-thickened. In moist sandy soil, in prairies and other moist places in the e. half of Tex., Apr.-July; from Ill., s. to La. and w. to Kan. and Tex.

Plants described as *P. texense* Coult. & Rose, formerly referred to *P. costatum* by Mathias and Constance, are considered by Easterly (Brittonia 9: 144. 1957) to be of possible hybrid origin, combining the fruit characteristics of *P. Nuttallii* with the vegetative characteristics of *P. capillaceum*. The center of distribution apparently is in Robertson County and the taxon is found through a large area of eastern Texas in acid bogs and marsh land, flowering July to August.

12. CYNOSCIADIUM DC.

A monotypic genus.

1. *Cynosciadium digitatum* DC. Plant slender, erect, caulescent, herbaceous, annual, 15 cm. high, dichotomously branching in the inflorescence, from a fascicle of fibrous roots; basal leaves linear-lanceolate, tapering at base, acute at apex, entire and septate, to 12 cm. long and 5 mm. wide; cauline leaves 3 to 5, palmately parted with narrow elongate divisions; inflorescence of compound umbels, the peduncles (1.5-8 cm. long) axillary and terminal; involucre and involucre usually lacking or the latter of a few linear bractlets shorter than the pedicels; rays 2 to 10, unequal, slender, spreading-ascending, 1-4 cm. long or some umbellets frequently sessile or proliferating; pedicels 2 to 11, 5-20 mm. long, spreading-ascending; flowers white, the prominent calyx teeth ovate, the stylopodium conic; carpophore bifid at the apex; fruit ovoid, 2-3 mm. long, 1.5-2.5 mm. broad, glabrous, prominently beaked at the apex, rounded at the base, slightly compressed laterally or nearly terete, the narrow dorsal ribs prominent, the lateral ribs broadly corky-winged; oil tubes solitary in the intervals and 2 on the commissure, the seed face plane. In wet places in the Coastal and Blackland prairies of Tex., May-July; from Tex. n. to s. Mo. and e. to La.

13. LIMNOSCIADIUM MATH. & CONST.

Plants low and diffuse to erect, slender, caulescent, branching, herbaceous, annual, from a fascicle of fibrous roots; leaves entire and septate or pinnate with narrow elongate divisions; inflorescence dichotomously branching, of compound umbels, the peduncles axillary and terminal or some umbels sessile; involucre lacking or of a few narrow entire bracts; involucre of several narrow entire bractlets shorter than the pedicels; rays few, unequal, spreading-ascending; flowers white, the prominent calyx teeth ovate-lanceolate, the stylopodium conic; carpophore shortly bifid at the apex; fruit oblong-oval to orbicular, rounded at apex and base, slightly compressed dorsally, glabrous, the dorsal ribs filiform, the lateral broadly corky-winged; oil tubes solitary in the intervals and 2 on the commissure, the seed face plane.

A genus of 2 species, inhabiting wet places in the south-central United States.

1. Plant erect or assurgent; calyx teeth 0.5 mm. or less long, attached well below and shorter than the stylopodium; fruit oblong-oval, 2-4 mm. long, 1-2 mm. broad . . .
 1. *L. pinnatum*.

1. Plant low and diffuse; calyx teeth to 1.5 mm. long, attached shortly below and equaling the stylopodium; fruit oval to orbicular, 2-3 mm. long, 2 mm. broad 2. *L. pumilum*.

1. *Limnoscium pinnatum* (DC.) Math. & Const. Plant erect or assurgent, 1-8 dm. high; basal leaves linear-lanceolate, acute at the apex, tapering at the base, to 20 cm. long and 25 mm. wide, entire and septate or pinnate, the terminal division elongate; cauline leaves pinnate or the lowest and uppermost entire, with 2 to 9 linear to linear-lanceolate divisions, acute at both ends; peduncles 1-8 cm. long or some umbels sessile; involucre of several linear or linear-lanceolate reflexed bracts 2-6 mm. long; involucre of several linear bractlets 1-5 mm. long; rays 3 to 12, slender, 5-35 mm. long; pedicels 4 to 20, 2-8 mm. long; calyx teeth 0.5 mm. long or less, attached well below and shorter than the stylopodium; fruit oblong-oval, 2-4 mm. long, 1-2 mm. broad, the dorsal ribs low, the lateral corky wings slightly broader. *Cynosciadium pinnatum* DC. In wet places in the e. half of Tex., s. to the Rio Grande Plains, May-June; from Tex. and La., n. to Ill. and Kan.

2. *Limnoscium pumilum* (Engelm. & Gray) Math. & Const. Plant low and diffuse, 5-40 cm. high or long; basal leaves lanceolate to linear-lanceolate, acute at the apex, tapering at the base, to 8 cm. long and 8 mm. wide, entire and septate or pinnate, the terminal division elongate; cauline leaves pinnate or entire, with 3 to 7 filiform to lanceolate divisions, acute at the apex, tapering at the base; peduncles 5-75 mm. long or frequently some umbels sessile; involucre lacking or of a few minute bracts; involucre of several linear to linear-lanceolate bractlets 2-4 mm. long; rays 3 to 8, slender, 1-5 cm. long; pedicels several, 2-4 mm. long; calyx teeth to 1.5 mm. long, attached shortly below and about equaling the stylopodium; fruit oval to orbicular, 2-3 mm. long, 2 mm. broad, the dorsal ribs filiform, the lateral wings broad and corky. *Cynosciadium pumilum* (Engelm. & Gray) Coult. & Rose. In wet places in cen. and s. Tex., Mar.-June; endemic.

14. BUPLEURUM L. THOROUGHWAX

Plants low or slender, erect or spreading, herbaceous or woody at base, caulescent or rarely acaulescent, alternately or dichotomously branching, glabrous and often glaucous, annuals or perennials, rarely biennials, from woody or fibrous taproots; basal leaves entire with usually parallel venation; cauline leaves usually sessile and clasping, auriculate or perfoliate, the petioles sheathing; inflorescence of compound umbels, the peduncles terminal and lateral; involucre of conspicuous foliaceous bracts or lacking; involucre of broad foliaceous often connate and rarely colored bractlets that sometimes exceed the flowers and fruit; rays few, spreading-ascending to divaricate, the pedicels spreading; flowers yellow, sometimes greenish or purplish-tinged, the calyx teeth obsolete, the stylopodium depressed-conic; carpophore divided to the base; fruit oblong to orbicular or ellipsoid, slightly compressed laterally and constricted at the commissure, glabrous or roughened or tuberculate, the ribs filiform; oil tubes numerous and continuous about the seed or several in the intervals and on the commissure, sometimes obscure or lacking, the seed face plane.

A chiefly circumboreal genus, with the bulk of its approximately 100 species in Eurasia.

1. Rays 4 to 10; fruit oblong-oval, smooth 1. *B. rotundifolium*.
1. Rays 2 to 5; fruit ovoid-globose, tuberculate or rugose . . 2. *B. lancifolium*.

1. *Bupleurum rotundifolium* L. Plant annual, 2-6 dm. high; basal and lower cauline leaves oblong- to obovate-lanceolate, to 8 cm. long and 5 cm. wide, rounded at the apex, subpetiolate or perfoliate at the base; upper cauline leaves numerous, ovate, perfoliate; peduncles 2-7 cm. long; involucre lacking; involucre of 5 or 6 broadly ovate to obovate acuminate bractlets; bractlets 8-12 mm. long, 6-10 mm. wide, united at the base, two to three times as long as the flowers and fruit; rays 4 to 10, spreading-ascending, 5-15 mm. long; pedicels 10 to 12, equaling or shorter than the fruit; flowers yellow; fruit oblong-oval, 2.5-3 mm. long, 1.5-2 mm. broad, dark-purplish-brown, smooth, the ribs filiform; seed face slightly concave. Sporadically introd. in the Blackland Prairies, Apr.-June; a Medit. species introd. in cen. and e. U.S.

2. *Bupleurum lancifolium* Hornem. Plant annual, about 5 dm. high; basal leaves linear to oblong-lanceolate, subpetiolate; cauline leaves numerous, broadly ovate, acute to acuminate, perfoliate; peduncles 1-8 cm. long; involucre lacking; involucre of 5 or 6 suborbicular to obovate-rotund short-acuminate bractlets; bractlets 8-15 mm. long, united at the base or rarely to the middle, twice as long as the flowers and fruit; rays 2 to 5, divaricate, 5-25 mm. long; pedicels 10 to 20, slender, about as long as the fruit; flowers yellow; fruit ovoid-globose, 3-5 mm. long, about 3.5 mm. broad, black, tuberculate or rugose, the ribs prominent; seed face plane. *Bupleurum subovatum* Link. Sporadically introd. in the Coastal Prairies and s. Rio Grande Plains, Apr.-July; a Medit. species introd. in various parts of the U.S. probably in bird-seed.

15. AMMI L. BISHOP'S-WEED

Plants slender, erect, caulescent, branching, herbaceous, annuals, biennials or perennials from slender taproots; leaves ternate-pinnate or pinnately dissected, the ultimate divisions filiform to lanceolate; inflorescence of compound umbels, the peduncles terminal and axillary; involucre of numerous entire or divided bracts, the involucre of numerous entire bractlets; rays numerous, spreading-ascending, the pedicels spreading; flowers white, the calyx teeth minute, the stylopodium depressed-conic; carpophore entire or divided to the base; fruit oblong to ovoid, compressed laterally, glabrous, the ribs acute; oil tubes solitary in the intervals and 2 on the commissure, the seed face plane.

An Old World genus of 6 species, chiefly of the Mediterranean region.

1. Inflorescence borne on a discoid receptacle; umbels compact in fruit; carpophore entire 1. *A. Visnaga*.
1. Inflorescence not borne on a discoid-receptacle; umbels spreading in fruit; carpophore divided to the base 2. *A. majus*.

1. *Ammi Visnaga* (L.) Lam. **BISNAGA**. Plant erect, branching, biennial (?), 2-8 dm. high, glabrous; leaves ovate-triangular, to 20 cm. long, pinnately decompose; ultimate divisions of leaf linear to filiform, setaceous to cuspidate-acute, divaricate, entire; cauline leaves ternately or pinnately dissected; peduncles 8-14 cm. long; involucre of numerous setiform-acute bractlets, ascending at maturity and equaling or exceeding the pedicels; rays 60 to 100, subfiliform, unequal, 2-5 cm. long, spreading in flower but rigidly contracted in fruit, borne on a discoid receptacle; pedicels numerous, filiform, unequal, to 13 mm. long, spreading in flower but rigidly contracted in fruit, borne on a discoid receptacle; pedicels numerous, filiform, unequal, to 13 mm. long, spreading in flower but rigidly contracted in fruit, borne on a small discoid receptacle; carpophore entire; fruit oblong-ovoid to ovoid, 2-2.5 mm. long, 1.5-1.7 mm. broad. Sporadically introd. in waste places, thus far known only in the Trans-Pecos, Apr.-June; a Euras. species that is widely introd. in the W. Hemis.

2. *Ammi majus* L. Plant erect, branching, annual, 2-8 dm. high, the inflorescence scabrous; leaves oblong, to 2 dm. long and 14 cm. wide, ternate or pinnate; leaflets lanceolate, obtuse to acute at the apex, cuneate at the base and somewhat recurved on the rachis, setulose-serrate with minute subequal teeth; cauline leaves bipinnate with linear divisions, the uppermost greatly reduced; peduncles 8-14 cm. long; involucre of numerous linear-acuminate scarious-margined bractlets, spreading to reflexed at maturity and slightly shorter than the pedicels; rays 50 to 60, subfiliform, 2-7 cm. long, spreading to ascending in flower but spreading in fruit, scabrous; pedicels numerous, filiform, unequal, to 1 cm. long, spreading to ascending; carpophore divided to the base; fruit oblong, 1.5-2 mm. long, 1 mm. or less broad. Sporadically introd. in e. and s. Tex., Mar.-June; a Euras. species that is widely introd. in the W. Hemis.

16. CONIUM L.

A genus of 2 species, one circumboreal in damp places, the other African.

1. *Conium maculatum* L. **POISON HEMLOCK**. Plant slender, erect, glabrous, 5-30 dm. high, biennial from stout taproots, the branching stems usually spotted; leaves broadly ovate, 1.5-3 dm. long, 5-30 cm. broad, pinnately decompose, the ultimate divisions

pinnately incised; inflorescence a compound dichasium of compound umbels, the peduncles terminal and axillary; involucre of short ovate-acuminate bracts; involucre of numerous bractlets like the bracts, with a conspicuous midrib, shorter than the pedicels; rays numerous, subequal, 15-25 mm. long, spreading-ascending; pedicels spreading, 4-6 mm. long; flowers white, the calyx teeth obsolete, the stylopodium depressed-conic; carpophore entire; fruit broadly ovoid, 2-2.5 mm. long, about 2 mm. broad, compressed laterally, glabrous, the prominent obtuse ribs undulate and crenate; oil tubes very small and numerous, irregular, the seed face deeply and narrowly sulcate. Sporadically introd. in wet places in the s. half of Tex., May-Aug.; a Euras. species widely introd. throughout temp. regions in the World.

Fatally poisonous if eaten.

17. FOENICULUM ADANS. FENNEL

A genus of about 5 species, chiefly of the Mediterranean region.

1. *Foeniculum vulgare* Mill. COMMON FENNEL. Plant rather stout, erect, branching, glabrous and glaucous, with a strong anise odor, perennial or biennial from taproots, 9-21 dm. high; leaves ovate to ovate-triangular, 3 dm. long, 4 dm. wide, pinnately decomposed, dark-green, the ultimate divisions filiform; inflorescence of compound umbels; peduncles terminal and axillary, 15-65 mm. long; involucre and involucre lacking; rays 15 to 40, spreading-ascending in flower, ascending to suberect in fruit, somewhat unequal, 1-6.5 cm. long; pedicels several, spreading, 2-10 mm. long, subequal; flowers yellow, the calyx teeth obsolete, the stylopodium conic; carpophore divided to the base; fruit 3.5-4 mm. long, 1.5-2 mm. broad, oblong, slightly compressed laterally, glabrous, the prominent ribs acute or obtuse; oil tubes solitary in the intervals and 2 on the commissure, the seed face plane or slightly concave. Introd. in marshes and low areas in coastal and s. Tex., Mar.-May; a Medit. species that is adv. throughout the W. Hemis.

18. APIUM L. CELERY

Plants slender or stout, erect, ascending or prostrate, caulescent (usually), branching, herbaceous, glabrous, annual, biennial or a somewhat woody-based perennial from taproots or creeping rootstocks rooting at the nodes; leaves simply pinnate to ternate-pinnately decomposed; inflorescence of compound (rarely simple) umbels, the peduncles lateral and terminal or some umbels sessile; involucre and involucre lacking to conspicuous; rays usually few, spreading-ascending, the pedicels spreading to ascending; flowers white or greenish, the calyx teeth minute or obsolete, the stylopodium short-conic to depressed; carpophore entire, shortly bifid or more or less deeply 2-cleft; fruit oblong-oval to orbicular or ellipsoid, compressed laterally and somewhat constricted at the commissure, glabrous or rarely somewhat setulose, the prominent filiform ribs subequal and obtuse; oil tubes solitary in the intervals and 2 on the commissure, the seed face plane.

A cosmopolitan genus of about 30 species.

1. Plant annual; leaves pinnately or ternate-pinnately decomposed, the leaflets filiform to linear 1. *A. leptophyllum*.

1. Plant perennial or biennial; leaves pinnate, the leaflets orbicular to ovate 2. *A. graveolens*.

1. *Apium leptophyllum* (Pers.) F. v. Muell. Plant annual, alternately branched above, 5-60 cm. high; leaves oblong-ovate, to 10 cm. long and 8 cm. wide, 3- or 4-pinnately decomposed, the leaflets linear to filiform; umbels simple or compound, sessile or pedunculate, the peduncles to 2 cm. long; involucre and involucre lacking; rays 3 to 5, 1-2.2 cm. long; pedicels 2-8 mm. long; calyx teeth inconspicuous; carpophore shortly 2-cleft; fruit ovoid, 1.2-3 mm. long, 1.5-2 mm. broad, glabrous. *Apium ammi* (Jacq.) Urban. Widely distributed in moist or wet soil in the Coastal and Blackland prairies and the Rio Grande Plains, Mar.-June; from s. U.S. and W.I., s. to S.A.; a pan-trop. weed.

2. *Apium graveolens* L. WILD CELERY. Plant perennial, erect or ascending from a taproot, not rooting at the nodes, 5-15 dm. high; leaves oblong to obovate, to 18 cm.

long and 8 cm. wide, pinnate with few pairs of ovate to suborbicular leaflets that are usually 3-lobed to near the middle; cauline leaves frequently cuneate, sometimes lacinate; umbels sessile or short-pedunculate, the peduncles to 12 mm. long; involucre and involucrel lacking; rays 7 to 16, to 25 mm. long; pedicels 1-6 mm. long; calyx teeth minute but evident; carpophore shortly bifid; fruit suborbicular to ellipsoid, about 1.5 mm. long, 1.5-2 mm. broad. *Celeri graveolens* (L.) Britt. Occasionally in wet places in the Trans-Pecos, June-July; a Euras. species widely adv. in the W. Hemis.

19. PETROSELINUM HOFFM.

A European genus of 3 species, very closely related to *Apium*.

1. *Petroselinum crispum* (Mill.) Mansf. PARSLEY. Plant slender, erect, caulescent, branching, glabrous, herbaceous, biennial from taproots, 3-13 dm. high; leaves ternate-pinnately or pinnately decomposed, ovate-triangular, the ultimate divisions ovate-lanceolate to linear, distinct, toothed or lobed; inflorescence of compound umbels; peduncles terminal and axillary, 3-8 cm. long; involucre of a few inconspicuous entire bracts or wanting; involucrel of 5 to 6 linear acute entire bractlets shorter than the yellow or greenish-yellow flowers; rays 10 to 20, subequal to unequal, spreading-ascending, 1-5 cm. long; pedicels spreading, 2-5 mm. long; calyx teeth obsolete, the stylopodium low-conic; carpophore divided to the base or 2-cleft to the middle; fruit ovoid-oblong, 2-4 mm. long, 1.5-3 mm. broad, compressed laterally, glabrous, the prominent ribs filiform; oil tubes solitary in the intervals and 2 on the commissure, the seed face plane. Sporadically escaped from cult. in the s. Blackland Prairies; a Eur. species adv. throughout the W. Hemis.

20. CHAEROPHYLLUM L. CHERVIL

Plants erect or spreading, caulescent, branching, glabrous or pubescent, herbaceous, annual or biennial from taproots or tubers; leaves ternate-pinnately decomposed, the ultimate divisions or lobes small; inflorescence of compound umbels, the peduncles terminal and axillary or frequently obsolete; involucre usually lacking; involucrel of numerous conspicuous bractlets that are longer or shorter than the pedicels and reflexed or spreading in fruit; rays few, spreading-ascending, the pedicels spreading; flowers white (rarely red or yellow), the calyx teeth obsolete, the stylopodium conic; carpophore 2-cleft part-way to the base; fruit linear to narrowly oblong, beaked or beakless, often narrowed toward the apex, rounded or narrowed toward the base, compressed laterally, the prominent ribs unwinged and narrower or broader than the intervals; oil tubes small, usually solitary in the intervals and 2 on the commissure, the seed face sulcate; each rib with a large group of strengthening cells.

A circumboreal genus of about 40 species, chiefly Eurasian.

1. Ovaries and fruits glabrous 1. *C. Tainturieri* var. *Tainturieri*.
 1. Ovaries and fruits conspicuously pubescent 1. *C. Tainturieri* var. *dasycarpum*.

1. *Chaerophyllum Tainturieri* Hook. var. *Tainturieri*. Plant erect, 1.5-9 dm. high, annual, the stems solitary and usually branching near the base, sparsely hispid or hispidulous above and densely retrorsely hispid beneath to glabrate; leaves oblong to ovate-oblong, to 12 cm. long and 10 cm. wide, ternate-pinnately dissected, the ultimate divisions distinct or more or less confluent, linear to ovate, obtuse to acute, glabrous to more or less hispid; peduncles usually obsolete; involucre of several conspicuous ovate rounded to acute ciliate-margined bractlets usually longer than the pedicels and spreading or reflexed in fruit; rays 1 to 5 (usually about 3), to 75 mm. long; pedicels 3 to 20, to 1 cm. long; fruit narrowly oblong, beaked or narrowed toward the apex, rounded to narrowed toward the base, 4-8 mm. long, 1.5-2 mm. broad, the ribs narrower to much broader than the intervals. *C. texanum* Coult. & Rose. In prairies, woodlands and alluvial thickets, widespread but chiefly in the e. half of Tex., Mar.-May; from Va., s. to Fla., w. to Kan., Mo., Tex. and Ariz.

Var. *dasycarpum* Wats. Similar to var. *Tainturieri* in vegetative characters but the ovaries and fruits are conspicuously pubescent. With the typical phase chiefly in the e. half of Tex., Mar.-May; from Tex. e. to Ala. and n. to Mo.

21. CRYPTOTAENIA DC. HONEWORT. WILD CHERVIL

A chiefly circumboreal genus of about 6 species.

1. *Cryptotaenia canadensis* (L.) DC. Plant slender, erect, caulescent, branching, glabrous, herbaceous, perennial from slender fascicled roots, 3-9 dm. high; leaves ternate, oblong-ovate, to 13 cm. long and 15 cm. wide; leaflets oblong-lanceolate to obovate, to 13 cm. long and 8 cm. wide, short-acuminate at the apex, cuneate at the base, closely and doubly serrate or occasionally deeply 2- or 3-lobed; upper cauline leaves reduced to lanceolate dentate bracts; inflorescence of compound umbels, the peduncles terminal and lateral, usually paniculate; involucre and involucl lacking or of few inconspicuous bracts or bractlets; rays 2 to 7, unequal, ascending, 1-6 cm. long, the 2 to 10 unequal pedicels ascending and to 35 mm. long; flowers white, the calyx teeth obsolete or minute, the styles erect or reflexed, the stylopodium slender-conic; carpophore divided to the base; fruit linear-oblong, compressed laterally, 3.5-8 mm. long, 1.5-3 mm. broad, glabrous, the filiform obtuse ribs subequal and conspicuous; oil tubes 1 to 4 in the intervals and 2 on the commissure, the seed face plane. *Deringia canadensis* (L.) O. Ktze. Moist woodlands in the Timber Belt, May; from e. Can., s. to Ga., w. to Man., Neb. and Tex.; also Japan and s. China.

22. OSMORHIZA RAF. SWEET CICELY

Plants slender to rather stout, erect or decumbent at the base, caulescent, branching, herbaceous, perennial from thick fascicled roots; leaves ternate or ternate-pinnate, the lanceolate to orbicular leaflets serrate to pinnatifid and with mucronate teeth or lobes; inflorescence of compound umbels, the peduncles terminal and lateral and usually exceeding the leaves; involucre usually lacking; involucl of several narrow foliaceous reflexed bractlets or lacking; rays few, slender, ascending to divaricate and reflexed, unequal, the pedicels spreading to divaricate; flowers white, purple, or greenish-yellow, the calyx teeth obsolete, the stylopodium conic; carpophore 2-cleft less than one half its length; fruit linear to oblong, cylindrical to clavate, obtuse, tapering, beaked or constricted at the apex, rounded or caudate at the base, compressed laterally, the filiform ribs acute; oil tubes obscure or lacking, the seed face concave or sulcate.

A genus of 11 species of East Asia and eastern North America, and of western North America to South America.

- 1. Fruit base obtuse and without appendages (or these rudimentary), glabrous; fruit 10-12 mm. long; style and stylopodium less than 0.5 mm. long 1. *O. bipatriata*.
- 1. Fruit base attenuate into prominent appendages; fruit conspicuously bristly at least at the base, 15-20 mm. long; style and stylopodium 2-4 mm. long 2. *O. longistylis*.

1. *Osmorhiza bipatriata* Const. & Shan. Plant slender, 2-6 dm. high, sparsely hirsutulous; leaves ovate, 4-12 cm. long and broad, ternate-pinnate; leaflets ovate to ovate-oblong, laciniately lobed to pinnatifid; peduncles 3-18 cm. long; involucre lacking; involucl of several linear ciliate bractlets 1-3 mm. long; rays 2 to 5, spreading-ascending, to 35 mm. long; pedicels spreading, 3-6 mm. long; flowers white, tinged with green or rose; stylopodium low-conic; carpophore cleft about one fourth of its length; fruit linear-fusiform, 10-12 mm. long, tapering into a short beak at the apex, acute or with rudimentary appendages at the base, glabrous (or with a few bristles at the very base). Known in Tex. only from Mt. Livermore, Davis Mts., in the Trans-Pecos, June-July; also N.L.

2. *Osmorhiza longistylis* (Torr.) DC. ANISE-ROOT. Plant rather stout, 6-10 dm. high, villous or hirsutulous; leaves orbicular, 8-25 cm. long, biternate or ternate-pinnate; leaflets ovate to oblong-lanceolate, acute, coarsely serrate, incised or pinnately lobed toward the

base, hirsutulous especially on the veins and margins; peduncles 5-13 cm. long; involucre of 1 to several linear or lanceolate foliaceous, ciliate, sharply reflexed bracts to 15 mm. long; rays 3 to 6, spreading-ascending, 1.5-5 cm. long; pedicels spreading-ascending, 5-8 mm. long; flowers white, the stylopodium high-conic; carpophore cleft about one third of its length; fruit oblong-fusiform, 15-20 mm. long, acute at the apex, caudate at the base, the appendages 4-6 mm. long, sparingly bristly on the ribs. Along streams in the Blackland Prairies and perhaps in the Timber Belt, rare; from e. Can., s. to Ala. and Tex., w. to Alta., Colo. and N.M.

23. SCANDIX L.

A genus of the Mediterranean region, comprising about a dozen species.

1. *Scandix Pecten-Veneris* L. VENUS'-COMB, CROW-NEEDLES. Plant 15-35 cm. high, hispid, annual from slender taproots, commonly branched from the base; leaves pinnately decomposed, oblong, to 14.5 cm. long and 7 cm. wide, the short linear ultimate divisions acute; peduncles terminal and lateral; involucre usually lacking; involucre of two bractlets connate at the base and lobed above, 4-15 mm. long, shorter than the flowers; rays 1 or 2, spreading-ascending, 1-3 cm. long; pedicels 8 mm. long to obsolete; flowers white, the outer petals radiant, the calyx teeth minute or obsolete, the stylopodium depressed; carpophore entire or bifid at the apex; fruit linear or narrowly oblong, 6-15 mm. long, 1-2 mm. broad, ciliate, terminating in an elongated linear beak 2-7 cm. long, compressed laterally, the beak hispid-ciliate on the margins, the filiform ribs obtuse and prominent; oil tubes very small, solitary in the intervals or obscure, the seed face sulcate. Adv. on the Coastal and Blackland prairies, Mar.-Apr.; a Euras. species that is adv. throughout the U.S. and in B.C.

24. TREPOCARPUS DC.

A monotypic genus of the southern United States.

1. *Trepocarpus Aethusae* Nutt. Plant slender, erect, 3-5.5 dm. high, caulescent, simple or branching, glabrous, herbaceous, annual from slender taproots; leaves pinnately decomposed, 8-10 cm. long, the short divisions linear and acute; cauline leaves little reduced upward; inflorescence of compound umbels; peduncles to 95 mm. long, lateral and opposite the leaves; involucre of 1 to several foliaceous entire or divided bracts to 15 mm. long; involucre of bractlets (3-8 mm. long) like the bracts; rays 2 to 4, spreading, to 15 mm. long, the 2 to 8 pedicels very short; flowers white, the calyx teeth linear and unequal, the stylopodium conic; carpophore divided to the base; fruit oblong-linear, 8-10 mm. long, slightly compressed laterally, glabrous, the primary ribs obsolete but 4 secondary ribs and the face of the commissure prominently corky; oil tubes small, solitary under the secondary ribs and 2 on the commissure, more or less imbedded in the seed and adhering to it, the seed face plane or slightly concave. Chiefly on river bottoms and terraces in the Timber Belt and Blackland and Coastal prairies, Apr.-June; from Tex., n. to Ark. and e. to S.C.

25. CUMINUM L.

A southern Mediterranean genus of 2 species.

1. *Cuminum Cyminum* L. CUMIN. Plants slender, glabrous, 2-3 dm. high, annual from slender taproots; basal leaves ovate, to 1 dm. long, ternately dissected, the entire ultimate divisions linear-filiform; peduncles terminal and lateral, to 1 dm. long; involucre of 5 to 7 linear and entire or ternately dissected bracts with unequal linear divisions to 5 cm. long and reflexed; involucre of bractlets like the bracts, to 1 cm. long; rays 2 to 6, spreading-ascending, to 25 mm. long, unequal; pedicels to 8 mm. long; flowers white or rose-color, the outer petals radiant, the subulate calyx teeth longer than the short styles, the conic stylopodium attenuate; carpophore divided to the base; fruit oblong, 6-7 mm. long, 2.5-3

mm. broad, slightly compressed laterally, attenuate at the apex and base, setulose and bristly, the filiform primary ribs minutely setulose, the bristly secondary ribs very prominent; oil tubes solitary in the intervals and 2 on the commissure, the seed face slightly concave. A Medit. plant escaped from cult. in vic. of El Paso.

26. AMMOSELINUM T. & G. SAND-PARSLEY

Plants low, slender, erect or diffuse, caulescent, branching, roughened, herbaceous, annual from slender taproots; leaves ternately or ternate-pinnately decomposed, the ultimate divisions linear to spatulate; inflorescence of compound umbels, the peduncles axillary and terminal or the umbels often sessile; involucre usually lacking; involucrel of several narrow entire or toothed bractlets; rays few, spreading-ascending or spreading, unequal, the few pedicels unequal and slender to obsolete; flowers white, the calyx teeth obsolete, the stylopodium low-conic; carpophore 2-cleft at the apex; fruit oblong-ovoid to ovoid, compressed laterally, the prominent ribs acute or rounded and coarsely scabrous to glabrous, the lateral ribs (with or without corky appendages or callous teeth) of the two mericarps closely contiguous and appearing to form a single broad rib and often covering the commissure with corky tissue; oil tubes 1 to 3 in the intervals and 2 to 4 on the commissure, the seed face plane to concave; pericarp composed almost exclusively of strengthening cells.

A genus of 4 species of the south-central and southwestern United States and adjacent Mexico; one species in southern South America.

- 1. Umbels sessile; fruit glabrous to sparsely roughened; ribs acute, the lateral without corky appendages 1. *A. Butleri*.
- 1. Umbels pedunculate; fruit roughened with callous teeth; ribs rounded, the lateral with corky appendages 2. *A. Popei*.

1. *Ammoselinum Butleri* (Wats.) Coult. & Rose. Plant branching from the base, 4-5 cm. high; leaves oblong, to 25 mm. long and 15 mm. wide, biternate or ternate-pinnate; ultimate divisions of leaves linear, obtuse, mucronulate, glabrous; umbels sessile in the axils; involucre lacking; involucrel of a few foliaceous bractlets, shorter than the pedicels; rays 2 to 6, unequal, to 2 cm. long to obsolete; pedicels 1 to 10, unequal, 1-6 mm. long; fruit ovoid, 2.5-3 mm. long, 1-1.5 mm. broad, glabrous to sparsely roughened with callous teeth, the subacute ribs prominent; oil tubes solitary in the intervals and 2 on the commissure, the seed face plane or nearly so. Principally in bottomlands and moist woodlands in the Timber Belt and the Blackland and Coastal prairies, Mar.-Apr.; also Okla. and Ark.

2. *Ammoselinum Popei* T.&G. Plant branching from the base, 1-3.5 dm. high; leaves oblong-ovate, to 4 cm. long and wide, ternate-pinnately dissected; ultimate divisions of leaves linear, obtuse, mucronulate, glabrous or roughened with callous teeth; peduncles axillary and terminal, 1.5-4 cm. long; involucre lacking or of a solitary foliaceous bract; involucrel of several linear bractlets, longer than the pedicels; rays 3 to 10, unequal, to 2.5 mm. long; pedicels 3 to 12, to 11 mm. long; fruit oblong-ovoid, 3-5 mm. long, about 3 mm. broad, more or less roughened with callous teeth, the ribs rounded, the lateral ribs with corky appendages; oil tubes solitary in the intervals and 2 on the commissure; seed face slightly concave. In sandy soil throughout w. and s. Tex., Feb.-June; from Okla., s. to N.L. and w. to N.M.

27. SPERMOLEPIS RAF. SCALE-SEED

Plants slender, erect or spreading, caulescent, branching, glabrous, herbaceous, annual from slender taproots; leaves ternately or ternate-pinnately decomposed, the ultimate divisions linear to filiform; inflorescence of compound umbels, the terminal and axillary peduncles exceeding the leaves; involucre lacking; involucrel of a few linear bractlets usually shorter than the pedicels; rays few, erect to divaricate, the few pedicels spreading or some of the flowers sessile; flowers white, the calyx teeth obsolete, the stylopodium low-conic; carpophore 2-cleft at the apex; fruit ovoid, compressed laterally and slightly constricted at the commissure, smooth, tuberculate or echinate, the filiform ribs rounded; oil tubes 1 to 3 in the intervals and 2 on the commissure, the seed face sulcate.

A genus of 5 species, three in the southeastern and central United States and adjacent Mexico, one in southern South America, and the fifth in the Hawaiian Islands.

- 1. Fruit covered with short echinate bristles; plants usually low and somewhat spreading; leaves ovate3. *S. echinata*.
- 1. Fruit smooth or tuberculate; plants slender, erect; leaves oblong to oblong-ovate (2)
- 2(1). Rays divaricate, subequal; ultimate leaf divisions linear1. *S. divaricata*.
- 2. Rays erect, unequal; ultimate leaf divisions filiform ...2. *S. inermis*.

1. *Spermolepis divaricata* (Walt.) Raf. Plant slender, erect, 1-7 dm. high; leaves oblong to oblong-ovate, to 5 cm. long and 35 mm. wide, ternately or ternate-pinnately decomposed; ultimate divisions of leaves linear, acute; peduncles 1-5 cm. long; involucre of a few linear acute bractlets with the margins scarious and usually callous-toothed; rays 3 to 7, divaricate, subequal, 5-35 mm. long; pedicels 1 to 6, to 3 cm. long or the central flower of each umbellet sessile; fruit 1.5-2 mm. long, about 1.5 mm. broad, tuberculate. Swamps and moist woodlands in the Timber Belt and Blackland Prairies, Apr.-June; from Va., s. to Fla., w. to Kan. and Tex.

2. *Spermolepis inermis* (DC.) Math. & Const. Plant slender, erect, to 6 dm. high; leaves oblong-ovate, to 5 cm. long and 4 cm. wide, ternately decomposed; ultimate divisions of leaves filiform, mucronulate; peduncles 2-7 cm. long; involucre of a few narrow callous-toothed to glabrous bractlets shorter than the pedicels; rays 5 to 11, erect, unequal, 1-13 mm. long; pedicels 1 to 6, to 6 mm. long, the central umbellets bearing 1 to 3 sessile or shortly pedicellate flowers; fruit 1.5-2 mm. long, about 1.5 mm. broad, tuberculate to smooth. *S. patens* (DC.) Robins. Widely distributed in sandy or gravelly soil, mostly in s. half of Tex., Mar.-May; from Ind. and Neb., e. to N.C., w. to N.M., s. to Miss., Tex. and n. Mex.

3. *Spermolepis echinata* (DC.) Heller, Plant low and often spreading, to 4 dm. high; leaves ovate, to 25 mm. long and 2 cm. wide, ternately decomposed; ultimate divisions of leaves filiform, mucronulate; peduncles to 65 mm. long; involucre of a few filiform callous-toothed to glabrous bractlets that are shorter than the pedicels; rays 5 to 14, suberect, unequal, 1-15 mm. long; pedicels 1 to 6, to 7 mm. long, the central sessile umbellets 1-flowered; fruit ovoid, 1.5-2 mm. long and broad, covered with short echinate bristles. Widely distributed and usually in sandy soil, mostly in w. Tex., Mar.-May; from Mo., e. to Fla., s. to La. and Tex., w. to s. Calif. and n. Mex.

28. TORILIS ADANS. HEDGE-PARSLEY

Plants erect or decumbent, caulescent, branching, pubescent, herbaceous, annual from slender taproots; leaves 1- to 2-pinnate or pinnately decomposed, the ultimate divisions narrow; inflorescence of capitate or open compound umbels, the sessile or pedunculate umbels lateral or terminal and lateral; involucre of a few small bracts or lacking; involucre of several linear or filiform bractlets; rays 6 to 12, spreading-ascending or obsolete, the spreading pedicels short or obsolete; flowers white, the calyx teeth evident to obsolete, the thick stylopodium conic; carpophore bifid at the apex or cleft above the middle; fruit ovoid or oblong, compressed laterally, tuberculate or prickly, the primary ribs filiform and setulose, the lateral ribs displaced onto the commissural surface, the secondary ribs hidden by the numerous glochidiate prickles or tubercles that occupy the entire interval; oil tubes solitary under the secondary ribs and 2 on the commissure, the seed face concave to shallowly sulcate; strengthening cells present in the primary ribs, absent from the secondary.

A genus of about 20 species, principally of the Mediterranean region.

- 1. Umbels sessile or short-pedunculate, capitate, opposite the leaves1. *T. nodosa*.
- 1. Umbels usually long-pedunculate, spreading, terminal and lateral2. *T. arvensis*.

1. *Torilis nodosa* (L.) Gaert. **KNOTTED HEDGE-PARSLEY.** Plants to 6 dm. high, hispid throughout; leaves oblong, pinnately decomposed, ultimate divisions of leaves filiform, 2-8 mm. long, 1-2 mm. broad, acute, entire or pinnately lobed; peduncles much shorter than the leaves, to 25 mm. long to obsolete; involucre absent or of an inconspicuous linear bract; involucre of linear acute bractlets longer than the pedicels; rays few, short to obsolete; pedicels very short; fruit ovoid, 3-5 mm. long, 1-2 mm. broad, the outer mericarps bristly, the inner mericarps merely warty or sometimes only the outer part of the mericarp bristly. In moist places chiefly in the Timber Belt and the Blackland and Coastal prairies, Apr.-June; this Old World species is adv. in the W. Hemis.

This plant can become an extremely noxious pest in lawns.

2. *Torilis arvensis* (Huds.) Link. Plants slender, hispid throughout, the branches ascending; leaves ovate to ovate-lanceolate, 2- or 3-pinnate; leaflets ovate to linear-lanceolate, acute or acuminate, regularly incised or divided; peduncles 2-12 cm. long, longer than the leaves; involucre wanting; involucre of several subulate bractlets longer than the pedicels; rays 2 to 10, subequal to somewhat unequal, 5-25 mm. long; pedicels 1-4 mm. long; fruit ovoid-oblong, 3-5 mm. long, 2-3 mm. broad, the mericarps densely covered with uncinat bristles about as long as the width of the fruit. Chiefly in the Blackland Prairies and the Edwards Plateau, Apr.-June; adv. from the Old World.

29. DAUCUS L. CARROT

Plants erect, caulescent, branching, pubescent, herbaceous, annual or biennial from taproots; leaves pinnately decomposed, the ultimate divisions small and narrow; inflorescence of compound umbels that may become subcompact by the incurving of the rays after anthesis, the peduncles terminal and axillary; involucre of numerous dissected or entire bracts or lacking; involucre of numerous toothed or entire bractlets or lacking; rays few to numerous, spreading or the outer connivent over the shorter inner ones, the spreading pedicels unequal; flowers white or the central flower of each umbellet purple or rarely all reddish or yellow, the outer petals often radiant, the calyx teeth obsolete to evident, the stylopodium conic; carpophore entire or bifid at the apex; fruit oblong to ovoid, flattened dorsally, the bristly primary ribs filiform, the secondary ribs winged, the wings divided into a single row of barbed or glochidiate prickles; oil tubes solitary under the secondary ribs and 2 on the commissure, the seed face shallowly concave to nearly plane.

A nearly cosmopolitan genus of 50 to 60 species.

- 1. Bracts pinnately divided into short linear or lanceolate divisions; rays usually 4-40 mm. long; carpel usually broadest below the middle; central flower of umbellet white 1. *D. pusillus*.
- 1. Bracts pinnately divided into elongate filiform divisions; rays 30-75 mm. long; carpel broadest at the middle; central flower of umbellet rose or purple 2. *D. Carota*.

1. *Daucus pusillus* Michx. **RATTLESNAKE-WEED.** Plant annual, to 9 dm. high; stems usually solitary, simple or few-branched above, retrorsely papillate-hispid; leaves oblong, to 10.5 cm. long and 7 cm. wide; ultimate divisions of leaves linear, acute, hispid; peduncles 11-45 cm. long, retrorsely papillate-hispid; involucre of foliaceous pinnately decomposed bracts, with the short divisions linear to lanceolate; involucre of linear acute bractlets about equaling the pedicels; rays few to numerous, unequal, 4-40 mm. long, compact in fruit; pedicels unequal, 2-9 mm. long; flowers white; fruit oblong, 3-5 mm. long, about 2 mm. broad, usually broadest below the middle, the commissural surface with 2 rows of hispidulous hairs. Widespread almost throughout Tex., especially in the e. portion, commonly in disturbed soil, Apr.-May; across s. U.S. n. to B.C. and in n. Mex. and temp. S.A.

2. *Daucus Carota* L. **WILD CARROT, QUEEN ANNE'S LACE.** Plant biennial, 1.5-12 dm. high; stems solitary, glabrous to retrorsely hispid; leaves oblong, to 15 cm. long and 7 cm. wide; ultimate divisions of leaves linear to lanceolate, acute, mucronate, entire or few-cleft, glabrous to hispid especially on the veins and margins; divisions of the cauline leaves often elongate; peduncles 2.5-6 dm. long, retrorsely hispid; involucre of filiform elongate pinnately divided or rarely entire scarious-margined bracts 3-30 mm. long, usually

reflexed; involucre of linear acuminate entire or rarely pinnate more or less scarious ciliate bractlets that equal or exceed the flowers; flowers white (yellow or pinkish), the central flower of each umbellet purple or pinkish; fruit ovoid, 3-4 mm. long, about 2 mm. broad, broadest at the middle. Sporadic in waste places in the Blackland Prairies and the Rio Grande Plains, Apr.-May; widely distributed in the W. Hemis.; nat. of Euras.

30. CYMPTERUS RAF.

Plants low, acaulescent or subcaulescent, glabrous or pubescent, herbaceous, perennial from slender to thickened or fusiform taproots; leaves membranaceous to subcoriaceous or somewhat fleshy, green to pallid and glaucescent, ternate, digitate, pinnate or bipinnate to pinnately or ternate-pinnately decomposed; leaflets or ultimate divisions variously toothed or lobed to entire, usually narrow; inflorescence of compound umbels, the peduncles terminal and longer or shorter than the leaves; involucre lacking or present, the bracts scarious or foliaceous; involucre usually conspicuous, dimidiate, the bractlets foliaceous to scarious; rays few and spreading or abortive, the spreading pedicels slender to abortive; flowers white, yellow or purple, the calyx teeth small or obsolete, the stylopodium lacking; carpophore divided to the base; fruit ovoid to oblong, flattened dorsally, glabrous to pubescent, the lateral and usually one or more of the dorsal ribs broadly winged with the wings membranaceous to spongy-corky and broader or narrower than the body; oil tubes 1 to numerous in the intervals, 2 to numerous on the commissure and sometimes solitary at the base of the wings, the seed face concave to sulcate; strengthening cells absent or present.

A western North American genus of about 32 species.

1. Flowers yellow; bractlets of the involucre subscarious to foliaceous, not prominently nerved 1. *C. Fendleri*.
1. Flowers white to purple; bractlets of the involucre scarious, prominently nerved, sometimes connate (2)
- 2(1). Mature peduncles shorter than or equaling the leaves; fruit wings conspicuously enlarged at the base 2. *C. montanus*.
2. Mature peduncles equaling or exceeding the leaves; fruit wings not conspicuously enlarged at the base (3)
- 3(2). Bractlets lacerate-fringed at the apex 3. *C. macrorhizus*.
3. Bractlets entire or obtusely lobed at apex (4)
- 4(3). Bractlets white or whitish, few-nerved; pedicels 3-12 mm. long 4. *C. bulbosus*.
4. Bractlets purple or greenish, conspicuously many-nerved; pedicels less than 1 mm. long to obsolete 5. *C. multinervatus*.

1. *Cymopterus Fendleri* Gray. Plant acaulescent or subcaulescent, not cespitose, with the development of a pseudoscape 4-30 cm. high, the mature pseudoscape 1-3 cm. long, glabrous; leaves ovate to oblong-obovate, to 75 mm. long and 6 cm. wide, pinnate to bipinnate, green; leaflets longer than broad, entire to pinnately lobed, with obtuse or occasionally acute lobes; peduncles usually equaling or exceeding the leaves; involucre usually a low sheath, sometimes with 1 to 3 linear bracts; involucre of subscarious to foliaceous linear to ovate-oblong acute and frequently 3-toothed bractlets that equal or exceed the flowers; umbels compact, the fertile rays usually 3 to 5, to 25 mm. long, the central sterile umbellet sessile; pedicels obsolete; flowers yellow; fruit ovoid to ovoid-oblong, 5-13 mm. long, 4-10 mm. broad, the wings narrowed at the base and sometimes acuminate at the apex and about half as broad as the body, the dorsal wings 1 to 3 and similar to the lateral wings; oil tubes 3 to 16 in the intervals, 6 to 12 on the commissure, sometimes solitary at the wing base. In the Trans-Pecos and Plains Country, Mar.-Apr.; from Tex. to Colo., n. Ut., N.M. and Ariz.

2. *Cymopterus montanus* T.&G. Plant acaulescent or subcaulescent from long fusiform or subfusiform roots, with the development of a pseudoscape to 3 dm. high; leaves ovate-oblong, to 8 cm. long and 6 cm. wide, pinnate to bipinnate or occasionally ternate-

bipinnate, somewhat fleshy, pallid, with the leaflets entire to pinnately lobed; leaflet lobes usually obtuse, mucronate, confluent, roughened on the margins and veins; peduncles shorter than or equaling the leaves, to 10 cm. long, minutely roughened throughout or only at the base of the umbel; involucre lacking or of a low inconspicuous sheath or of conspicuous linear-oblong bracts; involucre of conspicuous ovate-oblong mostly acute bractlets; bractlets sometimes lacerate toward the apex, white with a conspicuous green central nerve, usually shorter than the flowers, the umbels subcompact; fertile rays 3 to 6, slightly spreading, to 2 cm. long, glabrous or minutely hirtellous, the sterile rays short; pedicels 2-5 mm. long; flowers white or purple; fruit ovoid to ovoid-oblong, 5-12 mm. long, 4-10 mm. broad; fruit wings conspicuously enlarged at the base, narrowed toward the apex, twice as broad as the body; oil tubes 1 to 4 in the intervals, 2 to 6 on the commissure, accessory oil tubes occasionally present in the wings. *Phellopterus montanus* Nutt. In the Plains Country, Mar.-May; from Tex. to S.D., Wyo. and n. N.M.

3. *Cymopterus macrorhizus* Buckl. Plant acaulescent or subcaulescent from fusiform to subglobose roots, with the development of a pseudoscape to 2.5 dm. high; leaves ovate-oblong, to 65 mm. long and 3 cm. wide, pinnate to bipinnate, pallid, somewhat fleshy, the leaflets entire to pinnately lobed; leaflet lobes obtuse, usually mucronate, confluent, sometimes minutely roughened on the margins; peduncles longer than the leaves, to 17 cm. long, usually minutely roughened at the base of the umbel; involucre lacking or of one or more linear bracts; involucre of conspicuous subcuneate bractlets lacerate-fringed at the apex, the bractlets white with a dark central nerve and usually shorter than the flowers; fertile rays 1 to 6, spreading, to 3 cm. long, glabrous or slightly roughened, the inner umbellets usually sessile and sterile, the sterile rays 5-10 mm. long, the sessile inner flowers sterile; pedicels 2 mm. long; flowers pinkish; fruit ovoid to ovoid-oblong, 4-9 mm. long, 3-8 mm. broad, the linear wings about equaling the body; oil tubes 3 to 8 in the intervals, 4 to 10 on the commissure, accessory tubes occasionally present in the wing base. *Phellopterus macrorhizus* (Buckl.) Coult. & Rose. Mostly in limy soil of the Blackland Prairies, the Plains Country and the Edwards Plateau in Tex. and adj. Okla., Mar.-May.

4. *Cymopterus bulbosus* A. Nels. Plant acaulescent or subcaulescent with the development of a pseudoscape to 35 cm. high, from long slender to clavate taproots, glabrous; leaves ovate-oblong, to 9 cm. long and 7 cm. wide, pinnate to bipinnate, pallid, somewhat fleshy, the leaflets entire to pinnately lobed; leaflet lobes obtuse, linear, confluent; peduncles usually several and exceeding the leaves, to 25 cm. long; involucre conspicuous, varying from a low sheath to conspicuous connate whitish 1- to 3-nerved bracts; involucre similar to the involucre, equaling or exceeding the flowers; fertile rays 3 to 8, spreading, to 3 cm. long, the sterile rays short; pedicels 3-12 mm. long; flowers purplish; fruit ovoid-oblong to oblong, 7-17 mm. long, 4-12 mm. broad; wings of fruit narrow or slightly enlarged at the base, narrower to broader than the body, acute; oil tubes 1 to 9 in the intervals, 3 to 10 on the commissure. Only in the Plains Country, spring; from Tex. to e. Ut., s.w. Wyo. and Ariz.

5. *Cymopterus multinervatus* (Coult. & Rose) Tidest. Plants acaulescent or subcaulescent, with the development of a pseudoscape to 2 dm. high, with long slender or subfusiform taproots; leaves ovate-oblong, to 85 mm. long and 6 cm. wide, pinnate to bipinnate or occasionally ternate-pinnate, somewhat fleshy, pallid, the leaflets entire to pinnately lobed; leaflet lobes acute or obtuse, mucronulate, usually confluent, glabrate; peduncles equaling or exceeding the leaves, 2-14 cm. long, glabrous; involucre a low scarious sheath or of 1 or 2 conspicuous nerved bracts, sometimes a conspicuous purplish connate cup with irregular many-nerved lobes; involucre of conspicuous ovate to ovate-oblong subconnate many-nerved greenish or purple bractlets, usually with a whitish margin and about equaling the flowers; umbels compact, the 1 to 5 glabrous fertile rays usually 5-25 mm. long, the inner rays shorter and the umbellets usually sterile, the sterile rays short; pedicels less than 1 mm. long; flowers purplish; fruit ovoid to ovoid-oblong, 8-17 mm. long and broad, frequently purplish-tinged, the long slender wings slightly enlarged at the base and twice to thrice as broad as the body; oil tubes 3 to 9 in the intervals, 5 to 12 on the commissure, accessory tubes occasionally present in the wings. Only in the Trans-Pecos, spring; from Tex. to s. Ut., s. Nev., s.e. Calif. and n. Mex.

31. PSEUDOCYMOPTERUS COULT. & ROSE

Plants slender to low, erect, subcaulescent to caulescent, glabrous to pubescent, herbaceous, perennial from long slender taproots; leaves 1- to 3-pinnate to ternate-pinnately decomposed, the leaflets or ultimate divisions filiform to obovate; inflorescence of compound umbels, the peduncles terminal and sometimes axillary, exceeding the leaves, conspicuously hirtellous-pubescent at the base of the umbels and occasionally on the rays; involucre usually lacking; involucre dimidiate, of oval to filiform bractlets free to connate at the base, longer or shorter than the flowers; rays few, spreading to ascending, subequal to unequal, the pedicels spreading; flowers yellow or purple, the ovate to deltoid calyx teeth evident, the stylopodium lacking; carpophore divided to the base; fruit ovoid to ovoid-oblong, flattened dorsally, glabrous, the lateral ribs broadly spongy-winged or membranous, linear to triangular in cross section, almost equaling the body, one or more dorsal ribs similarly winged (or all reduced to conspicuous ribs, or obsolete); oil tubes solitary to several in the intervals, 2 to several on the commissure, rarely also at the base of the wings, the seed face more or less plane; strengthening cells absent or present.

A highly variable genus of the western United States and adjacent Mexico, with at least two discrete species.

1. Leaves pinnately decomposed; rays 10-20 mm. long, ascending; fruit 3.5-5 mm. long
..... 1. *P. montanus*.
1. Leaves ternate-pinnately decomposed; rays 17-58 mm. long, spreading; fruit 6-9 mm.
long 2. *P. longiradiatus*.

1. *Pseudocymopterus montanus* (Gray) Coult. & Rose. MOUNTAIN PARSLEY. Plant to 85 cm. high; leaves ovate-oblong to broadly ovate; blades 1- to 3-pinnate, to 17 cm. long and 14 cm. wide, the ultimate divisions filiform to broadly lanceolate, acute, remote or more or less confluent; peduncles 14-30 cm. long; involucre of several acute bractlets 2-8 mm. long, connate at the base; rays 4 to 18, ascending, 10-20 mm. long, often scaberulous; pedicels 1-3 mm. long; fruit 3.5-5 mm. long, 1.5-2.5 mm. broad; oil tubes small, 1 to 3 in the intervals, 3 to 6 on the commissure. Usually in rocky places at 6,000-8,000 ft. alt. in the mts. of the Trans-Pecos, reported only from Mt. Livermore, July-Aug.; n. to Wyo. and w. to Ut. and Ariz., southw. into Mex.

Material from western Texas and adjacent Mexico, now referred to this species, may warrant recognition as a distinct taxon. However, more collections, particularly of fruiting material, and additional field studies are needed in order to define the nature of variability in this highly polymorphic species.

2. *Pseudocymopterus longiradiatus* Math., Const. & Theobald. Plant 3-9 dm. tall, caulescent with 1 to 3 stem leaves, rarely acaulescent; leaves ovate-oblong to broadly ovate, 4.5-15 cm. long, 3.5-13 cm. broad, ternate-pinnately decomposed, the ultimate divisions ovate to oblong, pinnately lobed to parted with the lobes obovate to linear-oblong, acute to distinctly acuminate; peduncles 13-49 cm. long; rays 8 to 18, spreading, 17-58 mm. long; bractlets of involucre linear-lanceolate, 3-11 mm. long, free to slightly connate at base; pedicels 2-6 mm. long; fruit 6-9 mm. long, 3-5 mm. broad; oil tubes large, solitary in the intervals, 2 on the commissure. In shady, damp, sandy or rocky places in canyons in the mts. of the Trans-Pecos, Apr.-Aug.; also in adj. N.M.

32. OXYPOLIS RAF. HOG-FENNEL

Plants slender, erect, caulescent, glabrous, herbaceous, perennial from fascicled tubers; leaves simply pinnate to ternate or reduced to hollow acute septate phyllodes; leaflets (when present) broad or narrow, serrate to incised, mostly distinct and sessile; inflorescence of compound umbels, the peduncles terminal and axillary; involucre of a few slender bracts or lacking; involucre similar to the involucre or lacking; rays few to numerous, usually spreading-ascending, the slender pedicels ascending to spreading; flowers white or purple, the calyx teeth prominent or minute, the stylopodium conic; carpophore divided to the base; fruit oblong to obovoid, strongly flattened dorsally, glabrous, the dorsal ribs filiform, the lateral broadly thin-winged and nerved dorsally at the inner margin to give the appearance of 5 filiform dorsal ribs; oil tubes large, solitary in the

intervals, 2 to 6 on the commissure, the seed face plane; strengthening cells beneath the dorsal ribs and the nerves of the lateral wings.

A genus of about half a dozen species, chiefly of the eastern and southeastern United States.

- 1. Leaves reduced to cylindrical or flattened entire septate phyllodes; rays 8 to 14 1. *O. filiformis*.
- 1. Leaves pinnate, the leaflets broad or narrow; rays 15 to 45 2. *O. rigidior*.

1. *Oxypolis filiformis* (Walt.) Britt. Plant to 14 dm. high; leaves reduced to hollow septate phyllodes 2-6 dm. long; peduncles 2-9 cm. long; involucre of several linear to lanceolate bracts 5-15 mm. long; involucre of linear to lanceolate bractlets 2-4 mm. long; rays 8 to 14, spreading, slightly unequal, 2-4.5 cm. long; pedicels spreading, 5-10 mm. long; calyx teeth conspicuous; fruit oval or obovoid, 5-8 mm. long, 3-5 mm. broad, the lateral wings thinner than the body. Wet places in the Timber Belt and the Blackland and Coastal prairies, July-Sept.; from Va. s. to Fla. and w. to Tex.; also Bah. I. and Cuba.

2. *Oxypolis rigidior* (L.) Raf. COWBANE, WATER-DROPWORT. Plant 6-15 dm. high; leaves oval to triangular or lanceolate, to 30 cm. long and 25 cm. wide, pinnate; leaflets 5 to 9, lanceolate or linear, remotely salient-dentate or entire; peduncles 6-30 cm. long; involucre of a few linear bracts 1-2 cm. long; involucre of a few linear bractlets 3-5 mm. long; rays 15 to 45, spreading, subequal, 3-12 cm. long; pedicels spreading, 5-15 mm. long; calyx teeth conspicuous; fruit oval or oblong, 4-7 mm. long, 2.5-4 mm. broad. Along streams and in other wet places in the Timber Belt and the Blackland and Coastal prairies, Aug.-Oct.; from N.Y., s. to S.C., w. to Minn. and Tex.

33. POLYTAENIA DC.

Plants stout, erect, caulescent, branching, puberulent, herbaceous, perennial from subfusiform taproots; leaves bipinnate or ternate-pinnate, with large crenate to incised or lobed leaflets; inflorescence of compound umbels, the terminal and lateral peduncles exceeding the leaves; involucre lacking; involucre of several linear to filiform entire puberulent bractlets shorter than the flowers; rays rather few, spreading-ascending, puberulent, the puberulent pedicels spreading-ascending; flowers yellow, the calyx teeth ovate and acute or acuminate, the stylopodium lacking; carpophore divided to the base; fruit broadly oval to orbicular or obovate, strongly flattened dorsally, glabrous, the dorsal ribs filiform to obscure, the lateral ribs corky-winged; oil tubes distinct or indistinct, solitary or several in the intervals, 2 to several on the commissure and scattered throughout the pericarp, the seed face plane.

A genus of 2 species, in the central and south-central United States.

- 1. Fruit 5-11 mm. long, 4-7 mm. broad, the lateral wings narrower and thicker than the body; oil tubes indistinct, several in the intervals . . . 1. *P. Nuttallii*.
- 1. Fruit 9-11 mm. long, 6-7 mm. broad, the lateral wings broader and thinner than the body; oil tubes distinct, solitary in the intervals 2. *P. texana*.

1. *Polytaenia Nuttallii* DC. PRAIRIE-PARSLEY. Plant 5-10 dm. high, puberulent (especially in the inflorescence); leaves oblong to ovate, to 18 cm. long and 15 cm. wide, bipinnate or ternate-pinnate; leaflets sessile, distinct or the terminal confluent, ovate to oblong, obtuse at the apex, rounded or cuneate at the base; upper cauline leaves ternate with conspicuously dilated sheaths; peduncles 2-10 cm. long; bractlets 2-5 mm. long; rays 10 to 20, to 6 cm. long, subequal to unequal; pedicels 3-5 mm. long; fruit 5-11 mm. long, 4-7 mm. broad, the dorsal ribs filiform to obscure, the lateral narrowly corky-winged with the wings narrower and thicker than the body; oil tubes indistinct, several in the intervals and on the commissure. *Pleiotaenia Nuttallii* (DC.) Coult. & Rose. In sandy soil in the Timber Belt and the Blackland Prairies, Mar.-June; from Tex. and La., n. to Ky., Mich. and Ia.

2. *Polytaenia texana* (Coult. & Rose) Math. & Const. TEXAS-PARSLEY. Plant 5-8 dm. high; leaves ovate to oblong, to 13 cm. long and 10 cm. wide, ternate-pinnate; leaflets sessile, distinct or confluent, broadly ovate to oblong, obtuse at the apex, cuneate at the

base; upper cauline leaves ternate with broadly cuneate divisions; peduncles 1-5 cm. long; bractlets 2-5 mm. long; rays 10 to 15, subequal, 1-2.5 cm. long; pedicels 2-6 mm. long; fruit 9-11 mm. long, 6-7 mm. broad, the dorsal ribs filiform, the lateral broadly corky-winged with the wings broader but thinner than the body; oil tubes distinct, solitary in the intervals, 2 on the commissure. *Pleiotænia Nuttallii* var. *texana* Coult. & Rose. Abundant on the Blackland and Coastal prairies and the Edwards Plateau, Apr.-July; endemic.

34. PASTINACA L.

A genus of about 15 species of boreal Eurasia, closely related to *Heracleum*.

1. *Pastinaca sativa* L. GARDEN PARSNIP, WILD PARSNIP. Plant erect, biennial or perennial from taproots, 3-10 dm. high; leaves pinnately compound, oblong to ovate, to 25 cm. long and 15 cm. wide, cordate; leaflets oblong to ovate, coarsely serrate and lobed or divided, puberulent or glabrate; cauline leaves with conspicuously dilated sheaths; peduncles stout, terminal and lateral, 7-15 cm. long; involucre and involucel lacking; rays 15 to 25, unequal, spreading-ascending, to 10 cm. long; pedicels spreading, 5-10 mm. long; petals yellow; calyx teeth minute or obsolete, the stylopodium depressed-conic; carpophore divided to the base; fruit orbicular to obovate, 5-6 mm. long, 4-5 mm. broad, strongly flattened dorsally, glabrous, the dorsal ribs filiform, the lateral ribs broadly thin-winged and nerved near the outer margins; oil tubes large, solitary in the intervals and 2 to 4 on the commissure, the seed face plane; strengthening cells in the dorsal ribs and near the outer wing-margins. The cult. parsnip has been reported as adv. in the Trans-Pecos; a Eur. species widely naturalized in the U.S., Can. and W.I.

35. LOMATIUM RAF.

The largest western North American genus in the family with about 80 species.

1. *Lomatium daucifolium* (Nutt.) Coult. & Rose. Plant acaulescent, to 45 cm. high, perennial with a long usually swollen taproot, villous-tomentose to glabrate; leaves broadly ovate to obovate, to 19 cm. long, ternate, then 3- to 4-pinnate; ultimate divisions of leaf linear, crowded, entire, apiculate; peduncles usually terminal, exceeding the leaves; involucre usually lacking; involucel of subdimidiate lanceolate acute to acuminate subscurious bractlets that are conspicuously nerved and connate to above the middle, equaling the flowers; rays 12 to 30, erect to spreading, to 7 cm. long, subequal; pedicels slender, to 13 mm. long, the umbellets 20- to 40-flowered, the central flowers often sterile; flowers yellow, the calyx teeth obsolete or small, the stylopodium lacking; carpophore divided to the base; fruit ovate-oblong, 6-9 mm. long, 3-6 mm. broad, flattened dorsally, glabrous, the dorsal ribs filiform or obsolete, the lateral ribs with membranaceous or corky wings narrower than the body; oil tubes 1 to 3 in the intervals, 2 to 4 on the commissure, occasionally solitary near the base of each wing, the seed face plane to slightly concave. In the n. Blackland Prairies and Plains Country, Mar.-Apr.; from Tex. n. to S.D.

36. EURYTAENIA T. & G.

Plants slender, erect, caulescent, branching, scaberulous, herbaceous, annual from slender taproots; basal leaves lobed or pinnatifid with obtuse crenate-serrate lobes, the cauline leaves pinnately or ternate-pinnately dissected with narrow often elongate entire or serrate divisions; inflorescence of compound umbels, the peduncles terminal and lateral; involucre of 1- to 2-ternate reflexed bracts shorter than the rays; bractlets like the bracts or entire; rays few, spreading-ascending, unequal, scaberulous, the slender pedicels spreading-ascending and scaberulous; flowers white, the calyx teeth prominent, the stylopodium depressed; carpophore divided to the base; fruit oblong-oval to orbicular, strongly flattened dorsally, scaberulous to glabrous, the dorsal ribs filiform to narrowly winged, the lateral ribs broadly winged, the wings nerved near the middle and with their margins contiguous; oil tubes large and flattened, solitary in the intervals and 2 on the commissure, the seed face plane; strengthening cells prominent in the ribs.

A genus of 2 species, endemic to Texas and Oklahoma.

1. Fruit oval to orbicular, 4-6 mm. long and broad, the lateral wings thin and lighter-colored than the body1. *E. texana*.
1. Fruit oblong-oval, 5-8 mm. long, 4-5 mm. broad, the lateral wings thicker than and homochromous with the body2. *E. Hinckleyi*.

1. *Eurytaenia texana* T.&G. TEXAS SPREAD-WING. Plant 3-12 dm. high, scaberulous in the inflorescence or glabrate; leaves ovate, to 10 cm. long and 5 cm. wide, lobed or pinnatifid with obtuse crenate or serrate lobes; cauline leaves pinnately or ternate-pinnately dissected; divisions of leaf oblong-lanceolate to linear or filiform, sharply serrate to entire, the terminal ones often elongate; peduncles 4-15 cm. long; involucre of about 5 usually 3-cleft bracts that are to 1 cm. long and scarious-margined toward the base; involucre of several bractlets like the bracts or entire; rays 8 to 15, spreading-ascending, 1.5-8 cm. long; pedicels 5-8 mm. long; fruit oval to orbicular, 4-6 mm. long and broad, scaberulous to glabrous, emarginate at the apex, the dorsal ribs filiform, the thinner lateral wings broader and lighter-colored than the body, distinctly nerved only on the commissural surface, their margins tapering gradually. Sandy soil in the Coastal and Blackland prairies, the Rio Grande Plains, and the Plains Country, Apr.-June; also Okla.

2. *Eurytaenia Hinckleyi* Math. & Const. Vegetatively very similar to *E. texana*; fruit oblong-oval, 5-8 mm. long, 4-5 mm. broad, scaberulous, truncate or emarginate at the apex, the dorsal ribs very narrowly winged, the lateral wings thicker than and homochromous with the body, prominently carinate-nerved on the dorsal surface; mericarps appearing 5-ribbed, their margins abruptly narrowed to a thin bordering flange. On white (perhaps gypsum) sands in the extreme s.w. Plains Country and adj. Trans-Pecos, May-July; endemic.

37. ANETHUM L.

A western Asiatic genus of 2 species.

1. *Anethum graveolens* L. DILL. Plant slender, 4-17 dm. high, erect, caulescent, alternately branching above, glabrous and glaucous, herbaceous, with a strong anise-odor, annual from subfusiform roots; leaves oblong to obovate, to 35 cm. long and 20 cm. wide, pinnately dissected with filiform divisions; upper cauline leaves greatly reduced; inflorescence of compound umbels, the terminal and lateral peduncles 7-16 cm. long and exceeding the leaves; involucre and involucre usually lacking; rays 10 to 45, spreading, 3-10 cm. long; pedicels 20 to 50, slender and spreading, 6-10 mm. long; flowers yellow, the calyx teeth obsolete, the stylopodium conic; carpophore divided to the base; fruit ovoid, about 4 mm. long and 2 mm. broad, flattened dorsally, glabrous, the ribs narrowly winged, the lateral ones broader than the dorsal; oil tubes solitary in the intervals, 2 to 4 on the commissure; seed face plane or slightly concave. Adv. primarily in Rio Grande Plains, sporadic elsewhere, Apr.-May; nat. to the Old World and adv. throughout warmer parts of the New World.

38. SANICULA L. BLACK SNAKEROOT. SANICLE

Plants low or slender, erect, spreading or decumbent, herbaceous, caulescent or acaulescent, branching, glabrous or pubescent, biennial or perennial from taproots, rootstocks, tubers, or fascicled fibrous roots; leaves petiolate to sessile, palmately or pinnately divided to pinnately or ternate-pinnately decomposed, rarely entire, the divisions variously toothed to lobed or entire, the rachis naked or winged; inflorescence of irregularly arranged capitulate umbellets, the peduncles terminal or terminal and lateral; involucre of small or occasionally large entire or lobed bracts longer or shorter than the umbellets; rays spreading to obsolete; flowers white, greenish-white, greenish-yellow, yellow, or purple, perfect or staminate, the staminate flowers often prominently pedicellate, the connate sepals prominent and persistent; stylopodium lacking; fruit oblong-ovoid to subglobose or ellipsoid, somewhat compressed laterally, densely covered with uncinat bristles or tubercles or lamellae, the ribs obsolete; oil tubes large or small, irregularly

arranged, several to numerous on the dorsal and lateral surfaces, usually 2 on the commissure, the seed face plane to concave or sulcate; strengthening cells absent.

A nearly cosmopolitan genus (absent from Australia and New Zealand) of 35 to 40 species.

1. Fruits sessile; plant from fascicled tuberous roots3. *S. Smallii*.

1. Fruits pedicellate or stipitate; plants from fascicled fibrous roots (2)

2(1). Styles exerted in fruit; flowers greenish-yellow; calyx deeply cleft, the lobes much shorter than the petals1. *S. gregaria*.

2. Styles included in fruit; flowers white; calyx cleft to the middle, the lobes exceeding the petals2. *S. canadensis*.

1. *Sanicula gregaria* Bickn. Plant erect, 2-7.6 dm. high, perennial from slender fascicled fibrous roots, glabrous, the stems solitary or several from the base and dichasially branched above; leaves broadly triangular to ovate, to 12 cm. long and 20 cm. wide, palmately 3- to 5-parted; primary divisions of leaf cuneate-obovate to lanceolate, acute, petiolulate, distinct or the lateral somewhat united, sharply serrate to incised-lobed above with spinulose teeth; cauline leaves few, similar; involucre of inconspicuous subscarious bracts; umbels few-flowered; sterile and fertile flowers in the same umbellet or the sterile in separate peduncled heads in the axils of the stem or main branches; fertile rays about 2 mm. long; flowers greenish-yellow; calyx cleft to the middle, the triangular-ovate lobes subobtusate with an inconspicuous central nerve and much shorter than the petals; anthers bright-yellow, exerted; styles conspicuous, recurved, exceeding the bristles; fruits usually 3 in each umbellet, subglobose to obovoid, 3-5 mm. long, 2-3 mm. broad, distinctly stipitate, minutely bristly or papillose, the numerous bristles not crowded and arranged in rows, conspicuous above but rudimentary below; oil tubes small, solitary in the intervals, 2 or 3 on the commissure; seed face plane, the scar linear. In moist woods in the Timber Belt and Blackland Prairies, Apr.-May; from Que., s. to Fla., w. to S.D. and Tex.

2. *Sanicula canadensis* L. Plant erect, to 10 dm. high, biennial from fibrous woody roots, glabrous, the usually solitary stem alternately dichotomously branched above and 3- to 4-furcate at the apex; leaves triangular to suborbicular, to 14 cm. long and 16 cm. wide, palmately 3-parted (occasionally 5-parted or appearing so by division of the lateral primary divisions); primary divisions of leaf ovate-lanceolate to cuneate-obovate, obtuse to acute, distinct, closely serrate and sometimes deeply incised above, the teeth mucronate to spinulose; cauline leaves becoming sessile above; involucre of a few small leaflike bracts; umbels few-flowered; sterile and fertile flowers in the same umbellet, the sterile flowers shortly radiate; rays 1-2 mm. long; flowers white; calyx deeply cleft, the narrowly lanceolate lobes acute and exceeding the petals; anthers white, slightly exerted; styles shorter than the calyx, inconspicuous; fruits 3 in each umbel, globose, 2-5 mm. long and broad, wrinkled, striate, the bristles dilated below, numerous in longitudinal rows, well-developed throughout; oil tubes large, solitary in the grooves of the dorsal surface, 2 on the commissure; seed face convex, the scar linear. In moist woods throughout e. and cen. Tex., Apr.-June; from Vt., s. to Fla., w. to S.D. and Tex.

3. *Sanicula Smallii* Bickn. Plant erect, 33-64 cm. high, biennial or perennial from fascicled tuberous roots, glabrous, the usually solitary stem occasionally alternately branched and 2- to 3-furcate above; leaves ovate, to 8 cm. long and 14 cm. wide, palmately 3-parted (appearing 5-parted by division of the lateral primary divisions); primary divisions of leaf ovate-lanceolate, acute, distinct, closely and regularly serrate, the teeth mucronate; cauline leaves becoming sessile above; involucre of small triangular-ovate subacuminate bracts; umbels few-flowered; sterile and fertile flowers in the same umbellet, the sterile flowers shortly radiate; fertile rays obsolete; flowers white; calyx deeply cleft, the rigid linear-subulate lobes with a conspicuous central nerve and about equaling the petals; anthers exerted; styles equaling or exceeding the calyx, shorter than the bristles; fruits usually 3 in each umbel, sessile, subglobose to ovoid, 3-5 mm. long, about 3 mm. broad, the numerous bristles short below and exceeding the erect calyx lobes above; oil tube large, solitary in the intervals, 2 or 3 on the commissure; seed face usually concave, the scar broadly linear. In moist woodlands in the Timber Belt, Apr.-May; from N.C., s. to Fla., w. to Mo. and Tex.

39. ERYNGIUM L. ERYNGO

Plants creeping to erect, caulescent or acaulescent, usually glabrous, herbaceous, annual, biennial or perennial from stout taproots or rootstocks bearing fibrous roots; leaves coriaceous or membranaceous, entire to pinnately or palmately lobed to divided, often ciliate to spinose, the venation parallel or reticulate, the petioles sheathing and sometimes septate; inflorescence capitate, the heads solitary or in cymes or racemes; involucre of one or more series of entire or lobed bracts subtending the head; involucel of entire or lobed bractlets subtending the flowers; flowers white to purple, sessile; sepals ovate to lanceolate, obtuse to acute, entire or rarely spinescent, persistent; stylopodium lacking; carpophore lacking; fruit globose to obovoid, scarcely compressed laterally, variously covered with scales or tubercles, the ribs obsolete, the commissure broad; oil tubes mostly 5, inconspicuous; seed face plane or slightly concave.

A genus of more than 200 species, in the temperate and warmer parts of the world, with important centers of development in Brazil-Paraguay, Mexico, western Asia, the Mediterranean region, and southeastern and western United States.

- 1. Leaves parallel-veined; plants with a monocotyledonous habit (2)
- 1. Leaves reticulate-veined; plants not monocotyledonoid (3)
- 2(1). Leaves 10-30 mm. broad, the marginal setae usually solitary; bracts ovate-lanceolate1. *E. yuccifolium* var. *yuccifolium*.
- 2. Leaves 5-10 mm. broad, the marginal setae usually in groups of 2 to 4; bracts linear-lanceolate2. *E. yuccifolium* var. *synchaetum*.
- 3(1). Cauline leaves conspicuously spinulose-pungent; bracts mostly broad, variously spinose-toothed, rarely entire, pungent (4)
- 3. Cauline leaves entire to pinnatifid, not spinulose-pungent; bracts very narrow, sometimes pungent-tipped, entire or occasionally with 3 to 5 spiny teeth (7)
- 4(3). Heads large, 2-3.5 cm. long, bright purple to red; bractlets spinescent with 3 to 7 prominent teeth; coma of about 8 prominent spinescent bracts 1-2 cm. long5. *E. Leavenworthii*.
- 4. Heads small, 2 cm. or less long; bractlets entire; coma-bractlets entire, inconspicuous or lacking (5)
- 5(4). Bracts bicolored, green or bluish beneath, yellowish-white above3. *E. heterophyllum*.
- 5. Bracts greenish above and below, not bicolored (6)
- 6(5). Plant diffusely branched; basal leaves deeply palmately parted, sessile or subsessile6. *E. diffusum*.
- 6. Plant erect; basal leaves serrate or dentate, petiolate ..7. *E. Hookeri*.
- 7(3). Plant erect; lower bractlets tricuspidate; basal leaves usually cordate8. *E. integrifolium*.
- 7. Plants prostrate to ascending; bractlets entire; basal leaves not cordate (8)
- 8(7). Heads in a terminal branched inflorescence, subsessile, many-flowered; bractlets exceeding the fruit4. *E. nasturtiifolium*.
- 8. Heads solitary, axillary, on filiform peduncles, few-flowered; bractlets shorter than the fruit9. *E. prostratum*.

1. *Eryngium yuccifolium* Michx. var. *yuccifolium*. RATTLESNAKE-MASTER, BUTTON SNAKE-ROOT. Plants stout, glabrous, 3-18 dm. high, perennial from a fascicle of tuberous woody roots; stems slender, solitary, branching above; basal leaves rigid, broadly linear, to 10 dm. long, 1-3 cm. wide, acute, remotely bristly with solitary (or occasionally 2 or more) bristles, the venation parallel; sheaths short; cauline leaves like the basal, reduced above; inflorescence cymosely branched, the pedunculate heads large, the flowers numerous; heads globose-ovoid, 1-2.5 cm. in diameter; bracts 6 to 10, spreading-ascending, ovate-lanceolate, to 15 mm. long, cuspidate, mostly entire, shorter than the

heads; bractlets like the bracts, entire or minutely serrulate, exceeding the fruit; coma wanting; sepals ovate, obtuse, mucronulate; styles exceeding the sepals; fruit oblong, 4-8 mm. long, the flattened scales of the angles lanceolate, 1.5-3 mm. long, those of the dorsal surfaces reduced or obsolete. In open prairies in the Timber Belt and the Coastal and Blackland prairies, May-Aug.; from Conn., s. to Fla., w. to Minn., Kan. and Tex.

2. *Eryngium yuccifolium* var. *synchaetum* Coult. & Rose. Plants slender; basal leaves to 35 cm. long and 1 cm. wide, remotely spinulose-setose, with the weak setae in groups of 2 to 4 and to 1 cm. long; heads subglobose, 1-1.5 cm. in diameter; bracts 6 to 9, spreading or reflexed, linear-lanceolate, to 1 cm. long, entire or few-toothed; bractlets like the bracts but broader, about 5 mm. long, entire, exceeding the fruit; sepals acute; petals oblong, 1.5 mm. long. *E. synchaetum* (Coult. & Rose) Coult. & Rose. In pine woodlands in the Timber Belt and in the Blackland and Coastal prairies, July-Aug.; from Ga. and Fla., w. to Tex. and Okla.

Var. *synchaetum* is distinguishable from var. *yuccifolium*, if at all, with difficulty; it may be an ecological variant, but it requires further study.

3. *Eryngium heterophyllum* Engelm. MEXICAN-THISTLE. Plants rather stout, caulescent, glabrous, 2-6 dm. high, perennial from a stout taproot, the stems erect and branching; basal leaves rosulate, narrowly oblanceolate to oblong-oval, to 12 cm. long and 3 cm. wide, cuneate, acute or obtuse, those of the sterile rosettes setose-dentate, the fertile leaves spinose-serrate to pinnatifid or bipinnatisect, the teeth or lobes acute, pungent, callous-margined, the venation pinnately reticulate; petioles narrowly winged, sheathing at the base, shorter than the blades; cauline leaves numerous, like the basal, the lower pinnatifid or bipinnatisect, the upper leaves opposite, sessile and palmately parted; inflorescence paniculately branched, the numerous pedunculate heads rather small, the flowers numerous; heads ovoid, blue to white, 7-15 mm. long, 5-10 mm. broad; bracts 8 to 14, rigid, spreading-ascending, linear-lanceolate to lanceolate, to 25 mm. long and 5 mm. wide, pungent or acuminate, with 1 or 2 pairs of spinose teeth or entire, green or bluish beneath and yellowish-white above, exceeding or occasionally shorter than the heads; bractlets subulate, 3-5 mm. long, entire, curved, exceeding the fruit; coma of 1 to 4 entire bractlets 5-15 mm. long or occasionally obsolete; sepals ovate, about 1 mm. long, obtuse or truncate and apiculate; styles slender, exceeding the sepals; fruit globose, 1.5-2.5 mm. in diameter, with flat scales below the sepals and on the upper angles, the faces papillate. In sandy soil in mts. of the Trans-Pecos, July-Sept.; from w. Tex., w. to Ariz., s. to Oax.

4. *Eryngium nasturtiifolium* Juss. HIERBA DEL SAPO. Plants prostrate, ascending or rarely erect, 1-3 dm. high or long, glabrous, biennial or perennial from a fascicle of fibrous roots or a slender taproot, the leafy stems several and branched from the base; basal leaves spatulate to oblanceolate, to 10 cm. long, 1-3 cm. wide, cuneate, coarsely dentate to runcinate-pinnatifid, the teeth or lobes mucronulate or spinose, the venation reticulate; petioles broad, winged; cauline leaves like the basal, spinose-dentate or spinose-pinnatifid; inflorescence divaricately trifurcate or cymose, the lateral branches often elongated and continuous to form a monochasium, the small heads numerous and nearly sessile, the flowers numerous; heads ovoid to ovoid-cylindric, to 15 mm. long and 8 mm. broad; bracts 5 to 9, rigid, spreading, subulate to linear-lanceolate, 8-20 mm. long, entire, pungent, about equaling the heads; bractlets lanceolate to obovate, 4-9 mm. long, broadly scarious-margined at the base, entire, exceeding the fruit; coma of several short bractlets 3-7 mm. long, resembling the bracts; sepals ovate, 1-1.5 mm. long, obtuse or acute, mucronulate, serrulate toward the apex; styles shorter than to exceeding the sepals; fruit ovoid-globose, 2-3 mm. long, densely covered with elliptic to linear white or flavescent scales to 2 mm. long. In moist heavy soil in the Rio Grande Plains, Mar.-July; Tex., Mex. and Cuba.

5. *Eryngium Leavenworthii* T.&G. Plants rather slender, glabrous and purplish, 5-10 dm. high, annual from a slender taproot, the leafy stems erect and divaricately branching; lower cauline leaves short-petiolate, broadly oblanceolate, to 6 cm. long and 2 cm. wide; upper cauline leaves sessile, broadly ovate to orbicular, deeply palmately parted, the divisions pinnatifid with pungent lobes, the venation reticulate; inflorescence sparingly cymose, the usually few short-pedunculate heads large, the flowers numerous; heads purplish to red, ovoid to ovoid-cylindric, to 35 mm. long and 25 mm. broad; bracts about

8, oblong, 3-4 cm. long, spinose-pinnatifid like the upper leaves, about equaling the heads; bractlets linear, 1 cm. long, spinose-lobed with 3 to 7 prominent teeth, exceeding the fruit; coma of about 8 prominent spinescent bractlets 1-2 cm. long; sepals oblong, 5 mm. long, spinose-pinnatifid toward the apex; styles shorter than the sepals; fruit oblong, 2-4 mm. long, densely covered on the angles and faces with linear or claviform white scales 1-2 mm. long. In plains and prairies throughout Tex. except in the Rio Grande Plains and the Trans-Pecos, July-Sept.; from Tex., n. to Kan.

6. *Eryngium diffusum* Torr. Plants low, caulescent, diffusely branched, prostrate to erect, 1-4 dm. high or long, glabrous, annual (?) from a slender taproot; basal leaves nearly sessile, obovate to cuneate, to 5 cm. long and 2 cm. wide, deeply palmately parted, the cuneate or oblong divisions spinulose-dentate or lobed, the venation palmately reticulate; cauline leaves numerous, like the basal; inflorescence successively trifurcate or some lateral branches elongated to form a monochasium, the small heads numerous and very short-pedunculate, the flowers numerous; heads bluish, globose-ovoid, 8-12 mm. long, 6-8 mm. broad; bracts 10 to 12, rigid, spreading, linear-lanceolate, 10-15 mm. long, 2-3 mm. wide, pungent, spinose-serrate, scarious-margined at the base, exceeding the heads; bractlets lanceolate, 5 mm. long, mucronate, entire, broadly scarious-winged at the base, exceeding the fruit; coma lacking; styles shorter than to slightly exceeding the sepals; fruit globose-ovoid, 2.5-3 mm. long, densely covered with linear acute subequal white scales 1-2 mm. long. In sandy soil almost throughout Tex. except in the Timber Belt and Trans-Pecos, May-Aug.; also in adj. Okla.

7. *Eryngium Hookeri* Walp. Plants slender, caulescent, glabrous, 3-6 dm. high, annuals from fascicled fibrous roots, the erect stems solitary and branched above; basal leaves obovate to oblong-lanceolate, 6-9 cm. long, 2-3 cm. wide, acute, somewhat serrate or dentate, the venation reticulate; petioles slender, sheathing at the base; lower cauline leaves nearly sessile, lanceolate, laciniately toothed and spinulose with a pair of small lacinate segments at the base; upper cauline leaves ovate, palmately divided with 5 to 7 oblong lacinate or pinnatifid spinulose lobes 2-3 cm. long; inflorescence cymosely branched, the pedunculate heads rather large, the flowers numerous; heads amethystine, ovoid to cylindrical-ovoid, 8-15 mm. in diameter; bracts numerous, rigid, linear-lanceolate, 1-2 cm. long, spinulose-serrate, broadly winged at the base, exceeding the heads; bractlets lanceolate, 4-6 mm. long, pungent, entire, exceeding the fruit; coma of a few elongate bractlets or wanting; sepals ovate-lanceolate, 2 mm. long, pungent-acuminate; styles shorter than the sepals; fruit 1-2 mm. long, densely covered with flat tawny scales to 0.5 mm. long. In moist limy soil in the Coastal and Blackland prairies, July-Sept.; also La.

8. *Eryngium integrifolium* Walt. Plants slender, caulescent, glabrous, 3-8 dm. high, perennial from a fascicle of tuberous or fleshy-fibrous roots, the erect stems solitary and branching above; basal leaves oblong-lanceolate to oblong-ovate, to 6 cm. long and 2.5 cm. wide, usually cordate at the base, obtuse, entire to shallowly crenate, the venation reticulate; petioles sheathing at the base, lower cauline leaves like the basal but short-petiolate to sessile, the uppermost leaves linear to oblanceolate or ovate, acute, usually spinulose-serrate or rarely lacinate or subentire; inflorescence branched, the pedunculate heads rather small, the flowers numerous; heads amethystine, ovoid to globose, 5-15 mm. in diameter; bracts 6 to 10, rigid, linear, 1-2 cm. long, entire or usually with 3 to 5 spiny teeth, exceeding the heads; bractlets tricuspidate, 3 mm. long, exceeding the fruit; coma lacking; sepals lanceolate, 1-1.5 mm. long, mucronate; styles slender, exceeding the sepals; fruit about 2 mm. long, the angles densely covered with rows of lanceolate white scales 0.5-1 mm. long, the surfaces usually scaleless. In moist woods and bogs in the Timber Belt and the Coastal and Blackland prairies, Aug.-Oct.; from N.C., s. to Fla. and w. to Tex. and Okla.

9. *Eryngium prostratum* DC. Plants low, prostrate or ascending, glabrous, 1.5-7 dm. high, perennial from a fascicle of fibrous roots, the stems very slender and simple or somewhat branched above; basal leaves ovate to lanceolate, to 55 mm. long and 25 mm. wide, simple or palmately lobed, the margins entire or irregularly and remotely dentate, the venation reticulate; petioles slender; cauline leaves like the basal, reduced, clustered at the nodes, sessile above; inflorescence of elongated monochasia bearing small numerous heads on filiform axillary peduncles, the flowers few; heads often blue, ovoid to ovoid-cylindric, to 9 mm. long and 4 mm. broad; bracts 5 to 10, foliaceous, reflexed, lanceolate,

to 12 mm. long, acute, equaling the heads; bractlets narrowly subulate, about 1 mm. long, acute, shorter than the fruit; coma lacking; sepals ovate to semiorbicular, about 0.8 mm. long, obtuse, mucronulate; styles exceeding the sepals; fruit subglobose, 2 mm. in diameter, sparsely covered with low white tubercles. In moist soil in the Timber Belt and the Coastal and Blackland prairies, May-Sept.; from S.C., s. to Fla. and w. to Ky., Mo. and Tex.

40. CENTELLA L.

A genus of perhaps 20 species, chiefly of the Southern Hemisphere.

1. *Centella asiatica* (L.) Urban. Plant perennial from slender creeping rootstocks, with stems 1 to several dm. long, rooting at nodes; leaves ovate-cordate to oblong, obtuse, to 10 cm. long and 9 cm. wide, entire or repand-toothed; petioles glabrous to fulvous-pubescent, usually with a tuft of hairs at the apex, to 35 mm. long, usually much shorter; inflorescence of simple lax to subcapitate umbels; peduncles axillary, shorter than to exceeding the leaves, to 11.5 cm. long; involucre of 2 conspicuous ovate to suborbicular scarious bracts; rays 2 to 5, to 4 mm. long; flowers white or rose-tinged, the calyx teeth obsolete, the stylopodium obsolete; carpophore entire; fruit ellipsoid, 3-4 mm. long, 3-5 mm. broad (broader than long), constricted at the commissure and flattened laterally, glabrous, the filiform primary ribs prominent, the secondary ribs and reticulations evident, the seed face plane; an oil-bearing layer beneath the epidermis, occasionally containing small oil tubes and a thick layer of strengthening cells surrounding the seed cavity. *C. erecta* (L. f.) Fern. Edges of streams and other wet places in e. half of Tex., May-Sept.; from Del., s. to Fla. and w. to Tex.; also W.I. and Mex. to C.A., S.A. and e. Asia.

41. HYDROCOTYLE L.

WATER-PENNYWORT

Plants low, glabrous or pubescent, herbaceous, perennial with slender creeping stems or rootstocks, rooting at the nodes; leaves peltate or nonpeltate, entire or parted to the base; inflorescence usually a simple umbel, sometimes proliferous or an interrupted spike, the axillary peduncles obsolete to much longer than the leaves; involucre inconspicuous, of numerous bracts; rays spreading to reflexed, sometimes obsolete; flowers white, greenish or yellow, the calyx teeth minute or obsolete, the stylopodium conspicuously conic to depressed; fruit ovoid to ellipsoid (broader than long), strongly flattened laterally, the dorsal surface rounded or acute, the dorsal ribs acute or obsolete, the slender lateral ribs conspicuous and acute or rarely obsolete; oil-bearing cells conspicuous to obsolete, strengthening cells usually surrounding the seed cavity, the seed face plane to concave.

A genus of about 100 species, chiefly of the tropics and the Southern Temperate Zone.

1. Leaves not peltate, the petioles attached in a sinus at one edge of the blade 5. *H. ranunculoides*.
1. Leaves peltate, the petioles attached to the middle of the blade (2)
- 2(1). Flowers and fruits in a simple (not proliferous) umbel 1. *H. umbellata*.
2. Flowers and fruits in a proliferous umbel or an interrupted spike (3)
- 3(2). Inflorescence profusely branched 4. *H. bonariensis*.
3. Inflorescence usually unbranched or only bifurcate (4)
- 4(3). Inflorescence often bifurcate; fruits sessile or subsessile 2. *H. verticillata* var. *verticillata*.
4. Inflorescence rarely bifurcate; fruits pedicellate 3. *H. verticillata* var. *triradiata*.

1. *Hydrocotyle umbellata* L. OMBLIGO DE VENUS. Plants glabrous; stems slender to somewhat thickened, floating or creeping; leaves orbicular-peltate, to 75 mm. in diameter, crenate or crenately lobed; petioles mostly slender, to 40.5 cm. long, usually much shorter;

peduncles usually exceeding the leaves, to 35 cm. long; umbels simple, many-flowered; rays to 2.5 mm. long, spreading and reflexed; stylopodium depressed; fruit orbicular to ellipsoid, 1-2 mm. long, 2-3 mm. broad, the dorsal surface acute, the dorsal and lateral ribs evident and obtuse; strengthening cells lacking. In wet places principally in the e. half of Tex., Apr.-Oct.; from N.S., s. to Fla., w. to Minn. and Tex.; also Ore., Calif., W.I. and from Mex., s. to S.A.

2. *Hydrocotyle verticillata* Thunb. var. *verticillata*. Plants glabrous; stems filiform, creeping; leaves orbicular-peltate, to 6 cm. in diameter, 7- to 14-veined, shallowly 8- to 13-lobed, the lobes crenate; petioles slender, to 26 cm. long, usually much shorter; inflorescence an axillary simple interrupted once- or twice-bifurcate (rarely tri- or quadrifurcate) spike, to 17 cm. long, with 2 to 7 few-flowered verticils, the interverticillar distance to 6 cm., the flowers sessile or subsessile; involucre of a few inconspicuous lanceolate bracts; fruit ellipsoid, 1-3 mm. long, 2-4 mm. broad, the dorsal surface acute, narrowly rounded to cuneate at the base, oblong in cross section, the acute dorsal and lateral ribs distinct, the commissural surface constricted; oil-bearing cells conspicuous; seed oblong-ovate in cross section. In wet places in the Timber Belt, Coastal and Blackland prairies and the Edwards Plateau, June-Aug.; from Mass., s. to Fla., w. to Mo., Tex., s. Ut., N.M., Ariz., Mex. and W.I.; also in H.I. and S. Afr.

3. *Hydrocotyle verticillata* var. *triradiata* (A. Rich.) Fern. Similar in habit to var. *verticillata*; leaves to 6 cm. in diameter, 8- to 14-nerved, shallowly 8- to 14-lobed; petioles slender, to 35 cm. long; inflorescence an axillary interrupted simple or rarely branched spike to 22 cm. long, with few 4- to 15-flowered verticils, the interverticillar distance to 4 cm., the flowers radiate, the rays to 1 cm. long. *H. Canbyi* Coult. & Rose, *H. australis* Coult. & Rose. In wet places chiefly in the Timber Belt, Coastal and Blackland prairies, Rio Grande Plains and Edwards Plateau, May-Aug.; from Mass., s. to Fla., w. to Nev. and Calif., also Mex., C.A., W.I. and S.A.

4. *Hydrocotyle bonariensis* Lam. **SOMBRELLLO**. Plants glabrous; stems slender, creeping; leaves orbicular to ovate-peltate, to 12 cm. in diameter, shallowly 12- to 19-lobed, the lobes crenate; petioles slender, to 37 cm. long; peduncles exceeding the leaves; umbels proliferous, many-flowered; rays to 2 cm. long, spreading and reflexed; involucre of lanceolate, acute bracts; flowers white to yellow; stylopodium depressed; fruit ellipsoid, 1-2 mm. long, 2-4 mm. broad, the dorsal surface acute, the acute dorsal and lateral ribs evident, the commissural surface constricted. In wet places in the Coastal and Blackland prairies, and on the Gulf side of the Rio Grande Plains, May-Nov.; from N.C., s. to S.A.; S. Afr.

5. *Hydrocotyle ranunculoides* L.f. Plants glabrous; stems slender to somewhat thickened, floating or creeping; leaves roundish-reniform with a sinus at the base, not peltate, to 8 cm. long and wide, 5- or 6-lobed about to the middle, the lobes crenate or lobulate; petioles mostly slender, to 34.5 cm. long; peduncles shorter than the leaves, axillary; umbels simple, 5- to 10-flowered; rays 1-3 mm. long, spreading and ascending; stylopodium depressed; fruit suborbicular, 1-3 mm. long, 2-3 mm. broad, the dorsal surface rounded, the ribs obsolete; strengthening cells absent. In wet places in the Timber Belt and Blackland Prairies, Apr.-July; from Pa. and Del., s. to Fla., w. to Ark. and Ariz.; also from Wash., s. along the coast to Pan., Cuba and S.A.

42. BOWLESIA R. & P.

A genus of 14 species, chiefly of South America.

1. *Bowlesia incana* R. & P. Plants annual from slender taproot, stellate-pubescent to glabrate, prostrate to suberect; stems slender, dichotomously branched, 1-5 dm. long or high; leaves opposite, with petioles to 7 cm. long, suborbicular in outline, to 3 cm. long and 45 mm. wide, palmately 5- to 7-lobed, the lobes entire to dentate; scarious stipules lacerate; peduncles to 2 cm. long, axillary, shorter than the leaves; umbels 2- to 6-flowered; involucre of a few subulate lacerate bracts; rays very short or obsolete; flowers white or purplish, the ciliate calyx teeth prominent, the styles very short, the stylopodium depressed-conic; carpophore entire; fruit sessile to subsessile, ellipsoid, 1-1.5 mm. long, 2-3 mm. broad; carpels depressed on the dorsal surface, the dorsal region inflated. *B. septentrionalis* Coult. & Rose. Adv. from S.A., in moist thickets and lawns, primarily, in s.e. half of Tex., Feb.-June; from Fla. to Calif. and Mex.; Eur., Asia and elsewhere.

FAM. 138. CORNACEAE DUM.

DOGWOOD FAMILY

Shrubs to large trees; leaves alternate or opposite, simple, entire or nearly so, without stipules; flowers regular, small, perfect or unisexual, 4- or 5-merous; calyx small or obsolete; petals (when present) 4 or 5; stamens 4 or as many as 12 in two series; filaments elongate; anthers introrse; pistil 1; styles 1 or 2; ovary inferior, 1- or 2-celled; fruit a drupe.

About 120 species in 14 genera, chiefly in the North Temperate Zone but also in the tropics of both hemispheres.

1. Large trees, mostly above 10 m. in height; leaves alternate; stamens 5 or more 1. *Nyssa*, p. 1170.
1. Shrubs or small trees, mostly less than 5 m. in height; leaves opposite; stamens 4 (2)
- 2(1). Flowers unisexual, apetalous, in catkinlike racemes; styles 2; leaves evergreen, with the opposing petioles basally connate 2. *Garrya*, p. 1171.
2. Flowers perfect, with petals, in open or congested cymes; style 1; leaves deciduous, the petioles free 3. *Cornus*, p. 1171.

1. NYSSA L.

TUPELO. SOUR-GUM

Trees with simple alternate deciduous leaves and greenish or greenish-white flowers borne at the summit of axillary peduncles; leaves entire or rarely slightly toothed, often crowded near tip of branchlets; flowers perfect or unisexual; *staminate flowers* numerous, the calyx small and 5-parted, the small fleshy petals soon deciduous or entirely lacking; stamens 5 to 12, inserted on the outer edge of a convex disk; *pistillate flowers* solitary or as many as 8, sessile in a bracted cluster, much larger than the staminate flowers; style simple, elongate; ovary 1-celled; fruit an ovoid to ellipsoid 1-seeded drupe.

A small genus of about 10 species in North America and Asia. Placed by some authors in the segregate family Nyssaceae.

1. Leaves usually much more than 1 dm. long, mucronate; staminate flowers sessile in a capitule; pistillate flowers solitary; fruits 20 mm. or more long; endocarp wing-ridged 1. *N. aquatica*.
1. Leaves usually less than 1 dm. long, not mucronate; staminate flowers pedicellate in an umbel or congested raceme; pistillate flowers 2 or more on a peduncle; fruits less than 15 mm. long; endocarp smooth or obtusely ridged (2)
- 2(1). Leaves obovate to broadly elliptic, typically about 2 times as long as broad, usually thin-textured, when young with a densely long-pilose petiole 2. *N. sylvatica* var. *sylvatica*.
2. Leaves mostly linear to oblanceolate, typically 3 times as long as broad, usually leathery, the petiole subglabrous or only sparsely short-pilose 2. *N. sylvatica* var. *biflora*.

1. *Nyssa aquatica* L. TUPELO, COTTON-GUM. Large tree to 30 m. or more tall, with the trunk somewhat swollen at base; leaves with petioles to 6 cm. long, ovate to broadly oblong-elliptic, cuneate or sometimes slightly cordate at base, rather abruptly acute to acuminate and mucronate at apex, to 3 dm. long and 1 dm. broad, pale and usually downy-pubescent on lower surface; fruit ellipsoid, bluish. *N. uniflora* Wang. In inundated swamps and along sluggish streams in e. Tex., Mar.-Apr.; from Va., s. Ind., s. Ill. and Mo., s. to Fla. and Tex.

2. *Nyssa sylvatica* Marsh. var. *sylvatica*. BLACK-GUM, SOUR-GUM, PEPPERIDGE. Rather large trees to 30 m. tall, with horizontally spreading branches; leaves with petioles to 2 cm. long, broadly rounded to abruptly acuminate at apex, lustrous on upper surface, smooth and glabrate or eventually glabrous on lower surface, to 14 cm. long and 7 cm. broad; fruiting peduncle usually more than 3 cm. long; fruits somewhat acid. Incl. var. *dilatata* Fern. and var. *caroliniana* (Poir.) Fern. In swamps, low woods and sandy open woodlands in e. Tex., Apr.-May; from Me., s. to Mo., Fla. and Tex.; also Mex.

Var. *biflora* (Walt.) Sarg. **BLACK-GUM**. Large trees to 35 m. tall, with the base of trunk swollen when submersed; leaves rounded to acute at apex, glabrous or nearly so, to 12 cm. long or more and rarely to 4 cm. broad; fruiting peduncle usually less than 3 cm. long; fruits bitterish. *N. biflora* Walt. In periodically inundated swamps, low wet woods and along streams in e. Tex., Mar.-Apr.; from Del. and Md., s. to Fla. and Tex.

2. GARRYA LINDL. SILK-TASSEL

Evergreen dioecious shrubs or small trees with 4-angled branchlets and opposite short-petioled leathery leaves; the opposing petioles basally connate; flowers unisexual, apetalous, in lax or dense pendulous spikes; *staminate flowers* pedicelled, in clusters of 3, with 4 stamens and a 4-parted calyx; *pistillate flowers* essentially sessile, solitary in the axils of the bracts, with the calyx 2-lobed or obsolete; ovary inferior, 1-celled; styles 2, persistent; fruit a dry or somewhat juicy drupe, the bitter pulp enveloping the 1 or 2 seeds, blackish or dark-purple.

About 18 species found only in North America. Segregated by some authors as a separate family, the Garryaceae.

1. Leaves typically elliptic to obovate, plane, with the margin smooth, not roughened nor muriculate; plants endemic to Edwards Plateau . . 1. *G. Lindheimeri*.
1. Leaves typically oblong-elliptic to ovate-elliptic, plane or undulate, with the margin roughened and more or less muriculate, especially above the middle; plants of the Trans-Pecos and Plains Country (2)
- 2(1). Leaves prominently undulate (especially when dry), when young the lower surface more or less covered with curled or crisped hairs 2. *G. ovata*.
2. Leaves plane, essentially glabrous or with the lower surface sparsely sericeous 3. *G. Wrightii*.

1. *Garrya Lindheimeri* Torr. Shrub or small tree 15-35 dm. tall; leaves oblong-elliptic to broadly elliptic or obovate, mostly broadly rounded and mucronate at apex, 4.5-8 cm. long, 2.5-5 cm. wide, plane, pubescent with curled or crinkly hairs on lower surface, with age becoming glabrate and lustrous on upper surface, the margins smooth and even; fruits blue, glaucous, 8-10 mm. in diameter. *G. ovata* var. *Lindheimeri* (Torr.) Coult. & Evans. On rocky slopes, ledges and bluffs, along streams and in ravines, limestone areas, endemic to Edwards Plateau, Mar.

2. *Garrya ovata* Benth. Shrub 15-25 dm. tall; leaves elliptic to ovate-elliptic, obtuse to subacute and apiculate at apex, 3-6 cm. long, 1.5-4 cm. wide, noticeably undulate or repand, when young densely tomentulose on both surfaces with loose curled or crinkly hairs, with age glabrate and lustrous on upper surface, the margins roughened and somewhat muriculate; fruits dark-blue, 4-8 mm. in diameter. *G. Goldmanii* Woot. & Standl. On steep slopes, in canyons and on ledges of mts. in the Trans-Pecos, reported from Plains Country, limestone and igneous areas, Mar.-Apr.; w. Tex., s. N.M. and n. Mex.

3. *Garrya Wrightii* Torr. Shrub or small tree 1-4 m. tall; leaves elliptic to broadly elliptic or oblong-elliptic, subobtusate to acute and mucronulate at apex, 3-5.5 cm. long, 1.5-3 cm. wide, when young sericeous, with age glabrous or nearly so, the margins roughened and somewhat muriculate; lowermost floral bracts foliaceous; fruits dark-blue, 4-7 mm. in diameter. Crevices of cliffs, among boulders and on open-wooded slopes in limestone and igneous-rock regions of the mts. of the Trans-Pecos, May-Aug.; from w. Tex. to s. Ariz. and n. Mex.

3. CORNUS L. DOGWOOD. CORNEL

Shrubs or small trees with opposite (in ours) deciduous leaves and small flowers in open cymes or close heads; flowers perfect; calyx minutely 4-toothed; petals 4, oblong-elliptic, obtuse, spreading; stamens 4, the filaments slender; style slender; stigma flat or capitate; fruit a small drupe, with a 2-celled and usually 2-seeded stone.

About 40 species in the North Temperate Zone.

1. Flowers in a congested cyme or head, subtended by a 4-bracted white or pinkish corollalike conspicuous involucre; fruits ellipsoid, red or rarely orange-yellowish 1. *C. florida*.
1. Flowers in open cymes; involucre none; fruit subglobose, blue or white (2)
- 2(1). Cymes elongate, laxly paniculate; pedicels usually bright-red; branches grayish; fruit white or creamy-white at maturity 2. *C. racemosa*.
2. Cymes broad, compact, flat or only slightly rounded across the top (3)
- 3(2). Leaves more or less scabrous on upper surface, pilose-woolly on lower surface; pith usually brown; fruits white at maturity 3. *C. Drummondii*.
3. Leaves glabrous or nearly so; pith white; fruits bluish at maturity 4. *C. foemina*.

1. *Cornus florida* L. FLOWERING DOGWOOD. Large shrubs or small trees to 12 m. tall, with a trunk to 5 dm. in diameter and a crown spreading to 11 m. or more across; branchlets usually greenish; leaves with petioles mostly less than 1 cm. long, ovate to ovate-elliptic or broadly elliptic, acute to acuminate at apex, tapering to a rounded base, to 12 cm. long and 8 cm. wide, dark-green on upper surface, pale and glabrous or silky-pubescent on lower surface; flowers yellowish-green to greenish-white, sessile, subtended by 4 white or pinkish showy petaloid bracts; bracts obovate, emarginate to somewhat pointed at apex, to 5 cm. long and 3 cm. wide, deciduous; fruits ellipsoid, 1-1.5 cm. long, dark-red to occasionally yellowish. *Cynoxylon floridum* (L.) Raf. In woodlands in e. and cen. Tex., Mar.-Apr.; in e. half of U.S., s.e. Can., s. to Fla. and Tex.

2. *Cornus racemosa* Lam. Shrub or small tree to 5 m. high, often forming thickets, the slender twigs reddish, soon becoming grayish, the pith usually pale-brown; leaves narrowly ovate or lanceolate to elliptic, mostly 4-8 cm. long, to about 4 cm. wide, abruptly long-acuminate, cuneate at base, papillose and somewhat whitened beneath, minutely appressed-strigillose on both sides; lateral veins 3 or 4 on each side; inflorescences often numerous, usually paniculiform, to 6 cm. long; pedicels and branchlets reddish; fruit at first lead-color, becoming white with maturity, 5-7 mm. high, the stone obliquely subglobose. *C. candidissima* Marsh., non Mill. In moist or wet soil on seepage slopes, in thickets and on stream banks in open woodlands in e. Tex., Apr.-June; from Me. to Man., s. to Fla. and Tex.

3. *Cornus Drummondii* C. A. Mey. ROUGH-LEAF DOGWOOD. Shrubs or small trees to 5 m. tall; branchlets gray or sometimes dark-brown or reddish, the pith brownish; leaves with petioles to 15 mm. long, ovate to elliptic-lanceolate, usually abruptly acuminate-attenuate at apex, to 10 cm. long and 6 cm. wide, more or less scabrous on upper surface, pilose-woolly on lower surface with the hairs mostly spreading; cymes (or corymbs) round-topped, pubescent, to about 75 mm. across; flowers white or creamy-white, somewhat malodorous; corolla cylindric in bud; petals 3.5-5.5 mm. long; fruits white, 5-6 mm. in diameter, the stone globose. *C. asperifolia* of auth. In damp woodlands and thickets, occasionally on dry hills, in e. half of Tex., Apr.-June; from e. Va., s. Ind. and s.e. Mo., s. to Fla. and Tex.

4. *Cornus foemina* Mill. ENGLISH DOGWOOD. Shrub or small tree to 4 m. tall; branchlets reddish or brown, smooth, the pith usually white; leaves with petioles 1 cm. or less long, broadly lanceolate to narrowly ovate-elliptic, tapering to a narrow elongate tip, to about 10 cm. long and 4 cm. wide, glabrous or nearly so, dark-green on upper surface, paler on lower surface; cymes round-topped, open; flowers creamy-white; corollas subcylindric in bud; anthers bluish; fruits bluish, about 5 mm. in diameter, the stone longer than broad and slightly furrowed. *C. stricta* Lam., *Svida stricta* (Lam.) Small. Swamps and low wet woodlands in e. Tex., May-June; from Ind. and Va., s. to Fla., La. and Tex.

FAM. 139. CLETHRACEAE KL.¹⁴¹

WHITE ALDER FAMILY

Shrubs with alternate serrate deciduous leaves, simple or stellate hairs and very fragrant flowers in crowded terminal simple or paniculate racemes; flowers regular, hypogynous,

¹⁴¹ Cf. Robert L. Wilbur in C. L. Lundell, *Flora of Texas* II: 18-20. 1969 for another treatment.

polypetalous, 5-merous; disk none; sepals separate, imbricate in bud; stamens 10, the filaments elongate; anthers sagittate, extrorse in bud, their sacs opening by pores at base and inverted at anthesis; ovary superior, 3-celled; style 3-cleft near summit; capsule globose, 3-valved, the valves 2-cleft at maturity, many-seeded, enclosed in the persistent calyx.

Only one genus.

1. CLETHRA L. SWEET PEPPER-BUSH. WHITE ALDER

Characters those of the family. Consisting of about 120 species that are found mainly in Asia and tropical America; also in temperate America and Madeira.

1. *Clethra alnifolia* L. Shrub to 3 m. tall; leaves 5-12 cm. long, obovate-elliptic to cuneate-obovate or occasionally elliptic-lanceolate, obtuse to shortly acuminate at apex, tapering to a petiole to 2 cm. long, sharply serrate above the middle, nearly entire below the middle, straight-veined; racemes erect, to 2 dm. long, densely short-pubescent; the deciduous bracts shorter than the flowers; flowers on short-pubescent pedicels 2-5 mm. long; calyx lobes triangular-ovate, acute, short-pubescent; petals white, oblong-obovate, about 8 mm. long; filaments glabrous; style slender; capsule pubescent, about 3 mm. in diameter, erect or ascending. In swamps, about lakes and in wet woods and thickets in s.e. Tex., July-Sept.; from Me. s. to Fla. and Tex.

In some regions this species is known as "poor man's soap"—the flowers when crushed in water form a lather.

FAM. 140. ERICACEAE JUSS.¹⁴² HEATH FAMILY

Shrubs, trees or rarely herbs or vines, evergreen or deciduous; leaves simple, alternate or rarely opposite or whorled, exstipulate, leathery to thin-herbaceous, entire or serrate; flowers perfect, regular or irregular, usually in racemes or panicles, rarely solitary; calyx of 4 to 7 distinct or partially united sepals, usually persistent; corolla of 4 to 7 distinct or united petals, commonly funnellform, campanulate or urceolate; stamens hypogynous, twice as many as the corolla lobes; anthers bilocular, often appendaged, dehiscing by "apical" slits, clefts or pores; style single, the stigma minute and discoid; fruit a loculicidal or septicidal capsule, drupe or berry.

Perhaps 2,000 species in about 75 genera nearly world-wide in distribution. A great many ornamental species occur in this family primary of which are the rhododendrons.

- 1. Plants parasitic or saprophytic herbs, without green coloring matter; leaves reduced to scales (2)
- 1. Plants autophytic and green, woody; leaves with well-developed blades (3)
- 2(1). Petals distinct; anthers without horns; plants glabrous or merely pubescent7. *Monotropa*, p. 1180.
- 2. Petals somewhat united; anthers horned; plants densely glandular-pubescent8. *Pterospora*, p. 1180.
- 3(1). Leaves coriaceous, evergreen; fruit a berry or drupe produced from a superior ovary, not juicy; found only in or west or north of the Edwards Plateau in Texas (4)
- 3. Leaves thin or sometimes coriaceous, deciduous or evergreen; fruit either a capsule from a superior ovary or a juicy berry produced from an inferior ovary; confined to the eastern third of Texas (5)
- 4(3). Small trees; cells of the ovary several-ovuled; fruit berrylike, only slightly fleshy, the surface granular-papillose1. *Arbutus*, p. 1174.
- 4. Shrubs; cells of the ovary 1-ovuled; fruit drupelike, dryish, the surface not granular2. *Arctostaphylos*, p. 1174.

¹⁴² Ref.: Carroll E. Wood, Jr. in Jour. Arnold Arb. 42:10-80. 1961.

- 5(3). Ovary inferior; fruit a juicy berry crowned by the persistent calyx teeth3. *Vaccinium*, p. 1175.
5. Ovary superior; fruit a dry capsule (6)
- 6(5). Corolla funnellform, elongate, the tube more or less glandular-stipitate; capsule ellipsoid-conic, septicidal4. *Rhododendron*, p. 1177.
6. Corolla urceolate, ovoid or cylindric, short, nonglandular; capsule subglobose to ovoid, loculicidal (7)
- 7(6). Inflorescence clearly elongate, racemose; sepals imbricate (at least in bud); capsule ovoid, truncate, the margins not differentiated5. *Leucothoë*, p. 1179.
7. Inflorescence of corymbose clusters in axils of leaves or bracts of the same or preceding season; sepals valvate or separated even in bud; capsule subglobose-compressed, the carpel midrib not differentiated ...6. *Lyonia*, p. 1179.

I. ARBUTUS L.

About 20 species in Asia, the Mediterranean region and the New World.

1. *Arbutus xalapensis* H.B.K. TEXAS MADRONE, NAKED INDIAN, LADY'S LEG. Small evergreen tree or rarely shrub, usually to 10 m. high or sometimes higher, with a trunk to 3 dm. in diameter; bark thin, pinkish to red-brown, peeling off in large papery sheets, the crooked stout spreading branches forming a distinct crown; leaves alternate, petiolate, ovate to oval or oblong-elliptic, to 1 dm. long and 45 mm. wide, rounded to acute at apex, rounded to subtruncate at base, coriaceous, entire or sometimes serrate, usually tomentose below when young, glabrate with age; flowers perfect, in tomentose panicles; floral bracts scaly, ovate, tomentose, concave, 3-4 mm. long; calyx lobes 5, scarious, pinkish-white, tardily deciduous; corolla ovoid-urceolate, 5-toothed, white, often pink-tinged, about 7 mm. long; stamens included, twice as many as the corolla lobes; filaments dilated at base; anthers compressed, bearing a pair of slender reflexed awns on back and each cell opening by a terminal pore; ovary 5-celled, pubescent; fruit dark-red to yellowish-red, 8-10 mm. in diameter, waxy-granular, edible. Incl. var. *texana* (Buckl.) Gray, *A. texana* Buckl. On wooded rocky hills and mt. slopes, in canyons and rarely on open plains in the Edwards Plateau, Trans-Pecos and South Plains, n. to Hockley Co., Feb.-Apr.; from Tex. and s.e. N.M., s. through Mex. to Guat.

2. ARCTOSTAPHYLOS ADANS.

About 40 species with all but one confined to the New World.

1. *Arctostaphylos pungens* H.B.K. MEXICAN MANZANITA. Shrub erect or ascending, to about 3 m. high, branching from the base to form thickets, with smooth red-brown exfoliating bark, the branchlets more or less cinereous with a fine tomentum; leaves alternate, with petioles to 1 cm. long, ovate to oblong-elliptic or obovate to oblanceolate, obtuse to acute and pungent at apex, narrowed and subcuneate at base, entire, coriaceous, persistent, to 3 cm. long and 15 mm. wide, cinereous-tomentose and somewhat bluish-green when young, becoming glabrate and dull-green or somewhat shining in age; racemes short, spikelike, simple or with 1 or 2 short branches; bracts triangular, about 3 mm. long, tomentose throughout; pedicels 5-7 mm. long, subtomentose to glabrous; flowers small, nodding; calyx 5-lobed, persistent; corolla cylindric-urceolate, white or pinkish, about 7 mm. long, with 5 short rounded recurved lobes; stamens 10, included; filaments dilated and usually hairy; anthers each with 2 dorsal awns, opening by terminal pores; ovary glabrous; fruit depressed-globose, glabrous, drupaceous, smooth, 5-8 mm. broad, chestnut-brown, edible; nutlets 4 to 10, separable or more or less coalescent, dorsally carinate and prominently roughened. On mt. slopes in the Trans-Pecos, rare, Feb.-Apr.; from w. Tex. to Ut. and Calif., s. in Mex. to Oax.

3. VACCINIUM L.¹⁴³

BLUEBERRY

Shrubs or small trees; leaves alternate, entire to serrate; flowers usually solitary, in clusters or racemes; corolla variously shaped, the limb 4- or 5-cleft; stamens 8 or 10; anthers awned on back or awnless, the cells opening by a terminal pore; berry 4- or 5-celled, many-seeded, sometimes 8- or 10-celled by false partitions extending from the back of each cell to the placenta, edible in most species.

A large genus of polymorphic species that are represented throughout the world. The edible fruits of several species provide the "blueberry" of the market place.

1. Flowers on specialized lateral branches, subtended by foliaceous bracts (2)
1. Flowers not on specialized branches, usually at the first nodes of a normal leafy branch (4)
- 2(1). Usually small trees or large shrubs; flowers and fruits articulated with pedicels; corolla enclosing the parts in bud; stamens enclosed in the usually broadly campanulate corolla at anthesis; leaves coriaceous, usually with some marginal teeth, shining or sometimes somewhat glaucous, essentially evergreen 1. *V. arboreum*.
2. Usually small shrubs, rarely arborescent; pedicels not articulated; corolla not enclosing the parts in bud; stamens exerted from the funnel-form corolla at anthesis; leaves thin, entire, dull-green or glaucous, deciduous (3)
- 3(2). Bracts of inflorescence conspicuously smaller than the foliage leaves, rarely more than 1 cm. wide; mature leaves rarely less than 5 cm. long 2. *V. stamineum*.
3. Bracts of inflorescence one half to nearly as large as the foliage leaves, 1-2 cm. wide; mature leaves to 5 cm. long 3. *V. caesium*.
- 4(1). Leaves coriaceous, evergreen, to 15 mm. long 4. *V. Darrowii*.
4. Leaves thin or thick-herbaceous, deciduous, 20 mm. or more long (5)
- 5(4). Lower surface of leaves bearing small glandular hairs (6)
5. Lower surface of leaves nonglandular (7)
- 6(5). Plants mostly less than 10 dm. high; leaves 3-4.5 (rarely 5) cm. long; corolla 6-9 mm. long 5. *V. virgatum*.
6. Plants 15 dm. or more high; leaves 4-5 (rarely 6.5) cm. long; corolla 9-12 mm. long 6. *V. amoenum*.
- 7(5). Leaves serrate, rarely more than 3 cm. long 7. *V. Elliottii*.
7. Leaves entire, rarely less than 5 cm. long 8. *V. arkansanum*.

1. *Vaccinium arboreum* Marsh. FARKLEBERRY, SPARKLEBERRY. Coarse shrub or small tree to 8 m. high, with a trunk to 3 dm. in diameter; leaves obovate to oblong-elliptic, mostly cuneate at base, rounded to obtuse and apiculate at apex, subentire or with some teeth (especially on lower margins), darker green and lustrous above, thick and leathery, to about 7 cm. long and 35 mm. wide, essentially evergreen in our area; flowers about 5 mm. long, spicy-scented, in loose leafy-bracted racemes, the bracts much smaller than and sometimes of different shape from the foliage leaves; pedicels jointed; corolla white, open-campanulate, the minute toothlike lobes recurved-reflexed; anthers included, their awns more than half the length of the tubular tips; style exerted; berry black or reddish-black, mostly hard and dry but sometimes somewhat moist, with hard stonelike seeds. *Batodendron arboreum* (Marsh.) Nutt. In sandy soils in pinelands, open mixed forests, thickets, clearings, fields and coastal scrub-forests, rather frequent along wooded streams, in e. and s.-cen. Tex., Mar.-May; from Fla. to Tex., n. to Va., s. Ind., s. Ill., s. Mo. and Okla.

Those plants that are more glaucous than usual have been segregated as var. *glaucescens* (Greene) Sarg.

¹⁴³ Adapted partly from W. H. Camp in Brittonia 5:203-275. 1945.

2. *Vaccinium stamineum* L. DEERBERRY, SQUAW-HUCKLEBERRY. Diffusely branched shrub to 3 m. high, commonly stoloniferous, the young branchlets and leaves more or less pubescent to essentially glabrous; leaves subsessile or with a petiole to 3 mm. long, ovate or oblong-elliptic to elliptic-lanceolate or elliptic-oblong, subcordate to rounded or cuneate at base, obtuse to acute and apiculate at apex, to 9 cm. long and 4 cm. wide, pale, often glaucous or whitened beneath; flowers 6-10 mm. long, in loose bracted racemes, pendulous on filiform pedicels about 1 cm. long; floral bracts similar to but usually much smaller than the foliage leaves, obtuse to acute, usually much less than 1 cm. wide; calyx glabrous or the lobes marginally ciliate; corolla white to greenish-white or purplish, open-campanulate, with 5 spreading lobes; anthers much-exserted, their awns much shorter than the tubular tips; berry juicy, tough-skinned, greenish to amber-color, sometimes purple or blue, with or without bloom, about 1 cm. in diameter, dropping promptly; seeds soft. *Polycodium stamineum* (L.) Greene. In sandy or clayey soils in pinelands, mixed forests, savannahs and bottomlands in s.e. Tex., rarely on wooded bluffs in n.e. Tex. (Bowie Co.), Mar.-May; from Tex. to Fla., n. to Mass., N.Y., s. Ont., O., Ind. and Mo.

This is a highly variable species and, east of Texas, a number of segregates have been proposed based on the presence or lack of pubescence and glaucousness of the leaves, stems, hypanthium and calyx. Most of these unstable variants can probably be found in our flora but they are scarcely worth recognizing.

3. *Vaccinium caesium* Greene. Small shrubs mostly less than 5 dm. high, pubescent to glabrate; leaves green or somewhat whitened beneath, typically oblong-elliptic, rounded to subcordate at base, usually bluntly obtuse-apiculate at apex, to 5 cm. long; bracts of inflorescence similar in shape to foliage leaves and one half to nearly as long as them, 1-2 cm. wide, noticeably exceeding the pedicels. In savannahs and open pine-hardwood forests in e. Tex., rare, Mar.-Apr.; from Fla. to Tex., n. to W.Va. and Pa.

This dubious species is distinguished from *V. stamineum* solely in having small, bluntly rounded foliage leaves, and bracts of the racemes 1-2 cm. wide and one half to nearly as large as the foliage leaves.

4. *Vaccinium Darrowii* Camp. Plants usually in extensive colonies, the stems twiggy above, rarely more than 4 dm. high; leaves coriaceous, evergreen, often markedly glaucous (especially when young), the lower surface nonglandular and usually glabrous or at most obscurely puberulent along the midvein, narrowly elliptic to spatulate, to 15 mm. long and 7 mm. wide, the margin entire or serrate (through introgression with *V. Elliottii*); corolla urceolate, 5-6 mm. long, pink or red; fruit blue, 4-6 mm. in diameter, of only fair flavor. Usually in dry sandy soil along open banks of creeks in s.e. Tex., Mar.; from Tex. to Fla.

5. *Vaccinium virgatum* Ait. Shrubs in rather extensive colonies, rarely more than 1 m. high; leaves deciduous, green, the lower surface conspicuously glandular, pubescent along the midrib or sometimes glabrous, spatulate to oblanceolate or narrowly elliptic, narrowly cuneate at base, acute to acuminate at apex, usually 3-4.5 (sometimes 5) cm. long and 1-1.5 (sometimes 2) cm. wide, the margin sharply serrate; corolla cylindrical-urceolate, 6-9 mm. long, pink-tinged, often conspicuously so; fruit usually shiny-black, 6-10 mm. in diameter, generally of poor flavor and texture. Mostly along streams in open forests, in boggy areas and flatwoods in e. Tex., Mar.-Apr.; from n. Fla., Ga. and Ala., w. to Tex. and Ark.

This species and *V. amoenum* are separated entirely upon size-differences of certain organs as given in the key. Although such a basis for separating species is usually eschewed, this particular characteristic for these two entities is remarkably constant.

6. *Vaccinium amoenum* Ait. Plants suckering to form dense clumps that are occasionally a meter or more in diameter at the base, sometimes crown-forming, 15-25 dm. high; leaves deciduous, dark-green or rarely slightly glaucous, the lower surface bearing conspicuous glands, pubescent along the veins or rarely glabrescent, obovate to oblanceolate or elliptic, cuneate at base, acuminate at apex, 4-5 (rarely to 6.5) cm. long and 15-25 (rarely to 30) mm. wide, the margin sharply serrate; corolla narrowly to broadly cylindrical-urceolate, 9-12 mm. long, often deep-pink; fruit black or dark-blue, 8-10 mm. in diameter, usually thick-skinned and of unpleasant flavor. Usually along streams in woodlands and on edge of woods and savannahs in e. Tex., Mar.-May; from S.C. to n. Fla., w. to Tex. and Ark.

7. *Vaccinium Elliottii* Chapm. ELLIOTT'S BLUEBERRY. Plants crown-forming or sometimes in much-restricted colonies, 2-4 m. high; leaves deciduous, usually thin-textured, green and shining, the lower surface nonglandular, glabrous to puberulent or even pubescent, usually broadly elliptic, to 3 cm. long and 15 mm. wide, the margins serrate or rarely subentire; corolla narrowly urceolate, 6-7 mm. long, usually some shade of pink; fruit usually dark, sometimes black and shining but often dull and occasionally glaucous, 5-8 mm. in diameter or larger in some forms, the flavor fair to poor. In open flatwoods and ravines, rarely in swampy areas and occasionally in cleared river bottoms that are subject to periodic flooding, in e. Tex., Feb.-Apr.; from s.e. Va., s. to Fla., w. to Tex. and Ark.

8. *Vaccinium arkansanum* Ashe. Large shrub, often with several stems, crown-forming or (if disturbed) suckering from a rather small base, 2-4 m. high; leaves deep-green, the lower surface rather pale and nonglandular, pubescent, broadly elliptic, rounded to cuneate at base, acute and apiculate at apex, to 8 cm. long and 4 cm. wide, the margin entire; corolla cylindric-urceolate, 6-8 mm. long, greenish-white, often with pink or red stripes or the whole surface suffused with pink; fruit dull-black or with a bloom, 7-10 mm. in diameter, of fine flavor. *V. atrococcum* and *V. corymbosum* of Texas reports. Sandy lake or stream margins or in swamps, occasionally in bogs or open flatwoods, in e. and s.e. Tex., Feb.-Apr.; from n. Fla., w. to Tex. and Ark.

This species has excellent possibilities of being improved and commercially grown for its tasty fruit on sour evergreen-shrub bog soils in southeast Texas. Where found, it produces abundant deep blue fruits with a fine blueberry flavor.

4. RHODODENDRON L.

RHODODENDRON. AZALEA

Shrubs or small trees, evergreen or deciduous; buds with several to many imbricate scales; leaves alternate, entire or rarely serrulate; flowers pedicellate, usually in umbellate clusters or corymbs; calyx small, 5-parted, persistent; corolla variously colored from white to purple or red, sometimes yellow, funnellform to tubular or rotate to campanulate, usually with a 5-lobed limb, deciduous; stamens mostly twice as many as the corolla lobes and greatly exceeding them, usually declined; anther cells opening by a small apical pore; style elongated and mostly surpassing the stamens, the stigma capitate; capsule septicidal, usually ellipsoid-conic, the seeds numerous.

About 600 species in temperate and cold regions of the Northern Hemisphere.

1. Outer surface of corolla lobes with stipitate glands extending up to or near the apex; flowers appearing (or expanding) after the leaves have unfolded; pedicels, calyx and capsules copiously stipitate-glandular; filaments usually only slightly exceeding the corolla (2)
1. Outer surface of corolla lobes without stipitate glands to near the apex, glabrous or at most puberulent or pubescent; flowers appearing before or with the leaves as they unfold; filaments usually conspicuously longer than the corolla (3)
- 2(1). Shrubs 4-10 dm. high, rhizomatous to form colonies 1. *R. Coryi*.
2. Shrubs rarely less than 10 dm. high, not noticeably rhizomatous or colonial 2. *R. oblongifolium*.
- 3(1). Pedicels, young twigs, petioles, calyx and capsules all canescent-strigose, rarely with a few short scattered inconspicuous glands 3. *R. canescens*.
3. Pedicels, young twigs, petioles, calyx and (to a lesser extent) the capsules all copiously and conspicuously glandular-stipitate 4. *R. prinophyllum*.

1. *Rhododendron Coryi* Shinnery. Shrub 4-10 dm. high, with a woody rhizome, the branches more or less strigose; leaves oblong-obovate to obovate-elliptic or oblanceolate, to 45 mm. long and 2 cm. wide, mostly marginally strigose; flowers produced after the leaves have unfolded; pedicels pubescent and glandular-stipitate; sepals much-abbreviated, pubescent and glandular-stipitate; corolla probably white, about 4 cm. long, the lobes dorsally glandular-stipitate up to or near the apex. In bogs and low woodlands along streams in s.e. Tex., Mar.-May; apparently endemic.

In Texas, this species replaces the similarly rhizomatous *R. atlanticum* (Ashe) Rehd. of eastern United States. It differs markedly, however, from that species. The pedicels, calyx and corolla of *R. Coryi* are not only adorned with stipitate glands but are also more or less densely pilose while those of *R. atlanticum* are essentially glabrous and only glandular-stipitate. The style of *R. Coryi* also is only puberulent or minutely pubescent near its base whereas the style of *R. atlanticum* is conspicuously long-pubescent in most or all of its lower half.

As in *R. oblongifolium*, the flowers in this species develop after the leaves have unfolded, whereas the flowers of *R. atlanticum* appear before or with the young leaves. There is little besides its rhizomatous habit and small stature to separate *R. Coryi* from *R. oblongifolium*. A more realistic treatment might be to consider it as only varietally different from *R. oblongifolium*.

2. *Rhododendron oblongifolium* (Small) Millais. Shrub to 25 dm. high; branchlets finely villous to glabrous and more or less reddish-strigose; buds grayish-pubescent; leaves short-petioled, obovate to elliptic or oblanceolate, to 1 dm. long, cuneate or only slightly rounded at base, rounded to acute and mucronate at apex, pubescent beneath to nearly glabrous and sometimes glaucescent; pedicels to 15 mm. long, hirsute to subglabrous and glandular-stipitate; flowers white, produced after the leaves are developed; sepals ovate to lanceolate, 1-3 mm. long, glandular; corolla tube usually stoutish, 2-3 cm. long, rather abruptly dilated at the apex, villous and copiously glandular-stipitate on the outside; corolla lobes dorsally glandular-stipitate up to or near the apex; styles white or pink; capsule ellipsoid-conic, 1.5-2 cm. long, blackish and sometimes shiny, profusely adorned with large stipitate glands. *Azalea oblongifolia* Small. In sandy or light soils in boggy or seepage areas, along wooded streams and ravines, and in open low pine and pine-hardwood forests in e. Tex. and La., Apr.-July or even as late as Sept.

In our region this species takes the place of the more eastern *R. viscosum* (L.) Torr. (*Azalea viscosa* L.) which it closely resembles and under which name our plant has been placed in the past. It is our most widespread and frequent rhododendron, and it also begins flowering a little later than the other species found in Texas. The flowers are manifestly viscid or glutinous to the touch.

3. *Rhododendron canescens* (Michx.) Sweet. HOARY AZALEA. Shrub to about 3 m. high, sparingly branched; branchlets canescent-pilose and more or less strigose and sometimes with scattered small glands; leaves mostly oblanceolate to narrowly obovate or oblong, subglabrous to grayish-pubescent or tomentose beneath, to 11 cm. long, cuneate at base, rounded to subacute and mucronate at apex; flowers produced before or with the leaves, slightly fragrant; pedicels canescent-strigose, rarely sparsely glandular; calyx lobes glandless, canescent; corolla tube slender, 15-23 mm. long, usually pink, abruptly expanded at the apex, about twice as long as the whitish glandless lobes; filaments mostly about 3 times the length of the corolla tube; style 4-6 cm. long; capsule dark-brown, ellipsoid, about 15 mm. long, villous-setose, nonglandular. *Azalea canescens* Michx. In sandy or light soils in and on the edge of bogs, in seepage areas, along wooded streams and in pine-hardwood flats in e. Tex., Mar.-May; from Fla. to Tex., n. to Del., Md. and O.

This species includes those plants from Texas that have previously been placed in *R. nudiflorum* (L.) Torr. (*Azalea nudiflora* L.). The name, var. *subglabrum* Rehd., has been assigned to those plants with glabrous or glabrescent leaves.

4. *Rhododendron prinophyllum* (Small) Millais. HONEYSUCKLE, EARLY-AZALEA. Shrub to about 3 m. high; branchlets finely pubescent and more or less strigose and glandular-stipitate; buds grayish-pubescent; leaves usually narrowly oblanceolate to elliptic, sometimes obovate, more or less dull-bluish-green in color, to 9 cm. long, obtuse to acute or short-acuminate, grayish-pubescent or short-pilose beneath, more or less pilose above; flowers produced with the leaves, very fragrant; pedicels with stipitate glands among the villosity; calyx lobes ovate, rarely 1 mm. long, glandular-ciliate; corolla glandular-stipitate and villous, bright-pink varying to whitish or with the tube rose-color; corolla tube 1.5-2 cm. long, gradually dilated upward, more or less glandular-stipitate on outside, pubescent inside, about equaling the glandless lobes; filaments mostly about twice the length of the corolla tube; style 4-5 cm. long, commonly purplish above base; capsule dark-brown, oblong-ellipsoid, 1.5-2 cm. long, slightly puberulous and somewhat glandular. In sandy or light soils usually in moist or wet situations in swamps, along wooded streams and in

bog areas in s.e. Tex., late Feb.-May; from Me. to Que., s. and s.w. to Tenn., Mo. and Tex.

5. LEUCOTHOE D. DON

FETTER-BUSH. LEUCOTHÖE

About 50 species mostly in the New World with several in eastern Asia.

1. *Leucothoe racemosa* (L.) Gray. Deciduous shrub to 4 m. high, with ascending branches; leaves alternate, short-petioled, oblong to oblanceolate or obovate, acute to short-acuminate, finely serrulate, to 8 cm. long, somewhat pubescent when young; racemes mostly solitary, somewhat secund, ascending or divergent, mostly terminating leafless branches of the previous year, to 7 cm. long; pedicels 2-3 mm. long; flowers white, 5-merous, scaly-bracted; sepals ovate-lanceolate, ciliate, about 3 mm. long, persistent, imbricated in bud; corolla 7-9 mm. long, tubular, constricted at throat, the short lobes spreading; stamens 10; anther-cells each 2-awned; capsules depressed-globose, not lobed, 2.5-3 mm. long, 3-4 mm. thick, the style long-persistent, the sutures not thickened; seeds angled and wingless. *L. elongata* Small. Moist thickets, swamp forests and sunny lake shores in s.e. Tex., spring-fall; from Tex. to Fla., n. to Mass., s.e. N.Y. and e. Pa.

6. LYONIA NUTT.

Shrubs or rarely arborescent, deciduous or evergreen; leaves alternate, herbaceous to coriaceous, entire or serrulate; flowers white to rose-color, 5-merous, long-pedicellate, in fascicles, racemes or panicles; calyx lobes valvate; corolla cylindric-ovoid to globose-urceolate, with short lobes; stamens 10; filaments basally dilated, hairy and often toothed or appendaged; anthers ovate to oblong, awnless, opening by 2 terminal pores; capsule globose to ovoid, scarcely 5-angled, the dorsal sutures with a thickened ridge that usually divides at dehiscence of the capsule.

About 30 species in Asia and the New World.

1. Leaves serrulate; inflorescence paniculate; sepals triangular, 1-1.5 mm. long; corolla globose- to ovoid-urceolate, white, about 3 mm. long . . . 1. *L. ligustrina*.
1. Leaves entire; inflorescences umbellate-racemose; sepals oblong, 3-10 mm. long; corolla nodding, cylindric-ovoid, white to pink, 8-13 mm. long 2. *L. mariana*.

1. *Lyonia ligustrina* (L.) DC. HE-HUCKLEBERRY, MALEBERRY. Shrub to 4 m. high, sometimes arborescent, deciduous, the bark scaly; leaves short-petiolate, thin, elliptic or elliptic-lanceolate to obovate or oblanceolate, acute to abruptly acuminate, to 95 mm. long and 45 mm. wide, serrulate to rarely subentire; racemes borne in panicles terminating the branches or from the upper axils, the bracts (in ours) foliaceous; sepals 1-1.5 mm. long, broadly triangular; corolla whitish, globose- to ovoid-urceolate, to 3 mm. long; filaments flat, not appendaged; capsule globose to subglobose, to 3 mm. long, about 4 mm. thick. Incl. var. *capreaefolia* (Wats.) DC. In bog and seepage areas, and along wooded streams in e. Tex., Apr.-June; from Fla. to Tex., n. to N.E., N.Y., W.Va., Ky., Ark. and Okla.

2. *Lyonia mariana* (L.) D.Don. STAGGER BUSH. Slender upright shrub, usually with stems naked below and with strongly ascending branches above, usually more or less pilose throughout, to about 2 m. high, usually less than 1 m. high; leaves shortly petiolate, borne on new shoots, deciduous, elliptic-oblong to elliptic-lanceolate or narrowly obovate, obtuse to acute, to 11 cm. long and 5 cm. wide, entire; inflorescences umbellate-racemose, fascicled along leafless old branches; pedicels 1-2 cm. long, bracteolate at the very base; flowers nodding; sepals narrowly oblong, to 1 cm. long, tardily deciduous; corolla cylindric to cylindric-ovoid, 8-13 mm. long, white or pinkish; filaments usually bidentate near apex; capsule ovoid-pyramidal, truncate at the contracted apex, about 7 mm. long, surrounded by the finally appressed sepals. Peaty or sandy pinelands and edge of evergreen shrub bogs, usually in moist soils, in e. and s.-cen. Tex., Mar.-June; from Fla. to Tex., n. to s. N.E., s.e. N.Y., e. Pa., w. Tenn., s. Mo. and Ark.

The foliage is considered to be poisonous to young grazing animals.

7. MONOTROPA L.

Low fleshy herbs, apparently devoid of chlorophyll, variously colored tawny, reddish or white, turning black in drying, parasitic or growing on decomposing vegetable matter; stems clustered, erect, arising from a mass of matted fibrous brittle roots; leaves reduced to bracts along the stems; flowers one to several, at first nodding but erect in fruit; calyx of 2 to 5 bractlike segments, deciduous; corolla urceolate or broadly tubular, composed of erect spatulate or cuneate scalelike petals that are gibbous or saccate at the base and tardily deciduous; stamens 8 or 10; filaments subulate, pubescent; anthers becoming 1-celled, opening by 2 clefts across the top; style columnar; stigma discoid, 4- or 5-rayed; capsule ovoid, 8- to 10-grooved, the 4 or 5 cells loculicidal.

A few widely distributed species in the Northern Hemisphere.

1. Plants glabrous, 1-flowered, inodorous; style much-abbreviated and broad, glabrous, shorter than the ovary 1. *M. uniflora*.
1. Plants more or less pubescent, with several flowers in a scaly raceme, mostly fragrantly aromatic; style commonly longer than the ovary, pubescent (2)
- 2(1). Plant mostly yellowish; bracteal leaves typically ovate-oblong and 1 cm. or less long; distribution northeast Texas 2. *M. Hypopithys*.
2. Plant mostly reddish; bracteal leaves typically suborbicular-ovate and more than 1 cm. long; distribution Trans-Pecos Texas 3. *M. latisquama*.

1. *Monotropa uniflora* L. INDIAN-PIPE. Plants to about 2 dm. high, smooth, at first waxy-white, finally tinged with rose-color, drying black, the stems solitary or several; leaves scalelike, 5-10 mm. long; flower solitary, nodding, to 15 mm. long; sepals 2 to 4, linear-oblong to oblong-spatulate, soon deciduous; petals 5 or 6, exceeding the sepals, oblong-spatulate; filaments pubescent; capsule ovoid-oblong, 1-1.5 cm. long. In humus of moist pine-hardwoods in e. Tex., Apr.-July; from Nfld. to Alas., s. to Mex.; also e. Asia.

2. *Monotropa Hypopithys* L. AMERICAN PINESAP. Plants to about 25 cm. high, yellowish, finally tinged with pink or crimson, darkened in drying, downy or finely pubescent throughout; leaves scalelike, ovate-oblong, 5-12 mm. long; flowers few and separated or rather numerous and crowded, to 15 mm. long; pedicels about as long as or shorter than the flowers; sepals as many as the petals, cuneate to narrowly oblanceolate, acute to acuminate; petals cuneate to cuneate-oblong, exceeding the sepals; filaments and style pubescent; stigma clavate, retrorsely bearded on the margin; capsules ovoid to globose, 4-5 mm. long. Moist woods in deep humus in n.e. Tex., Apr.-June; from Nfld. to Alas., s. to Mex.; also Euras.

3. *Monotropa latisquama* (Rydb.) Hult. Plants usually red or pink, the stem rather stout, more or less pubescent throughout, to about 3 dm. high; leaves thickish, broadly ovate to orbicular-ovate, the larger upper ones 1-1.5 cm. long, undulate or erose; bracts shorter than the flowers; flowers about 12 mm. long; sepals spatulate to narrowly cuneate, ciliate; petals cuneate to obovate, pubescent, ciliate; filaments 7-8 mm. long; capsules globose-ovoid, 6-7 mm. long. In rich soil under conifers in mt. canyons of the Trans-Pecos, Oct.-Nov.; from Alas., s. to w. Tex., N.M. and Mex.

8. PTEROSPORA Nutt.

A monotypic genus of temperate North America.

1. *Pterospora Andromeda* Nutt. PINEDROPS. Saprophytic herb with brownish or purplish herbage, the stems erect and simple, to 1 m. high, viscid-pubescent, arising from a thick ball-like mass of roots; leaves crowded below, scalelike, linear-lanceolate, 15-35 mm. long, mostly crowded at base of stem, the upper ones scattered and small; raceme erect, virgate, to 5 dm. long, many-flowered; flowers nodding on recurved pedicels; sepals 5, linear-lanceolate, 4-5 mm. long, glandular-pubescent, slightly united at base; corolla urceolate, 7-8 mm. long, white, the 5 short lobes rounded and recurved, marcescent; stamens 10, included, with slender filaments, the 2 dorsal appendages of the anthers about as long as the pollen sacs; ovary 5-celled, depressed-globose, the short style stout, the capitate-peltate stigma shallowly 5-lobed; capsule 8-12 mm. broad, strongly depressed,

5-lobed, loculicidal; seeds numerous, broadly winged at the apex. Growing in humus in coniferous forests in the Guadalupe Mts. of the Trans-Pecos, June-Sept.; from Tex., n.e. to Pa., w. to B.C. and Calif., also n. Mex.

The eastern Sorrell-tree or Sourwood, *Oxydendrum arboreum* (L.) DC. has been reported from Texas, but we have seen no material from the state. We believe the report to be erroneous and based on misidentified material. This is a small deciduous tree with long elliptic-lanceolate leaves and small white flowers in long one-sided racemes that are clustered in open panicles that terminate the branches of the season. On the living trees the inflorescences have a graceful "down-swept" appearance.

FAM. 141. PRIMULACEAE VENT.¹⁴⁴

PRIMROSE FAMILY

Annual or perennial herbs with simple or rarely dissected leaves and regular perfect usually 5-merous flowers; calyx free from or partially adherent to the ovary, merely toothed or divided nearly to base; corolla gamopetalous, shallowly lobed to deeply divided; stamens as many as the lobes of the corolla and inserted opposite to them on the tube or at base of lobes; ovary 1-celled, with a central free placenta rising from the base and bearing several to many seeds; style and stigma one, the stigma truncate to capitate; fruit a dehiscent capsule.

About 1,000 species in about 20 genera that are widely distributed in the Northern Hemisphere.

1. Aquatic plants with pectinately dissected leaves; flowers in whorls on the conspicuously inflated floating peduncles 1. *Hottonia*, p. 1181.
1. Terrestrial or marsh plants with entire or merely toothed leaves; flowers solitary, umbellate or racemose (2)
- 2(1). Ovary partially inferior, adnate to the calyx tube; inflorescence racemose, the pedicels bracteate or ebracteate 2. *Samolus*, p. 1182.
2. Ovary wholly free from the calyx (3)
- 3(2). Scapose; flowers in involucrate umbels (4)
3. Caulescent; flowers solitary in the leaf axils or in racemes (5)
- 4(3). Low rosulate annuals with pubescent leaves; corolla inconspicuous, the lobes erect or spreading at anthesis; calyx accrescent, the lobes green and not ridged, the tube white and prominently ridged; stamens distinct, included 3. *Androsace*, p. 1183.
4. Perennials with broad glabrous or glabrate leaves; corolla conspicuous, the lobes reflexed at anthesis; calyx herbaceous and not ridged, the lobes and tube similar in texture; filaments connate below, the anthers forming an exerted cone 4. *Dodecatheon*, p. 1183.
- 5(3). Capsule valvate; corolla yellow; perennials with opposite or whorled leaves; flowers 5- or 6-merous 5. *Lysimachia*, p. 1184.
5. Capsule circumscissile; corolla scarlet, salmon-color, blue or white; annuals with alternate or opposite leaves; flowers 4- or 5-merous (6)
- 6(5). Leaves opposite or whorled; corolla exceeding the calyx 6. *Anagallis*, p. 1185.
6. Leaves alternate; corolla shorter than calyx 7. *Centunculus*, p. 1185.

1. HOTTONIA L.

FEATHERFOIL. WATER-VIOLET

Two species, the Eurasian *H. palustris* L. and the present one in the United States.

1. *Hottonia inflata* Ell. AMERICAN FEATHERFOIL. Aquatic herb with the erect or ascending hollow leafless flower stems to 3 dm. long, the internodes inflated; submersed stems to

¹⁴⁴ Ref.: R. B. Channell and C. E. Wood, Jr. in Jour. Arnold Arb. 40:268-288. 1959.

5 dm. long; leaves oblong in outline, to about 7 cm. long, dissected into filiform divisions, clustered at base of flower stems and scattered along the rooting and floating vegetative stems; flowers white, pedicellate, subtended by sepeloid bracts, several in whorls at the nodes or joints to form an interrupted raceme; calyx and corolla subequal, 4-5 mm. long; calyx 5-parted, the divisions linear; corolla with a short tube, the limb 5-parted; stamens 5, included, the filaments short; capsule subglobose or obpyriform, many-seeded, the 5 valves cohering at base and summit; seeds anatropous. In lakes, pools and ditches in e. Tex., Apr.-June; from Fla. to Tex., n. to N.E., N.Y., O., Ind., s. Ill. and Mo.

This species has the potential nuisance value of the water hyacinth (*Eichhornia crassipes*).

2. SAMOLUS L.

WATER-PIMPERNEL. BROOKWEED

Perennial somewhat succulent caulescent herbs; leaves in basal rosettes and then usually alternate on stem, entire; flowers on wiry pedicels in simple or paniced bracted or naked racemes; calyx herbaceous, campanulate, 5-lobed, persistent; corolla perigynous, white or pink, the tube short, the 5 rounded lobes imbricated; stamens 5, included, adnate to the corolla tube, sometimes alternating with 5 narrow staminodia that are in the sinuses between the corolla lobes; anthers cordate, erect; ovary half-inferior, 1-celled, the stigma obtuse or capitate; ovules numerous, half-anatropous, in a subglobose placenta; capsule subglobose, 5-valved at the thickened apex; seeds numerous.

About 10 species that are widely distributed, especially in the Southern Hemisphere.

1. Racemes sessile or nearly so; corolla lobes longer than tube, with staminodia in the sinuses between the lobes 1. *S. parviflorus*.
1. Racemes long-peduncled; corolla lobes usually much shorter than tube, the staminodia wanting (2)
- 2(1). Peduncles and racemes glandular-pilose; corolla 4-6 mm. broad, the lobes typically cuneate-obovate; distribution inland Texas 2. *S. cuneatus*.
2. Peduncles and racemes glabrous; corolla 6-9 mm. broad, the lobes typically suborbicular; distribution coastal Texas 3. *S. ebracteatus*.

1. *Samolus parviflorus* Raf. Plant light-green, glabrous, to 6 dm. tall, the stems simple or diffusely branched; leaves obovate to spatulate or oblanceolate, sessile or narrowed into a winged petiole, rounded to obtuse at apex, to 15 cm. long and 4 cm. wide; racemes sessile or nearly so, the slender rachis straight or flexuous; pedicels filiform, spreading or ascending, to 2 cm. long; calyx lobes ovate to triangular-ovate, acute, about as long as or shorter than the tube; corolla white, 2-3 mm. broad; corolla lobes oblong, rounded or emarginate at apex and longer than the tube; staminodia 5; capsule 2-3 mm. in diameter. *S. floribundus* H.B.K. In wet soils and about various types of wet rocks, along streams, about lakes and seepage areas throughout Tex., Mar.-Sept.; from Fla. to Calif. and Mex., n. to e. Can., Mich., Ill. and B.C.; also trop. Am.

2. *Samolus cuneatus* Small. Plant deep-green, to 6 dm. tall, usually much smaller, the usually branched stems more or less tufted and ascending or reclining; leaves obovate to oblanceolate or broadly spatulate, the bases decurrent as broad wings, rounded and usually minutely mucronate at apex, to 15 cm. long and 6 cm. wide; racemes with stoutish straight peduncles longer than the stems, both more or less glandular-pilose; pedicels slender, spreading or ascending, to 3 cm. long; calyx lobes triangular, acute, somewhat roughened in appearance and often purple-tinged, longer than or about as long as the tube; corolla white, 4-6 mm. broad; corolla lobes broadly cuneate to cuneate-obovate, somewhat coarsely toothed at the rounded to subtruncate apex; capsules 3-4 mm. in diameter. *S. ebracteatus* subsp. *cuneatus* (Small) Knuth. On wet limestone and seepage areas or in moist soil along streams and rivers from cen. to Trans-Pecos Tex., s. to the Rio Grande Plains, Mar.-Oct.; also n. Mex.

3. *Samolus ebracteatus* H.B.K. Plant glabrous, bright-green or glaucous, to 55 cm. tall, the usually sparingly branched stems solitary or tufted and erect or ascending; leaves spatulate to obovate, sessile or with winged petioles, decurrent, rounded to obtuse and sometimes apiculate at apex, to 1 dm. long and 35 mm. wide, usually much smaller; racemes with stoutish erect straight peduncles that usually exceed the stems, to 2 dm.

long; pedicels ascending, to 5 cm. long, usually much shorter; calyx lobes triangular-ovate to triangular-lanceolate, acute, equal to or up to about twice as long as the tube; corolla pink or whitish, 6-9 mm. broad; corolla lobes suborbicular, rounded and often noticeably erose or retuse at apex, with a glandular tuft at base, shorter than the tube; stigma subentire to notched; capsules 3-4 mm. in diameter. In salt marshes and flats, in saline and brackish soil; and on dunes and in sandy soil on the coast of Tex., Apr.-Oct.; from Fla. to Tex. and Mex.; also W.I.

A glaucous plant that is more or less confined to dry sands along the coast is segregated as *S. alyssoides* Heller [*S. ebracteatus* subsp. *alyssoides* (Heller) Knuth]. It is described as having flowers with pedicels to 1 cm. long and a corolla 6-9 mm. broad. It apparently is closely related to *S. ebracteatus*.

3. ANDROSACE L. ROCK-JASMINE

Small annual herbs with clustered radical leaves and very small flowers in an umbel terminating a scape; calyx 5-cleft, the obconic tube short; corolla salverform or funnel-form, the somewhat inflated tube shorter than the calyx, constricted at the throat, the limb 5-parted; capsule longitudinally 5-valved, enclosed in the persistent calyx.

About 100 species in cooler parts of the North Temperate Zone.

- 1. Calyx lobes linear-elliptic to triangular-lanceolate, equal to or longer than the tube; involucre bracts broadly elliptic-obovate to oblanceolate 1. *A. occidentalis*.
- 1. Calyx lobes deltoid, much shorter than the tube; involucre bracts narrowly lanceolate to subulate 2. *A. septentrionalis* var. *glandulosa*.

1. *Androsace occidentalis* Pursh. Dwarf plants to 7 cm. tall, usually much smaller; rosette leaves typically elliptic-obovate, to 2 cm. long and 6 mm. wide, entire or somewhat coarsely dentate above middle, white-pubescent above with mostly simple hairs; scapes one to many, erect or recurved-ascending, more or less equal in length, scabrous with stellate hairs; involucre bracts elliptic-obovate to oblanceolate, to 6 mm. long; pedicels erect or ascending, mostly less than 25 mm. long, stellate-pubescent; calyx tube pale, campanulate, the bright-green pubescent lobes linear-elliptic to narrowly triangular-lanceolate. Dry soils in open country or in open rocky woods in cen. and w. Tex., Feb.-Apr.; from Ont. to B.C., s. to Tex., N.M. and Ariz.

2. *Androsace septentrionalis* L. var. *glandulosa* (Woot. & Standl.) St. John. Plant to 3 dm. tall, more or less puberulent with reddish glandular hairs; rosette leaves linear-spatulate to oblanceolate, to about 35 mm. long and 6 mm. wide above middle, often with stellate pubescence, entire or jagged-toothed; scapes usually several, erect, only the central one well-developed with the others much shorter or wanting; umbels compact; involucre bracts mostly linear-subulate, to 3 mm. long; pedicels strictly ascending or erect, to at least 55 mm. long, soon glabrate; calyx turbinate-campanulate, stramineous to green, with short deltoid lobes. *A. glandulosa* Woot. & Standl. In open rocky areas on mt. summits in the Trans-Pecos, June-July; in high mts. of s.w. U.S.

4. DODECATHEON L. SHOOTING-STAR. AMERICAN COWSLIP

About 50 species in North America and Asia.

1. *Dodecatheon Meadia* L. Perennial glabrous herb with fibrous roots and a cluster of basal leaves from which arise a simple naked scape to 55 cm. high that supports at the summit an involucre of small bracts that subtend an umbel of showy flowers; leaves narrowly elliptic-oblong to oblanceolate, blunt or rounded at apex, tapering from the reddish-tinged base into the petiole, usually with entire margins, to 2 dm. long and 4 cm. wide above middle; flowers few to many; pedicels slender, erect when young, recurving in anthesis, ascending in fruit; calyx lobes 5, lanceolate, usually about 5 mm. long in anthesis, slightly longer and persistent in fruit; corolla lilac to pale-pink, with a very short tube and thickened throat, the 5 oblong-elliptic lobes to 25 mm. long and 1 cm.

wide, strongly reflexed; tube of filaments 1-2 mm. long; anthers linear, about 8 mm. long, connivent to form a slender cone; capsule ovoid, dark-reddish-brown, to 18 mm. long, with firm ligneous walls, opening by 5 short terminal valves. On open slopes, base of bluffs, in cedar brakes and in open moist woods in e. third of Tex. w. rarely to Travis Co., Mar.-May; from D.C., w. to Wisc., s. to Ga. and Tex.

5. LYSIMACHIA L. LOOSESTRIFE

Leafy-stemmed perennials with entire opposite or whorled leaves and long-pedicelled yellow to orange-color and sometimes purple-dotted corollas; calyx 5- or 6-parted, imbricate or valvate in bud; corolla 5- or 6-parted, rotate, convolute in bud or with each division convolute about its stamen; stamens 5, the filaments distinct or nearly so on a ring at base of corolla or monadelphous at base, the anthers ovoid to slender; capsule subglobose to ovoid, few- to many-seeded, the style persistent on one valve.

About 200 species of wide distribution, especially eastern Asia and North America.

1. Stems of flowering branches arched-reclining or creeping, often rooting at nodes; divisions of corolla 3-5 mm. long 1. *L. radicans*.
1. Stems erect, slender, arising from slender cordlike rhizomes and stolons; divisions of corolla 7-13 mm. long (2)
- 2(1). Principal leaves ovate or ovate-lanceolate, with rounded or cordate base with a distinct petiole 2. *L. ciliata*.
2. Principal leaves linear to linear-lanceolate, gradually tapering at base 3. *L. lanceolata*.

1. *Lysimachia radicans* Hook. Stem slender, soon reclined, to 1 m. long, laxly and diffusely branched, the elongated branches often rooting at the nodes; leaves membranous, with a slender narrowly winged bristly-ciliate petiole to 3 cm. long; blade ovate-lanceolate to lanceolate, to 9 cm. long and 25 mm. wide, rounded at base, acuminate at apex; pedicels filiform, to 3 cm. long; flowers nodding, to 12 mm. wide; calyx segments ovate-lanceolate, acuminate, 3-5 mm. long; corolla segments obovate-cuneate, erose-dentate and cuspidate; capsule exceeding the calyx. *Steironema radicans* (Hook.) Gray. In swamp forests, along streams and in moist pinelands in s.e. Tex., May-July; from Miss. to Tex., n. to Mo., Tenn. and locally to e. Va.

2. *Lysimachia ciliata* L. Stem erect, simple or branched, 12 dm. high from a slender rhizome; leaves ovate to ovate-lanceolate, acuminate, broadly rounded to subcordate at the base, the blades to 15 cm. long with long ciliate-fringed petioles; flowers on thin axillary peduncles, mostly whorled, to 28 mm. wide; calyx segments firm, subulate-tipped, to 1 cm. long; corolla yellow, not spotted, its broad segments cuspidate and erose-dentate; capsule exceeding or shorter than the mature calyx. *Steironema pumilum* Greene. Swamps, marshes, low ground, thickets, rich woods and shores in n.e. Tex., June-Aug.; from s. Can. to Fla., to Tex, Ariz. and Colo.

3. *Lysimachia lanceolata* Walt. Stems slender and firm, from elongate slender cordlike rhizomes and stolons, to 7 dm. tall, simple or with ascending branches; basal leaves often rosulate and long-petiolate, elliptic to oblong-elliptic, usually persistent; middle and upper leaves linear or linear-lanceolate, to 13 cm. long and 15 mm. wide, attenuate to the usually short-petiolate bristly-ciliate base, acuminate at apex, paler beneath; pedicels filiform, to 4 cm. or more long at anthesis, from upper axils; flowers to 2 cm. wide; calyx segments firm, linear-lanceolate, acuminate, to 7 mm. long; corolla segments suborbicular to broadly obovate, erose, cuspidate; filaments equalling or longer than anthers; capsule shorter than the calyx. *Steironema lanceolatum* (Walt.) Gray. Dry or moist open woods, in thickets, sometimes in or about water of lakes, seepage and streams in e. Tex., May-July; from Fla. to Tex., n. to Pa., O., w. to Mich. and Wisc.

A plant segregated as *L. hybrida* Michx. [*L. lanceolata* subsp. *hybrida* (Michx.) Ray] has been reported from Texas. It is considered to be closely allied to *L. lanceolata* from which it differs in having a thicker, more robust stem with longer internodes, basal offshoots and nonpersistent essentially sessile basal leaves, no cordlike rhizomes, and a more open-paniculate inflorescence. The leaves are also green on both surfaces instead of being pale-green or somewhat glaucous beneath as in *L. lanceolata*.

6. ANAGALLIS L. PIMPERNEL

About 28 species that are cosmopolitan in distribution.

1. *Anagallis arvensis* L. SCARLET PIMPERNEL, HIERBA DEL PÁJARO. Low spreading or procumbent annual herb with opposite leaves and solitary flowers on axillary pedicels, forming loose prostrate mats, the diffuse 4-angled stems much-branched and to 3 dm. long; leaves sessile or somewhat clasping the stem, suborbicular to ovate or elliptic, to 2 cm. long and 1 cm. wide; pedicels slender, exceeding the leaves; flowers variable in size and color, from scarlet to salmon-color and sometimes almost white or blue [in f. *caerulea* (Schreb.) Baumg.] with the petals more or less without cilia; calyx lobes lanceolate, 3-4 mm. long; corolla rotate; petals 5, about equal to the calyx lobes, obovate to cuneate-obovate, somewhat fringed with minute teeth and stalked glands at the obtuse to rounded apex; stamens 5, inserted near base of corolla tube, the filaments bearded; capsules about 4 mm. in diameter, globose, membranous, circumscissile, many-seeded. Usually in moist places in prairies and flatlands mostly in e. and s. Tex., Mar.-May; nat. from Eur.

7. CENTUNCULUS L. CHAFFWEED

A monotypic genus that is sometimes included in *Anagallis*.

1. *Centunculus minimus* L. Annual, often forming mats or small clumps, the stems erect or ascending, to 12 cm. long; leaves subsessile, alternate, entire, obovate to oblanceolate or oblong-spatulate, to 8 mm. long and 5 mm. wide; flowers sessile in leaf axils, ephemeral, 4- or occasionally 5-merous; sepals linear-lanceolate, about 2 mm. long; corolla rotate, pinkish, about 1 mm. wide, with an urceolate short tube and ovate-lanceolate lobes about half as long as the tube, withering on the apex of the capsule; stamens 4 or 5, inserted near corolla throat, included, the filaments beardless; capsule subglobose, circumscissile, to 2 mm. in diameter. In damp sand and mud in depressions, bogs, grasslands and open woods mainly in e. and s. Tex., Feb.-May; from Fla. to Tex., Calif. and Mex., n. to N.S., O., Ill., Minn. and Sask., nearly cosmopolitan.

FAM. 142. PLUMBAGINACEAE JUSS.

PLUMBAGO FAMILY

Perennial herbs or shrubs, with basal or alternate entire leaves and perfect and regular flowers; calyx inferior, 4- or 5-toothed, sometimes plaited at the sinuses, the tube 5- to 15-ribbed; corolla of 4 or 5 hypogynous clawed segments connate at the base or united into a tube; stamens 4 or 5, opposite the corolla segments, hypogynous; anthers 2-celled, dorsally attached to the filaments, the sacs longitudinally dehiscent; disk none; ovary superior, 1-celled; ovule solitary, anatropous, pendulous; styles 5, fruit a utricle, achene or capsule, enclosed by the calyx; seed solitary.

About 10 genera and 500 species of wide distribution, many in saline or semiarid situations.

1. Acaulescent plants with a leafy caudex, the leaves basal; calyx glabrous or with simple hairs below the middle, glandless; petals with the claws nearly distinct; filaments partly adnate to the petals; styles distinct; fruit an achenelike structure1. *Limonium*, p. 1185.
1. Caulescent plants with alternate leaves; calyx beset with long-stalked glands; petals with the claws united into a slender tube; filaments free; styles united; fruit a capsule2. *Plumbago*, p. 1187.

1. LIMONIUM MILL.¹⁴⁵

SEA-LAVENDER. MARSH-ROSEMARY

Perennials with woody roots and petioled radical thick leaves, the nearly naked erect flowering stems or scapes branched into panicles; flowers solitary or 2 or 3 together in

¹⁴⁵ Adapted partly from S. F. Blake in *Rhodora* 25:55-60. 1923.

several-bracted spikelets that are approximate or scattered on 1-sided branches; calyx funnellform, dry and membranous, persistent; corolla of 5 nearly or quite distinct petals, with long claws, the 5 stamens attached to their bases; styles 5 or rarely 3, separate; fruit membranous and indehiscent, scarcely exerted from the calyx.

About 300 species that are widely distributed. This genus, in North America, is sorely in need of a modern revision.

1. Calyx 4 mm. long or less, the short broadly triangular-ovate lobes spreading at maturity; plants of alkaline flats in Trans-Pecos Texas . . . 1. *L. limbatum*.
1. Calyx 5 mm. long or more, the narrowly ovate-lanceolate lobes erect at maturity; plants of beach and dune areas along the Gulf Coast (2)
- 2(1). Spikelets 1- to 3-flowered, mostly 3 mm. or less apart; calyx usually prominently pubescent on ribs below middle, rarely glabrous . . . 2. *L. Nashii* var. *Nashii*.
2. Spikelets nearly all 1-flowered, mostly 4 mm. or more apart at maturity; calyx glabrous or sparsely short-pubescent near base 2. *L. Nashii* var. *angustatum*.

1. *Limonium limbatum* Small. Plant to 6 dm. high, bluish-green or glaucescent; leaves with petioles to 15 cm. long, obovate to elliptic, rounded or retuse at the barely mucronulate apex, narrowed into the petiole, thick, leathery, venose, to 16 cm. long and 65 mm. wide; scape stout, much-branched from below the middle; panicle large, to 3 dm. wide or more, the branches divergent-ascending, the 2-flowered spikelets densely and distichously aggregated into 1-1.4 cm. long spikes on the ultimate branchlets or somewhat elongated in var. *glabrescens*; outermost bractlet ovate-orbicular to orbicular, acute to acutish, mucronate or apiculate, hyaline-margined, 1-1.4 mm. long; middle bractlet oblong-oval, retuse at apex, hyaline with green midrib, 3 mm. long; innermost bractlet very firm, elliptic, rounded to retuse at apex, hyaline-margined, 3-3.5 mm. long; calyx trumpet-shaped, with wide-spreading limb, about 4 mm. long, with 2 or 3 of the ribs pubescent to the middle and the other ribs generally pubescent only at the extreme base or not at all, the ribs glabrous or nearly so in var. *glabrescens*; calyx lobes deltoid-ovate, obtuse to acute, about 0.7 mm. long; intermediate teeth depressed-deltoid, about 0.2 mm. long or obsolescent; corolla bright-blue. In saline flats and in depressions in the Trans-Pecos, reported from the Panhandle, June-Aug.; also N.M.

The ultimate branchlets of the inflorescence in var. *glabrescens* Correll are somewhat elongated and more laxly flowered than in var. *limbatum*. The calyx ribs are also glabrous or are provided with only a few scattered hairs instead of being densely pubescent as in var. *limbatum*.

2. *Limonium Nashii* Small. Plant 3-8.5 dm. high, the scape solid; leaves with a petiole to 16.5 cm. long, linear-elliptic to narrowly spatulate or obovate, obtuse to rounded at the barely mucronulate apex, narrowed into the petiole, to 17 cm. long and 45 mm. wide; scape paniculately much-branched from near the middle; panicle 2-3 dm. across, the somewhat zigzag lax branches spreading-ascending or arcuate, the ultimate branchlets compactly or loosely flowered; spikelets 1- to 3-flowered; outermost bractlet ovate, acute to acuminate, mucronate, hyaline-margined, 1.8-2.5 mm. long; middle bractlet ovate to oblong, somewhat erose at the obtuse to mucronate apex, hyaline with a distinct midrib, 2.5-4 mm. long; innermost bractlet elliptic, rounded to retuse to subacute at apex, hyaline-margined, 3.8-4.5 mm. long; calyx obconic, glabrous to sparsely or rather densely pilose at extreme base and often on one or two ribs for about half their length, 5-7 mm. long, the whitish 5-lobed limb erect; calyx lobes ovate-lanceolate, acuminate, 1-1.5 mm. long; teeth very short and bifid or obsolescent; corolla violet to lavender; capsule 5-7 mm. long. On beaches, salt flats and marsh borders, in grasslands and in loose sand among dunes along the Gulf Coast, June-Nov.; mostly from S.C., s. to Fla. and w. to Tex. and n.e. Mex., rare n. of S.C.

The inflorescence of this species is more laxly and openly branched than in that of the eastern *L. carolinianum* (Walt.) Britt. Plants ascribed to *L. carolinianum* var. *compactum* Shinnery belong to var. *Nashii*.

In our region var. *angustatum* (Gray) Ahles seems to be more southern in its distribution than var. *Nashii*, being rather frequent on south Padre Island. Its leaf blades are typically smaller than those of var. *Nashii*, being up to about 10 cm. long and 2.5 cm. wide. *L. angustatum* (Gray) Small, *L. carolinianum* var. *angustatum* (Gray) Blake.

2. PLUMBAGO L. LEADWORT

About 12 species that are natives of Eurasia and warm regions in America.

1. *Plumbago scandens* L. **HIERBA DE ALACRÁN, PITILLO.** A perennial woody herb, the brittle branches often elongated and vinelike, glabrous, sometimes 1 m. long; leaves alternate, ovate to elliptic-lanceolate, membranous, glabrous, 3-10 cm. long, acute to acuminate at apex, narrowed at base, the petioles 1 cm. long or less; spikes slender, peduncled, several- to many-flowered, 5-12 cm. long; bracts lanceolate, acuminate, persistent, 4-5 mm. long; calyx tubular, 8-10 mm. long, 5-ribbed, beset with long-stalked glands; corolla white, its filiform tube about 2 cm. long, its obovate mucronate spreading lobes 5-7 mm. long; stamens 5, distinct, the filaments dilated at the base, the anthers linear; styles filiform, stigmatic on the inner side, partly united; capsule linear-prismatic, beaked, about 7 mm. long. In woods, palm groves and thickets in extreme s. Tex., Mar.-Apr.; also s. Fla. and s. Ariz., and widespread in trop. Am.

FAM. 143. SAPOTACEAE JUSS. SAPODILLA FAMILY

Shrubs or trees, commonly spiny and with milky juice; leaves alternate, petiolate, simple, entire, exstipulate, often rusty-downy on lower surface; flowers small, perfect, usually in axillary clusters; calyx free, persistent; fertile stamens usually as many as the lobes of the short hypogynous corolla and opposite them, inserted on its tube along with one or more rows of appendages and scales or staminodes; anthers turned outward; ovary 4- to 12-celled, with a single anatropous ovule in each cell; style single, pointed; fruit drupaceous or baccate, the solitary seed large.

A mostly tropical family of perhaps 40 genera and 800 species.

1. BUMELIA Sw.¹⁴⁶ IRONWOOD

Shrubs or small trees, mostly but not always spiny; leaves often fascicled on short spurs; flowers whitish to yellowish or sometimes greenish, mostly 5-merous; corolla lobes each with a pair of lateral lobes or appendages at base; staminodes petaloid, entire to erose or laciniate; ovary usually somewhat hairy or occasionally glabrous; fruit fleshy, 1-seeded, the seed scar small, nearly basal; endosperm wanting.

About 60 species in the Western Hemisphere, mostly tropical.

- 1. Leaves not conspicuously reticulate-veiny; style more than 2 mm. long 1. *B. celastrina*.
- 1. Leaves closely and conspicuously reticulate-veiny, with the veins evidently raised; style less than 2 mm. long (2)
- 2(1). Leaves finely silvery-strigose or sericeous on lower surface when young, soon glabrate, the larger leaves 4-13 cm. long; sepals and pedicels essentially glabrous; distribution extreme southeast Texas 2. *B. lycioides*.
- 2. Leaves loosely woolly-villous on lower surface, variable in size; sepals and pedicels more or less pubescent (3)
- 3(2). Most of the leaves 5-10 cm. long and more than 2 cm. wide; pedicels mostly much more than 3 mm. long; plants over 5 m. high (4)
- 3. Most of the leaves 2-5 cm. long and less than 2 cm. wide; pedicels rarely more than 3 mm. long; plants seldom over 5 m. high (5)
- 4(3). Lower leaf surface with a thin covering of entangled grayish to somewhat tawny hairs; pedicels sometimes stout and much shorter than the fruit 3. *B. lanuginosa* var. *oblongifolia*.
- 4. Lower leaf surface with a dense covering of less tangled whitish hairs; pedicels usually slender and as long as or longer than the fruit 3. *B. lanuginosa* var. *albicans*.

¹⁴⁶ Adapted from R. B. Clark in Ann. Missouri Bot. Gard. 29:155-182. 1942.

- 5(3). Lower leaf surface with a dense covering of hairs or sometimes only lightly pubescent3. *B. lanuginosa* var. *rigida*.
 5. Lower leaf surface glabrous or only obscurely pubescent or with a few hairs along the midrib3. *B. lanuginosa* var. *texana*.

1. *Bumelia celastrina* H.B.K. LA COMA. A thorny shrub or small tree 2-9 m. tall; leaves with petioles to 1 cm. long, generally fascicled except on vigorous young shoots, glabrous or with only a few very fine inconspicuous white hairs when young, oblanceolate to obovate or sometimes nearly elliptic, broadly rounded at the apex, cuneate at the base, to 4 cm. long and 25 mm. wide, occasionally a little larger, firm, the veins not very prominent, the reticulum rather obscure or indiscernible; flowers 3 to 15 in a cluster, fragrant, the pedicels glabrous or with a few inconspicuous white hairs, to 1 cm. long; corolla 3-4.5 mm. long, the short tube 0.8-1.2 mm. long; anthers 1-1.5 mm. long; staminodes lance-elliptic to rhombic-ovate, 2-3 mm. long; ovary pilose toward the base, glabrous above, the style 2.5-4 mm. long; fruit ellipsoid-cylindric to narrowly obovoid, 7-13 mm. long, blue-black. *B. angustifolia* Nutt. In thickets, along resacas, on gravelly hills and in salt marshes in s. Tex., May-Nov.; from s. Tex., s. to Venez., Fla., Bah. I. and Cuba.

2. *Bumelia lycioides* (L.) Pers. Shrub or small tree to 10 m. tall, often thorny; young twigs glabrous; leaves with petioles to 15 mm. long, mostly elliptic or elliptic-oblanceolate and narrowed to the obtuse to acuminate apex, occasionally obovate and broadly rounded at apex, to 13 cm. long and 5 cm. wide, usually much smaller, pale-green and conspicuously reticulate-veiny on both surfaces, glabrous above, glabrous or more commonly with a few short hairs chiefly along the midrib beneath, the very young leaves more evidently silvery but the pubescence evanescent; flowers numerous, usually 20 or more in a cluster, the pedicels glabrous or slightly hairy and to 1 cm. long; sepals glabrous or with a few reddish hairs within, 1.4-2.9 mm. long; corolla 3.2-4 mm. long, the tube shorter than or sometimes equaling the lobes; anthers 1.2-1.7 mm. long; style 1.1-2 mm. long; ovary short-hairy; staminodes ovate to rhombic-ovate, 1.8-2.4 mm. long; fruit ellipsoid to obovoid or globose, 7-13 mm. long; seeds 6-9 mm. long, commonly tan or light-brown occasionally a little variegated. In low woods and savannahs, rare in s.e. Tex., Apr.-June; from Fla. to Tex., n. to Ark., s. Mo., s. Ind. and s. Va.

Plants with smaller (2-6 cm. long) leaves that are prominently reticulate have been segregated as *B. Smallii* Clark.

3. *Bumelia lanuginosa* (Michx.) Pers., s. *amplo*. COMA. Shrub or small tree to 15 m. or more tall, more or less thorny; leaves oblanceolate to sometimes obovate or elliptic, broadly rounded to sometimes acute at the apex, to 1 dm. long and 35 mm. wide, loosely woolly-villous with white to tawny or rufous hairs when young, soon glabrate above, persistently hairy to sometimes soon glabrate beneath, reticulate-veiny on both sides, sometimes fascicled; flowers more or less numerous in each cluster, the hairy or subglabrous pedicels to 15 mm. long; sepals strongly hairy or nearly glabrous, 1.5-3.2 mm. long; corolla 3-4.7 mm. long, the tube 1.3-2 mm. long; staminodes deltoid-ovate, 1.9-2.7 mm. long, nearly equaling the corolla lobes; anthers 1-1.5 mm. long; ovary pilose; style 1-1.5 mm. long; fruit obovoid to broadly ellipsoid or subglobose, commonly purplish-black, 7-12 mm. long. Mostly in uplands or sometimes in bottomlands from Fla. to Mo. and Kan., s. to Tex., s. Ariz. and n. Mex.

Represented in Texas by 4 varieties separated in the key.

Var. *oblongifolia* (Nutt.) Clark. *B. lanuginosa* subsp. *oblongifolia* (Nutt.) Cronq. var. *oblongifolia* (Nutt.) Clark. In sandy or rocky soils in woods and on hills and along streams in e. and n. Tex., May-July; from w. La. and Tex., n. to s. Mo. and s.e. Kan.

Var. *albicans* Sarg. This is the tallest *Bumelia* in the United States. It may attain a height of 20 m. The dense whitish pubescence, especially on the lower leaf surface, is characteristic. *B. lanuginosa* subsp. *oblongifolia* var. *albicans* Sarg. In woods and on sandy slopes, shell ridges and on rock outcrops in the e. half of Tex., May-July.

Var. *rigida* Gray. The persistent pubescence, somewhat similar to that of var. *albicans*, on the lower surface of the coriaceous leaves is distinctive. *B. rigida* (Gray) Small, *B. lanuginosa* subsp. *rigida* (Gray) Cronq. var. *rigida* Gray. On limestone or gypsum, espe-

cially along bluffs of rivers and streams, mainly on the Edwards Plateau in s.-cen. Tex., Apr.-June; from Tex., w. to s.e. Ariz. and adj. Mex.

Var. *texana* (Buckl.) Cronq. It is entirely possible that this plant should be maintained as a separate species from *B. lanuginosa*. The small, essentially glabrous, heavily veined, coriaceous leaves and slender, short pedicels, as well as the geographic distribution, would tend to support this conclusion. For the present, it is included in the *B. lanuginosa* complex. *B. lanuginosa* subsp. *rigida* var. *texana* (Buckl.) Cronq., *B. texana* Buckl., *B. monticola* Buckl., *B. riograndis* Lundell. On limestone and gypsum, commonly on rimrock or bluffs along streams, in cen. and w. Tex., June-July; from s.w. Okla. and Tex. to n. Mex.

FAM. 144. EBENACEAE GÜRKE

PERSIMMON OR EBONY FAMILY

Trees or shrubs; leaves alternate, entire, deciduous or persistent, exstipulate; flowers small, unisexual, axillary, solitary or in cymes; calyx inferior, the connate segments persistent and accrescent in fruit; corolla urceolate to campanulate or salverform; stamens 3 to many, inserted at base of the corolla; ovary 2- to 16-celled, the ovules usually solitary; fruit baccate, containing several large seeds.

Three genera containing several hundred species, mostly in the Old World.

1. DIOSPYROS L.

PERSIMMON

Shrubs or trees; leaves somewhat persistent or deciduous; flowers unisexual (male and female on separate plants, rarely an occasional flower appearing perfect), axillary, cymose or fasciculate; calyx 4- or 5-lobate; corolla urceolate to campanulate or salverform, the obtuse lobes spreading or recurved; stamens usually 15 or 16; fruit baccate, containing as many as 10 seeds.

Nearly 500 species that comprise the valuable wood ebony and many species with edible fruits, including those in Texas.

1. Ovary and fruit glabrous; fruit yellow to reddish when ripe; leaves petiolate, ovate to elliptic, acute to acuminate, essentially glabrous beneath 1. *D. virginiana*.
1. Ovary and fruit pubescent; fruit black when ripe; leaves subsessile, obovate to oblong-obovate, rounded at apex, hirtellous beneath 2. *D. texana*.

1. *Diospyros virginiana* L. COMMON PERSIMMON. Trees to about 30 m. high, mostly forming a cylindrical or spreading crown, with very hard blackish wood; leaves rather thick, short-petiolate, mostly ovate-oblong, glabrous or nearly so, usually with dark glands or necrotic spots on dorsal surface of the midrib, to about 15 cm. long; peduncles very short; calyx 4-parted; corolla pale yellow, somewhat leathery, campanulate-urceolate, the pistillate corollas 1-1.5 cm. long, the staminate corollas much smaller; styles 4, bilobed at apex; ovary 8-celled; fruit to 5 cm. in diameter, very astringent when green, sweet and edible when ripe (usually after exposure to frost). In dryish woods, old field and clearings mostly in e. Tex. but extending w. to the Rolling Plains, Apr.-June; from Fla. to Tex., n. to N.E., N.Y., Pa., W.Va., O., Ind., Ill., Ia. and Kan.

2. *Diospyros texana* Scheele. TEXAS OR MEXICAN PERSIMMON, BLACK PERSIMMON, CHAPOTE. Shrub or small tree rarely to 16 m. high, with a trunk to 6 dm. thick, the hard compact wood nearly black; bark smooth, thinnish, light reddish-gray, the outer layers peeling off to leave the trunks and stems resembling those of crape-myrtle (*Lagerstroemia*); leaves nearly sessile, coriaceous, broadly ovate to oblong-obovate, rounded or emarginate at apex, to about 5 cm. long, at margin revolute, pubescent beneath; corolla white, sericeous, 8-12 mm. long; fruit black when ripe, about 2 cm. in diameter, the black juicy pulp sweet and edible; seeds 3 to 8. *Brayodendron texanum* (Scheele) Small. In rocky open woodlands, open slopes, arroyos and other such places throughout most of the w. two thirds of Tex. e. to Grimes and Refugio cos., Feb.-June; also Tam., N.L. and Coah.

FAM. 145. STYRACACEAE DUM.

STORAX FAMILY

Shrubs or trees commonly with stellate pubescence; leaves alternate, simple, ~~em~~stipulate; flowers regular, perfect; calyx adherent to the ovary or at least to its base, entire or with 4 to 8 valvate teeth or lobes; corolla with 4 or 5 (rarely more) petals that are (in ours) united at base or rarely more; stamens as many as or several times as many as the corolla lobes, free or adnate to corolla tube; anthers elongate; ovary inferior or partly inferior in *Styrax*; style one; fruit a drupe or capsule.

A small family of about 180 species in 12 genera in warm temperate regions.

- 1. Calyx adherent to whole surface of ovary, corolla 4-lobed; fruit ellipsoid to ellipsoid-obovoid, 2- to 4-winged 1. *Halesia*, p. 1190.
- 1. Calyx adherent only to base of ovary; corolla 5-lobed; fruit globular, wingless 2. *Styrax*, p. 1190.

1. HALESIA ELLIS

Shrubs or small trees, with large veiny deciduous leaves and snowy-white flowers drooping on slender pedicels in clusters or short racemes, the pubescence partly stellate; calyx inversely conical, 4-toothed, the tube ribbed; corolla openly campanulate; petals 4, white, united at base or sometimes to above the middle; stamens 8 to 16; filaments united into a ring at base and usually a little adherent to the base of the corolla; anthers linear-oblong; ovules 4 in each cell; fruit large and dry, bony within; seeds single, cylindrical.

A few species found in North America and China.

- 1. Corolla lobes shorter than the tube; fruit 4-winged 1. *H. carolina*.
- 1. Corolla lobes longer than the tube; fruit 2-winged 2. *H. diptera*.

1. *Halesia carolina* L. CAROLINA SILVER-BELLS, O'POSSUM-WOOD. Large shrubs or small tree to about 12 m. tall; leaves broadly ovate to elliptic or obovate, to 15 cm. long and 8 cm. wide, acute to acuminate, serrulate; flowers in clusters of 2 to 5, with slender pedicels to 15 mm. long; calyx 5-6 mm. long; corolla to 2 cm. long; filaments and styles glabrous; fruit 2.5-4 cm. long, ellipsoid to ellipsoid-obovoid, short-beaked. In rich woods and along stream banks in e. Tex., Apr.-May; from Fla. to Tex. (*vide* Small), n. to Va., W.Va., s. O., s. Ind., s. Ill., s.e. Mo. and Okla.

2. *Halesia diptera* Ellis. SNOWDROP-TREE. Small tree or shrub to 8 m. tall; leaves elliptic to obovate or sometimes ovate, rounded to cuneate at base, abruptly acute to acuminate at apex, when mature essentially glabrous, to 15 cm. long and 9 cm. wide, rather coarsely toothed; calyx 3-4 mm. long, pubescent; corolla 1.5-2 cm. long, copiously pubescent, with pedicels about 1 cm. long; petals broadly elliptic, obtuse; filaments and style pubescent; fruit 3.5-5 cm. long, narrowly ellipsoid, prominently beaked. Woods and along streams in e. Tex., Mar.-Apr.; from n. Fla. n. to S.C., w. to Tex. and Ark.

2. STYRAX L.

STORAX. SILVER BELLS

Shrubs or small trees with deciduous leaves and axillary or leafy-racemed white and showy flowers on drooping peduncles; calyx somewhat 5- to 7-toothed and sometimes glandular at truncate apex; petals soft-downy; stamens twice as many as the corolla lobes; filaments flat, united at the base into a short tube; anthers linear; fruit dry, often 3-valved; seeds globular, erect, with a hard coat.

Over 130 species found in warm regions of North America and Eurasia.

- 1. Leaves characteristically broadly elliptic to obovate; distribution in east Texas 1. *S. americana*.
- 1. Leaves characteristically suborbicular to broadly ovate; distribution in central and west Texas (2)

- 2(1). Pedicels densely and coarsely stellate-pubescent; distribution in Trans-Pecos Texas 2. *S. Youngae*.
- 2. Pedicels merely puberulent; distribution on the Edwards Plateau in central Texas (3)
- 3(2). Both leaf surfaces similar, with scattered stellate hairs to subglabrous 3. *S. platanifolia*.
- 3. Lower leaf surface covered with a fine white puberulence, the upper surface smooth and glossy 4. *S. texana*.

1. *Styrax americana* Lam. **MOCK-ORANGE**. Shrub or small tree to 6 m. tall; leaves elliptic to obovate, tapering to base, more or less abruptly acute to short-acuminate at apex, to 13 cm. long and 8 cm. wide, subglabrous to pulverulent or somewhat scurfy on lower surface, the margins (especially above the middle) irregularly serrulate to serrate-sublobulate; flowers axillary or in several-flowered racemes to 7 cm. long, the racemes subglabrous to scurfy-canescenscent, the pedicels usually about 5 mm. long; calyx puberulent; corolla lobes valvate to somewhat convolute in bud, elliptic to elliptic-oblongate, obtuse to acute at apex, to 15 mm. long and 5 mm. wide; capsule subglobose, about 1 cm. long, apiculate. Incl. f. *pulverulenta* (Michx.) Perkins, *S. pulverulenta* Michx. In moist woods and along streams in e. Tex., Apr.-May; from Fla., w. to Tex., n. to s.e. Va., s. Ind., s.e. Mo., Ark and Okla.

2. *Styrax Youngae* Cory. Shrub to 3 m. tall; leaves orbicular to elliptic, to 5 cm. long and 35 mm. broad, subentire, thin, greenish and densely pubescent with coarse stellate hairs on upper surface, tomentose on lower surface with a fine indumentum and with scattered stellate hairs; flowers in racemose clusters of 3 to 7, with stout pedicels that are densely and coarsely stellate-pubescent; peduncles to 2 cm. long, coarsely stellate-pubescent; calyx campanulate, about 4 mm. long and broad, dark-brown, stellate-pubescent, with the truncate apex inconspicuously toothed; petals 5, narrowly elliptic, obtuse, densely stellate-pubescent, 15-17 mm. long. Apparently endemic in the Davis Mts. of the Trans-Pecos, May.

3. *Styrax platanifolia* Engelm. Shrub or small tree to 4 m. tall, much-branched; leaves more or less pubescent with stellate hairs, rarely subglabrous, strongly reticulate-veined, broadly ovate to suborbicular, with the margins undulate to angulate or occasionally sinuately lobulate, truncate to subcordate at base, obtuse to somewhat abruptly acute at apex, to 1 dm. long and wide; flowers several in corymbose racemes, with puberulent pedicels; calyx puberulent; petals elliptic to elliptic-lanceolate, acute, about 15 mm. long; capsule about 1 cm. in diameter, puberulent, apiculate. Incl. var. *stellata* Cory. Along streams in limestone canyons of Edwards Plateau, Apr.-May; endemic.

4. *Styrax texana* Cory. A spreading slender shrub to 3 m. tall; leaves suborbicular, to 65 mm. long and broad, entire, cuneate to truncate or rounded at base, acute at apex, bright-green and glabrous on upper surface, silvery with a very fine and dense silky-tomentum on lower surface; flowers usually in clusters of 3 to 5, with puberulent pedicels to 1 cm. long; peduncles about as long as the pedicels, often recurved, subglabrate to puberulent; calyx campanulate, about 5 mm. long and 4 mm. wide, densely puberulent and similar in color to the corolla, glandular and 6- to 7-toothed at the truncate apex; petals 5, puberulent, narrowly elliptic, obtuse, to 2 cm. long; fruit globose, about 8 mm. in diameter. Along streams of Edwards Plateau, Apr.-May; endemic.

FAM. 146. SYMPLOCACEAE DESF.

SWEET-LEAF FAMILY

Tree or sometimes shrubs; leaves alternate, simple, without stipules; flowers perfect, regular; calyx campanulate, adherent to the ovary, its lobes valvate or imbricate; corolla with as many as 11 petals (5 in ours) that are united at base; stamens in clusters at the base of each petal, in several series, free or variously united at base; anthers minute, subglobose; ovary partly inferior, 2- to 5-celled; ovules 2 to 4, pendulous; style 1; fruit baccate or drupaceous, crowned by the calyx lobes, 1- to 5-celled, with a solitary anatropous seed in each cell.

Two genera of about 500 species, mostly tropical and subtropical.

1. SYMLOCOS JACQ. SWEET-LEAF

Characters of the family. About 350 species, mostly in tropical regions of both hemispheres.

1. *Symplocos tinctoria* (L.) L'Her. HORSE-SUGAR, YELLOW-WOOD. Large shrubs or small trees to 6 m. tall; leaves elliptic to elliptic-obovate or oblanceolate, tapering to the short petiole, acute to shortly acuminate at apex, subentire to obscurely toothed, usually subcoriaceous and evergreen or late-deciduous, glossy on upper surface, pale and minutely pubescent on lower surface, to 15 cm. long and 6 cm. wide; flowers 6 to 14 in close and bracted clusters on the old wood, yellow, fragrant, the clusters axillary and sessile, opening before or with the leaves; petals 5, obovate, 6-8 mm. long; drupes cylindric-ellipsoid, about 1 cm. long. In woods, swamps and bottomlands in e. Tex., Feb.-Apr.; from Fla. to Tex. and Ark., n. to Del.

The sweetish leaves are much-relished by browsing animals.

FAM. 147. OLEACEAE HOFFMSG. & LINK
OLIVE FAMILY

Trees, shrubs or rarely subherbaceous; leaves opposite or rarely alternate, simple to pinnatifid or pinnate, exstipulate; flowers perfect or unisexual, regular, variously disposed; calyx 4-lobed or -parted, rarely 5- to 16-lobed or wanting; corolla gamopetalous, 4-lobed or rarely 6- to 12-lobed, sometimes of distinct petals or wanting; stamens 2 or rarely 3 to 5, adnate to the corolla and alternate with the lobes; ovary free, 2-celled, with usually 2 ovules in each cell; style 1 or wanting, with a simple or 2-lobed stigma; fruit a drupe, capsule or samara; seeds anatropous, with large straight embryo, with or without albumen.

About 30 genera with over 600 species in temperate and tropical regions. Many ornamental species; a few are of economic importance and some are valuable timber trees. Species of the Old World jasmine (*Jasminum* spp.) are commonly cultivated in our area. They sometimes persist when planted or volunteer. They are climbing or erect shrubs that bear on the ends of the branchlets attractive yellow, white or occasionally reddish flowers with a salver-shaped corolla. The leaves are usually pinnate but may also be reduced to one leaflet.

1. Fruit a samara; leaves pinnately compound (simple in *F. Greggii*) 1. *Fraxinus*, p. 1192.
1. Fruit a capsule or drupe; leaves entire or (if pinnately lobed) the plant less than 3 dm. high (2)
- 2(1). Fruit a didymous thin-walled capsule 2. *Menodora*, p. 1195.
2. Fruit a drupe (3)
- 3(2). Corolla lobes linear, many times longer than the tube, valvate; flowers in pendulous panicles 3. *Chionanthus*, p. 1198.
3. Corolla lobes broad and short or corolla wanting (4)
- 4(3). Flowers in terminal panicles; corolla salverform, well-developed 4. *Ligustrum*, p. 1198.
4. Flowers axillary, in clusters or small racemes; corolla wanting 5. *Forestiera*, p. 1198.

1. FRAXINUS L. ASH

Deciduous trees or very rarely shrubs; winter buds often superposed, with 1 or 2 pairs of outer scales, usually brown or black and scurfy, the outer pair sometimes foliar (that is, obscurely pinnate at apex); leaves opposite, petioled, odd-pinnate, rarely reduced to 1 leaflet; male and female flowers on separate plants or occasional flowers may appear perfect; flowers small, in crowded panicles or racemes; calyx small, 4-parted or -lobed or wanting; corolla of 2 to 6 (usually 4) distinct petals, rarely connate at base or wanting;

stamens usually 2; ovary 2-celled; stigmas 2; fruit a samara or 1-seeded nutlet with a usually elongated wing at the apex; seed oblong, albuminous.

About 70 species in the Northern Hemisphere. Ornamental trees with handsome foliage, some with conspicuous flowers; several species are important timber trees.

1. Plants in the eastern two thirds of Texas from the eastern Panhandle through the central Edwards Plateau south to the Rio Grande Plains and Valley (2)
1. Plants in the western third of Texas, mainly in the Trans-Pecos and western Edwards Plateau (5)
- 2(1). Body of fruit compressed, its broad wing extending to the base; confined to southeast Texas1. *F. caroliniana*.
2. Body of fruit terete or nearly so (3)
- 3(2). Wing of fruit decurrent to about or below the middle of the fruit body; leaves lighter green but not noticeably pale on the lower surface2. *F. pensylvanica*.
3. Wing of fruit terminal or only slightly decurrent on the fruit body; leaves usually pale-glaucous on lower surface, somewhat papillose on upper surface (4)
- 4(3). Leaflets 5 to 9, typically 7, ovate to broadly elliptic or lanceolate, abruptly pointed or acuminate at apex, herbaceous, usually much more than 6 cm. long; fruits usually well over 3 cm. long3. *F. americana*.
4. Leaflets 5 or 7, typically 5, suborbicular-ovate to obovate or sometimes narrowly elliptic, rounded to abruptly acute at apex, often subcoriaceous, usually about 6 cm. long or less; fruits never over 3 cm. long4. *F. texensis*.
- 5(1). Flowers with corolla, in terminal panicles on lateral leafy branchlets of the year; mature leaflets lanceolate to ovate-lanceolate, typically acuminate-attenuate and occasionally cuspidate at apex; confined to the Trans-Pecos region5. *F. cuspidata*.
5. Flowers without a corolla or corolla unknown, unisexual or polygamous, in axillary panicles, from separate buds, in the axils of leaves of the previous year; mature leaflets not acuminate-attenuate or cuspidate, at most simply acuminate (6)
- 6(5). Petiole and leaf rachis more or less winged; leaflets with obscure veins, mostly less than 3 cm. long; distribution Val Verde to Brewster counties6. *F. Greggii*.
6. Petiole and leaf rachis not winged; leaflets with distinct veins, much more than 3 cm. long (7)
- 7(6). Leaves and branchlets glabrous; wing of the fruit decurrent to or near the base of the somewhat compressed fruit body; mainly in the Edwards Plateau and Rio Grande Plains and Valley7. *F. Berlandieriana*.
7. Leaves and branchlets pubescent or glabrous; wing of the fruit (at most) decurrent to above the middle of terete fruit body; mainly in the Trans-Pecos region (8)
- 8(7). Leaflets usually finely pubescent beneath; wing of samara mostly but not always about equaling or shorter than the body8. *F. velutina*.
8. Leaflets glabrous and glaucous beneath; wings of samara longer than the body9. *F. papillosa*.

1. *Fraxinus caroliniana* Mill. CAROLINA ASH, POP ASH, WATER ASH. Shrubby tree rarely more than 10 m. high and trunks to 3 dm. in diameter, the winter buds chestnut-brown; branchlets terete, glabrous or pubescent; leaves with terete petioles; leaflets 5 or 7, with slender petiolules to 2 cm. long, ovate-lanceolate to elliptic or oblong, to 12 cm. long, broadly cuneate or sometimes rounded at the base, acuminate at apex, serrate or rarely entire, pale-green and glabrous or sparingly pilose on the veins or rarely pubescent beneath; anthers linear, apiculate, on slender filaments; samaras rhombic to elliptic or obovate-oblong, 3-5 cm. long, acute to emarginate, the fruit body compressed and surrounded by the wing, sometimes 3-winged. Usually in swamps and along rivers in s.e. Tex., Mar.-May; from Va. to Fla., w. to Ark. and Tex.

2. *Fraxinus pennsylvanica* Marsh. RED ASH. Tree to 20 m. high, with a trunk rarely to 5 dm. in diameter; branchlets and petioles densely pubescent to glabrous; leaflets 5 to 9, with petiolules to about 1 cm. long, ovate to elliptic-oblong or lanceolate, to 15 cm. long, broadly cuneate to somewhat rounded at base, acute to acuminate at apex, the margins entire to serrate, bright-green above, pubescent to glabrous or pubescent only along midrib beneath; panicle rather compact, tomentose to glabrous; anthers linear-oblong, on short filaments; samaras 3-7.5 cm. long, brownish; fruit body slender, terete, to 3 cm. long; wing lanceolate to oblong-obovate, rounded to acuminate or rarely emarginate at apex, decurrent to about or below the middle or very rarely nearly to the base. Along rivers and streams, in alluvial woods and swamps, and in depressions in savannahs, mainly e. of a line drawn from Victoria Co. on the coast to Hemphill Co. on the Rolling Plains in the Panhandle, Feb.-Apr.; from N.S. to Man., s. to Ga., Ala. and Tex.

Our plant is usually referred to var. *integerrima* (Vahl) Fern. [var. *lanceolata* (Buckl.) Sarg.] which is essentially glabrous throughout.

3. *Fraxinus americana* L. WHITE ASH, FRESNO. Tall tree to 40 m. high; young branchlets dark-green or brownish, glabrous and lustrous; leaflets 5 to 9, usually 7, with slender petiolules to 15 mm. long, ovate to ovate-lanceolate or elliptic-lanceolate, to 15 cm. long, cuneate to rounded at the base, mostly acuminate but sometimes blunt at apex, usually entire or only slightly undulate or dentate toward the apex, dark-green above, glaucous beneath and usually glabrous; anthers linear to oblong, apiculate; samaras 3-5 cm. long, the terete fruit body to 15 mm. long; wing narrowly oblong to spatulate, not decurrent, 4-7 mm. broad, emarginate or obtuse at apex. Along streams and in forests in the e. third of Tex., Feb.-Mar.; from N.S. to Minn., s. to Fla. and Tex.

4. *Fraxinus texensis* (Gray) Sarg. TEXAS ASH. Small tree to 15 m. high, essentially glabrous throughout; leaflets 5 or 7, usually 5, with slender petiolules to 2 cm. long, suborbicular-ovate to obovate or sometimes narrowly elliptic, rounded at base, rounded to abruptly acute at apex, 3-8 cm. long or sometimes larger on young trees, crenulate-serrate chiefly above the middle, reticulate on lower surface; samaras 1.5-3 cm. long. *F. americana* var. *texensis* Gray. On bluffs in canyons, on rocky slopes in open woods and about lakes in cen. and n.-cen. Tex., Feb.-Mar.; endemic.

This species is closely allied to *F. americana* and, as Gray did, it probably should be considered as only a variety of that species.

5. *Fraxinus cuspidata* Torr. FRAGRANT ASH, FLOWERING ASH. Shrub or small tree to 6 m. high and 2 dm. in trunk diameter; branches slender, glabrous; bark smoothish, gray, becoming much-fissured into ridges and scaly; winter buds dark-reddish-brown, glutinous; leaves petioled, pinnately compound, to 18 cm. long; leaflets 3 to 9, usually 7, long-petiolulate, ovate to oblong-lanceolate or lanceolate, long-pointed and occasionally cuspidate at apex, 3.5-7 cm. long, essentially entire to coarsely toothed, thin, shiny dark-green above, paler and somewhat pubescent beneath when young; flowers appearing with the leaves, about 13 mm. long, in glabrous clusters 7.5-10 cm. long, fragrant, the whitish corolla 4-parted into linear-oblong lobes; samaras several in clusters, 2-2.5 cm. long, oblong-obovate to rarely lanceolate, the rounded usually emarginate wing 6 mm. wide in upper half and extending nearly to base of flattened fruit body. Scattered and local on rocky slopes of canyons and mts. in the Trans-Pecos, May-June; from w. Tex. to Ariz.

6. *Fraxinus Greggii* Gray. GREGG ASH, LITTLE-LEAF ASH, ESCOBILLA, BARRETA CHINA. Shrub or sometimes a small tree to 6 m. high and 2 dm. in trunk diameter, nearly evergreen; branches slender, terete; bark smooth, thin, gray, the brown wood dark and heavy; leaves pinnately compound, 2.5-4 cm. long, the axis narrowly winged, remaining attached through the winter until after flowering time; leaflets 3 to 7, obovate to oblanceolate, to 35 mm. long, rounded at the apex, inconspicuously toothed, thick and leathery, dark-green above, paler and covered with small black dots beneath; flowers small, partly male and female and partly bisexual, appearing before the new leaves, in small clusters; samaras few in a cluster, spatulate to oblong-obovate, 13-16 mm. long, with a broad linear-oblong wing about 6 mm. wide extending to the base of the short terete fruit body which it greatly exceeds in length, the usually retuse apex of the wing tipped with a very short distinct style. On bluffs, talus slopes, rocky hills and in arroyos and canyons of limestone from Val Verde to Brewster cos., Mar.-May; from Tex. to Ariz.

7. *Fraxinus Berlandieriana* A. DC. MEXICAN ASH, FRESNO. Small tree to about 10 m. high; leaves petiolate, grayish-green to bright-green; leaflets 3 to 5, with petiolules to 12 mm. long, lanceolate to elliptic or obovate, typically narrow, to 12 cm. long, narrowly to broadly cuneate at base, subobtusate to acuminate at apex, nearly entire to coarsely serrate, pale and glabrous or hairy in the axils of the veins beneath; samaras 25-35 mm. long, oblong-obovate to spatulate; wing decurrent to or near the base of fruit body, occasionally 3-winged. Mostly along wooded streams and in canyons in the Edwards Plateau and on the Rio Grande Plains and Valley, s. to Cameron Co., Mar.-Aug.; from Tex. to N.M. and adj. Mex.

8. *Fraxinus velutina* Torr. VELVET ASH, ARIZONA ASH, DESERT ASH, FRESNO. Small to medium-sized tree to 12 m. high and 3 dm. in trunk diameter, with spreading branches to form a rounded crown; bark deeply furrowed into ridges, gray, the light-brown wood soft and heavy; branchlets velvety-tomentose to glabrescent; twigs brown, glabrous to pubescent; leaves petioled, pinnately compound, 7.5-15 cm. long; leaflets 3 to 9, usually 5, short-petiolulate to sessile, varying greatly in appearance, elliptic to lanceolate or ovate, obtuse to long-pointed at apex, 25-75 mm. long, essentially entire to somewhat dentate on upper margins, varying from thin to thick and leathery and from glabrous to densely short-pubescent beneath; flowers small, yellow (staminate) and green (pistillate), appearing before the leaves, many in clusters; samaras numerous in dense clusters, 2-3.5 cm. long; wing oblong-obovate to elliptic or spatulate, shorter than the terete fruit body and decurrent scarcely to the middle, 3-4 mm. wide. Incl. f. *Toumeyii* Britt. and var. *Toumeyii* (Britt.) Rehd., *F. Standleyi* Rehd. In canyons and along streams in the Trans-Pecos, spring; from w. Tex. to Ut., Nev., Calif. and n. Mex.

Similarly to most of our ashes, *F. velutina* is an extremely variable species that has been given a number of names based on its variations. The plant with glabrous branchlets and leaves has been designated as var. *glabra* (Thornb.) Rehd.

9. *Fraxinus papillosa* Lingelsh. Tree to about 6 m. high; leaves 8-15 cm. long, the rachis canaliculate; leaflets subcoriaceous, 5 to 9, essentially sessile, elliptic to elliptic-lanceolate or ovate-elliptic, 3-7 cm. long, 1-3 cm. wide, subobtusate to acuminate, serrulate to subentire, glabrous and glaucous beneath, dull-green above; samaras linear to spatulate, 2.5-3 cm. long, the wing obtuse to emarginate. In canyons and rocky slopes of mts. in Trans-Pecos Tex., Mar.-Apr.; also n. Mex.

Specimens from Presidio Co. have been tentatively identified as this species (*vide* E. L. Little, Jr.). Additional material is needed for complete verification.

2. MENODORA H. & B.¹⁴⁷

Perennial herbs or small shrubs; leaves simple, entire or variously lobed, mostly alternate, exstipulate; flowers perfect, showy, in corymbs, panicles, cymes or occasionally solitary in upper leaf axils; calyx gamosepalous, persistent, prominently lobed; corolla gamopetalous, rotate-campanulate to tubular, yellow or rarely reddish-purple or whitish; stamens 2, inserted on corolla; style filiform, exserted; capsules didymous, thin-walled, circumscissile or indehiscent; seeds 2 or 4 in each cell.

A dozen or more species, mainly in southwestern United States to South America. Plants of this genus are considered to be highly palatable to livestock, and they often constitute an important source of food.

1. Plants diffuse or decumbent; lower leaves cleft; flowers solitary, terminal or axillary; pedicels recurved in fruit 1. *M. heterophylla*.
1. Plants mostly erect; leaves all entire or rarely some slightly lobed; flowers in few- to many-flowered cymes or rarely appearing to be solitary; pedicels erect in fruit (2)
- 2(1). Leaves (at least the upper ones) reduced to bracts, becoming rudimentary; calyx lobes normally 5 or 6 or sometimes with one to several additional reduced lobes ..
..... 5. *M. scoparia*.
2. All leaves foliose, the blades well-developed; calyx lobes 7 or more (3)

¹⁴⁷ Adapted from J. A. Steyermark in Ann. Missouri Bot. Gard. 19:87-176. 1932.

- 3(2). Corolla tube elongated, 25-50 mm. long, salverform, entirely glabrous within4. *M. longiflora*.
3. Corolla tube short, 2.5-7 mm. long, subrotate to shortly infundibuliform, pilose at the orifice (4)
- 4(3). Plants relatively tall; stems much-branched (5)
4. Plants relatively low, subcespitose, flaxlike; stems mostly simple and subherbaceous (6)
- 5(4). Leaves mostly linear or linear-lanceolate3. *M. decemfida* var. *longifolia*.
5. Leaves mostly elliptic-oblong or oblong-lanceolate2b. *M. scabra* var. *ramosissima*.
- 6(4). Leaves mostly linear or linear-lanceolate; corolla lobes oblong to narrowly obovate, obtuse and slightly mucronate2. *M. scabra* var. *scabra*.
6. Leaves mostly ovate to oblong-elliptic or oblong-lanceolate; corolla lobes broadly ovate to subovate, acute and distinctly mucronate2a. *M. scabra* var. *laevis*.

1. *Menodora heterophylla* Moric. Perennial, diffuse, decumbent, subherbaceous, to 25 cm. high; stems numerous, slender, slightly angled, sparsely hispidulous; leaves opposite, slightly petiolate, numerous, crowded, submembranaceous, linear to oblong-lanceolate, acute, entire or pinnately 3- to 7-cleft or -lobed, to 4 cm. long (including the petiole) and 3 cm. broad, the segments linear-lanceolate to obovate, glabrous except for the slightly hirtellous margins; flowers relatively few; pedicels solitary, terminal, slender, 5-8 mm. long, scaberulent, recurved in fruit; calyx campanulate, 6-11 mm. long, the tube 1-3 mm. long, in anthesis about 1.5-2 mm. broad, in fruit 4-5 mm. broad, scaberulent; calyx lobes 10 to 14, linear, acute, entire, 5-10 mm. long, 0.5-1 mm. broad, hirtellous on the margins; corolla shortly infundibuliform, to about 15 mm. long, light-yellow to reddish-purple; corolla tube short, 2-5 mm. long, about 5 mm. broad at the orifice, sparsely pilose near the base of the throat within; corolla lobes 5 or 6, obovate, 6-12 mm. long, 3.5-6 mm. broad, obtuse, slightly mucronate; stamens exerted, 8-10 mm. long; filaments glabrous, connective not conspicuously prolonged at the apex; pistil about 1 cm. long, the stigma capitate; capsule 6-10 mm. long, 1-1.8 cm. broad; seeds 4 in each cell, 5-7 mm. long, about 4 mm. broad, coarsely and rather irregularly reticulated. Rather ubiquitous in cen. and s. Tex., in clay, gravel, sandy loam, on caliche outcrops and rocky hills, and in mesquite pastures, Feb.-Oct.; from Tex., s. to cen. Mex.

2. *Menodora scabra* Gray var. *scabra*. Plant nearly herbaceous, erect, to 35 cm. high; stems numerous, slender, strict, mostly terete, clustered below, simple and elongated above, sparsely to moderately scaberulent or rarely glabrous; leaves opposite or alternate, numerous, crowded, sessile, foliose throughout, linear to linear-lanceolate, the lowest leaves mostly oblong-lanceolate to obovate, to 4 cm. long and 4 mm. broad, entire, acute, subcoriaceous, sparsely hirtellous (especially on the margins and midrib); flowers very numerous, in subcorymbose cymes; pedicels slender, to 2 cm. long, sparsely scaberulent, erect in fruit; calyx campanulate, 4-9 mm. long, somewhat scaberulent; calyx tube 1.5-3 mm. long, in anthesis 1.5-3 mm. broad, in fruit 3-5 mm. broad; calyx lobes 7 to 12, equal or unequal, linear to linear-spatulate, entire, acute to slightly obtuse, 3-7 mm. long, to 0.8 mm. broad, slightly roughened; corolla subrotate, 9-12 mm. long, bright-yellow; corolla tube short, 3-4 mm. long, 2-3 mm. broad at the orifice, pilose at the orifice within; corolla lobes 5, oblong to obovate, obtuse, slightly mucronate, 5-8 mm. long, 3-5 mm. broad, glabrous or sparsely pilose without; stamens exerted, 6-8 mm. long; filaments glabrous, connective prolonged into a short rounded protuberance; pistil about 1 cm. long, the stigma capitate; capsule 5-7 mm. long, 7-12 mm. broad; seeds 4 in each cell, scrobiculate (with small, narrow, deeper irregular pits), seeming smooth to the naked eye, 5-6 mm. long, 4 mm. broad. In sandy, gravelly or clayey soils on rocky hills, river terraces, grassy slopes and mesas in the w. Edwards Plateau and Trans-Pecos, Mar.-Sept.; from s. Colo. to Tex., Ut. and Baja Calif., s. to Dgo.

2a. *Menodora scabra* var. *laevis* (Woot. & Standl.) Steyerem. Leaves (including the petiole) to 17 mm. long and 5 mm. broad, obtuse or acute, distinctly mucronate, glabrous or sparsely scaberulent, the lower and middle ones ovate or elliptic-oblong to oblong-lanceolate, the upper ones becoming lanceolate; pedicels glabrous to moderately

scaberulent; calyx glabrous to slightly roughened; corolla 11-14 mm. long; corolla tube almost entirely glabrous within except for the few slender hairs around the insertion of the filament on the tube; corolla lobes elliptic-obovate to subovate, acute to acuminate, distinctly mucronate; connective of the anther prolonged at the apex into a short sub-cuneate protuberance; seeds 4-5 mm. long, 3-3.5 mm. broad. In arroyos, along creek beds and on slopes in w. Edwards Plateau and Trans-Pecos, Apr.-Aug.; from Tex., w. to s.e. Calif. and Mex.

2b. *Menodora scabra* var. *ramosissima* Steyerl. Plant paniculately branched, erect, suffruticose, to 9 dm. high; stems much-branched but not clustered below; leaves petiolate below, subsessile above, elliptic-oblong to sublanceolate, to 4 cm. long (including the petiole) and 9 mm. broad, submembranaceous, distinctly mucronate, glabrous to sparsely scaberulent; flowers in loose paniculate to subcorymbose cymes; calyx glabrous to densely scaberulent; corolla tube 4.5-5 mm. long; corolla lobes 4.5-6 mm. long; stamens 9-10 mm. long; connective prolonged at the apex into a short cylindrical blunt protuberance; pistil about 1 cm. long; seeds coarsely reticulate with the deeper irregular pits appearing on the surface more frequently than in var. *scabra*, 4.5-5 mm. long, about 3 mm. broad. On gravelly hills and in rocky stream beds in the Trans-Pecos, Aug.-Nov.; from w. Tex. to cen. Ariz. and n. Mex.

3. *Menodora decemfida* (Gill) Gray var. *longifolia* Steyerl. Plants tall, the stems much-branched; leaves (including the petiole) to 4 cm. long, mostly linear to linear-lanceolate, slightly mucronate at apex; calyx 5-11 mm. long, the calyx tube 2-3 mm. long; calyx lobes 8 to 11, 4-8 mm. long; corolla tube 4-5 mm. long; corolla lobes oblong to obovate, 1-1.2 cm. long, 5-8 mm. wide; stamens 11-12 mm. long. In clay and limestone soils in the Trans-Pecos, July-Sept.; from w. Tex. to cen. Mex.

4. *Menodora longiflora* Gray. Plant erect, branching, nearly herbaceous but with woody base, to 9 dm. high; stems very numerous, slender, almost simple and much-elongated to paniculately branched and shortened, slightly angled, glabrous to densely hirsute-pilose; leaves mostly opposite or the uppermost alternate, numerous, sessile to subpetiolate, linear to elliptic-lanceolate or elliptic-oblong, to 55 mm. long and 8 mm. broad, mostly entire, occasionally the lowest 2- or 3-lobed, obtuse to acute or mucronate, glabrous to somewhat hirsute-pilose, subcoriaceous; flowers numerous in terminal sub-corymbose cymes; pedicels slender, to 22 mm. long, glabrous to moderately hirsute-pilose, erect in fruit; calyx campanulate to turbinate, to 23 mm. long, glabrous to somewhat hirsute-pilose; calyx tube 2-3 mm. long, in anthesis 2-3 mm. broad, in fruit 4-6 mm. broad; calyx lobes 8 to 12, equal or unequal, linear, entire and rarely bifid, to 18 mm. long and 1 mm. broad, glabrous to moderately hirsute; corolla bright-yellow, hypercrateriform, 3-6 cm. long; corolla tube 2.5-5 cm. long, 4-5 mm. broad at the orifice, entirely glabrous; corolla lobes 5, ovate, acute, distinctly mucronate, 9-15 mm. long, 5-8 mm. broad; stamens included; filaments glabrous; pistil 2.5-5 cm. long, the stigma broadly capitate; capsule 8-10 mm. long, 1-1.7 cm. broad; seeds 4 in each cell, with large irregular reticulations, 5-7 mm. long, 4-5 mm. broad. *M. hispida* E. J. Palm. In rocky soil and on ledges along streams in canyons on the Edwards Plateau and Trans-Pecos, June-Sept.; from Tex. and s. N.M., s. to cen. Mex.

5. *Menodora scoparia* Engelm. Plant paniculately branching, erect, suffruticose, to 9 dm. high; stems very numerous, much-branched, opposite or clustered at the base, simple and elongated above, strict, slender, slightly angled, mostly glabrous or less often scaberulent; leaves opposite below, subalternate above, relatively few, to 3 cm. long (including the petiole) and 4 mm. broad, entire, acute to obtusish, mostly glabrous or sparsely scaberulent on the margins and upper surface, the well-developed subpetiolate lower leaves slightly crowded and oblong-obovate to oblanceolate, the rudimentary subsessile upper leaves remote and linear or linear-subulate; flowers few, disposed in loose subcorymbose cymes; pedicels slender, to 1 cm. long, erect in fruit, glabrous or sparsely scaberulent; calyx campanulate, 3-6 mm. long, glabrous or sparsely scaberulent; calyx tube 1.5-2.25 mm. long, in anthesis about 2 mm. broad, in fruit about 4 mm. broad, mostly glabrous, rarely sparsely scaberulent; calyx lobes usually 5 or 6 (infrequently with as many as 3 intermediate smaller and narrower lobes), to 4 mm. long and 1 mm. broad, linear to lanceolate, acute to acuminate, entire, mostly glabrous, infrequently sparsely scaberulent on the margins; corolla yellow, subrotate, to about 12 mm. long; corolla tube short, 3-5 mm. long, about 3 mm. broad at the orifice, moderately pilose at

the orifice within; corolla lobes 5, obovate, more or less obtuse, 5-8 mm. long, 3-4 mm. broad; stamens slightly exerted, 7-9 mm. long, connective slightly prolonged into a blunt cylindrical protuberance; pistil to 12 mm. long, the stigma capitate; capsule 4-6 mm. long, about 1 cm. broad; seeds 4 in each cell, ratherly coarsely and regularly reticulate, 4-5 mm. long, about 3 mm. broad. In limestone soils on hills and flats in the Trans-Pecos, June-Aug., from Tex. to s.e. Calif. and n. Mex.

3. CHIONANTHUS L. FRINGE-TREE

Two species, ours and another in eastern Asia.

1. *Chionanthus virginica* L. OLD-MAN'S BEARD. Low deciduous tree to about 10 m. high; branchlets stout, pubescent when young; leaves with petioles to 25 mm. long, opposite to alternate, entire, oval to oblong or oblanceolate, cuneate at base, acute to acuminate at apex, to 2 dm. long and 6 cm. wide, usually much smaller, dark-green and lustrous above, paler and sometimes pubescent beneath; panicles densely flowered, to 2 dm. long, usually leafy-bracted at base; flowers delicate, white or greenish-white, on slender pedicels, opening with or before the leaves, in loose and drooping graceful panicles from lateral buds in the uppermost leaf axils, functionally unisexual; calyx 4-parted, very small, persistent; calyx lobes triangular; petals 1.5-3 cm. long, about 2 mm. wide, narrowly linear, acute, varying to 5 or 6 in number; stamens 2, subsessile on the base of the corolla; style very short, the stigma notched; drupe purple, with a bloom, ovoid to ellipsoid, fleshy, to 18 mm. long. In damp woods, thickets or on bluffs in e. Tex., Mar.-Apr.; from Fla. to Tex., n. to N.J., e. Pa., W.Va., s. O., s. Mo. and Okla.; spreading from cult. northw.

Those plants with pubescent panicles and pubescent lower surface of leaves are usually referred to var. *maritima* Pursh.

4. LIGUSTRUM L. PRIVET

Deciduous or evergreen shrubs or small trees; leaves opposite, short-petioled, entire; flowers perfect, white or yellowish white, in terminal panicles; calyx campanulate, 4-toothed; corolla salverform, with a tubular base and 4 spreading lobes; stamens 2, enclosed or exerted; fruit a usually black or bluish-black 1- to 4-seeded berrylike drupe.

About 50 species in the Old World, many of which are grown for their ornamental foliage.

- 1. Flowers sessile or subsessile, in clusters to form long cylindrical spikes in panicles; corolla tube about as long as the lobes 1. *L. Quihoui*.
- 1. Flowers distinctly pedicelled, in loose panicles; corolla tube shorter than the lobes 2. *L. sinense*.

1. *Ligustrum Quihoui* Carr. WAX-LEAF LIGUSTRUM. Usually evergreen shrub to 2 m. high, with nearly horizontal branches; leaves very short-petioled, glabrous, coriaceous, dark-green, elliptic to obovate or oblanceolate, obtuse at apex, to 5 cm. long; flowers in whorl-like separate clusters at tips of branches and on paired side-branchlets to form an open panicle to 2 dm. long. A nat. of China that has escaped from cult. and become naturalized in woodlands in n.-cen. and e. Tex.

2. *Ligustrum sinense* Lour. CHINESE PRIVET, TRUENO DE SETO. Shrub to 4 m. high, evergreen in mild winters, with spreading branches; leaves short-petioled, rhombic-elliptic to oblong-elliptic or ovate, cuneate at base, broadly obtuse to acute at apex, dull-green above, pubescent on midrib beneath, to 7 cm. long; flowers in loose pubescent panicles to 1 dm. long; calyx pubescent; fruit subglobose, about 4 mm. in diameter. A nat. of China that often persists along fencerows, in thickets and about old home sites.

5. FORESTIERA Poir.

Shrubs or small trees; leaves opposite or subopposite, the phyllotaxis in some species obscured by the foreshortening of the internodes of the twigs ("spurs" or "short shoots");

leaf blades entire, simple, usually porulose (with darkish minute craters scattered in the epidermis); stipules absent; male and female flowers borne on separate bushes or an occasional flower appearing perfect; flowers inconspicuous, borne in small axillary glomerules, unisexual; sepals minute; corolla absent; *staminate flowers* comprising merely 4 (or 5) minute sepals and 4 (or 5) stamens; *pistillate flowers* comprising usually 4 (or 5) minute sepals, 4 (or 5) staminodia and a central stipitate ovary; ovary one-celled, uniovulate; fruit a slow-maturing drupe, longitudinally ribbed prior to ripening, the mesocarp becoming juicy only very shortly before maturity, the exocarp passing through shades of purple to nearly black and with a whitish bloom, the stone thin-walled and made of a series of longitudinal ribs; endosperm copious.

A genus of North America and Central America and the West Indies, of about 12 inclusive species or up to 20 finely divided ones. Plants of the serrate-leaved species are best keyed out in fruiting condition. Some species are among the most sought-after browse in southern and western Texas, and tend to disappear in over-browsed areas. The ripe drupes are eaten by birds.

1. Leaf margins never toothed; blades usually linear 1. *F. angustifolia*.
1. Leaf margins toothed although the teeth sometimes very small; blades not linear (2)
- 2(1). Leaves firm to subcoriaceous, glabrous, apparently persistent; flowers appearing in summer; southern Edwards Plateau and Stockton Plateau 2. *F. reticulata*.
2. Leaves membranous, deciduous, pubescent or glabrous; flowers vernal or autumnal (3)
- 3(2). Leaf blades mostly more than 35 mm. long, basally acuminate, apically acute or acuminate, usually glabrous; petioles usually 5-11 mm. long; eastern half of Texas 3. *F. acuminata*.
3. Leaf blades mostly less than 35 mm. long, basally acute to acuminate, apically acute to rounded, often pubescent; petioles 2-5 mm. long (4)
- 4(3). Leaf blades essentially glabrous above except for minute lines of hairs along the major nervature, beneath softly pubescent; flowers usually appearing in late summer or early fall and fruits maturing in late fall; eastern fourth of Texas 4. *F. ligustrina*.
4. Leaf blades either totally glabrous on both surfaces or with some pubescence on both; flowers vernal; fruit maturing in summer; more western in distribution 5. *F. pubescens*.

1. *Forestiera angustifolia* Torr. DESERT OLIVE, PANALERO. Rounded shrubs with nodes usually crowded on short shoots or well-separated on elongating branches; elongate branches usually arcuate; branchlets glabrous or puberulent; leaf blades linear, 1-3 cm. long, 3-6 mm. broad, not serrate, entirely glabrous or pubescent on one or both surfaces; flowers borne in spring or often after droughts before the new leaves expand. *F. puberula* Eastw., *F. texana* Cory, *F. texana* var. *Palmeri* Cory. Locally abundant in brush, Rio Grande Plains (in coastal areas n.e. to Chambers Co.), n. and w. to Comal, Kinney, Val Verde, Terrell, Brewster and Presidio cos., usually spring; n. Ver., S.L.P., Zac. and Dgo., n. to Tex. and Chih.

The plants from Presidio County and some of them from the Big Bend region in southern Brewster County have minutely puberulent leaf blades, and correspond to the plant described as *F. puberula* (S.L.P., Zac., Coah., Dgo. and Chih.), but the distinction does not seem sufficient to maintain a separate species, and some of the populations of the Chisos Mts. region are mixed. The plants are sought avidly by browsing stock.

2. *Forestiera reticulata* Torr. NETLEAF FORESTIERA. Shrubs; leaves persistent, shiny, serrate, usually somewhat rhombic, with slightly raised venation. *F. racemosa* Wats., *Gymnanthes texana* Standl. Local in limestone tributary canyons of the s. Edwards Plateau and Stockton Plateau, in Bandera, Edwards, Medina, Real, Terrell, Uvalde and Val Verde cos., summer; S.L.P., N.L., Coah. and Tex.

3. *Forestiera acuminata* (Michx.) Poir. SWAMP PRIVET. Shrubs or trees; leaves deciduous, relatively large for this genus, long-petioled and the blades usually acuminate at both ends, rarely pubescent. Incl. f. *vestita* (E. J. Palm.) M. C. Johnst. Infrequent,

lowland woods, e., s.e. and n.-cen. Tex. and as far s. as Victoria and Refugio cos., spring; s.e. U.S., n. to S.C., Tenn., Ind. and Ill., w. to Tex.

4. *Forestiera ligustrina* (Michx.) Poir. Shrub to 4 m. tall; leaves deciduous, the blades mostly 2.5-4 or 6 cm. long, acute basally, apically acute or usually rounded, serrate, above glabrous except for minute pubescence along the main nerves, beneath softly pubescent. *F. autumnalis* Buckl., *F. Wrightiana* Lundell. Infrequent in woods, sandy soils, e. and s.e. Tex., summer-fall; Ala., Ga., Fla., Tenn. and Tex.

5. *Forestiera pubescens* Nutt. ELBOW-BUSH, SPRING HERALD, STRETCH-BERRY. Rounded shrubs with arcuate branches; leaves deciduous, the blades averaging smaller than those of *F. ligustrina* and rather variable in shape, either totally glabrous (var. *glabrifolia* Shinnery, *F. sphaerocarpa* Torr.) or pubescent on both surfaces (*F. neomexicana* Gray). Locally abundant in open pastures and brushy prairies where not too heavily browsed, n.-cen. and Trans-Pecos Tex., Edwards Plateau and Plains Country, spring; Okla. and Tex. w. and s.w. to Calif., Ariz. and the mts. of Chih.

The plants of Oklahoma and most of Texas, including the mountains of the Trans-Pecos, Coahuila and Chihuahua, have blades only about twice as long as broad and are the more typical *F. pubescens*. Those of the western states and from the margin of Salt Flat in Culberson and Hudspeth counties, Texas, and of canyons on the High Plains country have blades about three times as long as broad and are referable to *F. neomexicana*. But there is complete intergradation in western Texas. Alleged differences in pedicel length are fictitious and differences in pubescence are found even in one population. There is no very meaningful way to recognize two species in this complex. Children are known to chew the fruits of this species with ordinary chewing-gum to produce a sort of "bubble-gum."

FAM. 148. LOGANIACEAE MART.

LOGANIA FAMILY

Herbs, vines, shrubs or trees (extra-Texas) with opposite unlobed leaves and stipules or a stipular line or membrane between them; flowers regular, perfect, 4- or 5-merous, gamopetalous, variously arranged; calyx deeply lobed or with separate sepals; corolla salverform to tubular or campanulate; stamens perigynous, as many as the corolla lobes and alternate with them; ovary 2-celled, free from calyx; fruit a capsule or pod. Includes Buddlejaceae and Spigeliaceae.

Traditionally, about 800 species in 30 or more genera in tropical and warm-temperate regions of both hemispheres.

1. Twining woody climbers with semievergreen leaves; flowers axillary; stigmas 4, the apex of style twice 2-cleft1. *Gelsemium*, p. 1201.
1. Erect or spreading herbs or shrubs; flowers in spikes, cymes or panicles, or sometimes axillary or in forks of branches; stigma single, entire or barely 2-lobed (2)
 - 2(1). Flowers 5-merous; corolla valvate in bud; pods didymous or bilobed (3)
 2. Flowers 4-merous; corolla usually imbricated in bud; pods at most notched at apex (4)
 - 3(2). Style single, jointed in the middle; corolla tubular-funnelform or salverform
.....2. *Spigelia*, p. 1201.
 3. Styles 2, short, converging, united at summit and with a common stigma; corolla urceolate3. *Cynoctonum*, p. 1202.
 - 4(2). Calyx lobed to the base; pod loculicidal; herb with diffusely branched stems and linear entire leaves4. *Polypremum*, p. 1202.
 4. Calyx with the lobes more or less united; pod septicidal; shrubs with leaves broad and often dentate (5)
 - 5(4). Corolla mostly rotate-campanulate; anthers sessile or nearly so in the throat of corolla5. *Buddleja*, p. 1202.
 5. Corolla salverform; stamens exerted; filaments elongated, inserted on middle of corolla tube6. *Emorya*, p. 1204.

1. GELSEMIUM JUSS. YELLOW-JESSAMINE

Three species known; two in North America, another in eastern Asia.

1. *Gelsemium sempervirens* (L.) Jaume St.-Hil. CAROLINA-JESSAMINE, POOR MAN'S ROPE. Smooth and twining shrubby perennial; stems high-climbing, wiry, brownish-red; leaves with petioles about 5 mm. long, ovate to elliptic or lanceolate, semievergreen, to 75 mm. long and 3 cm. wide; stipules minute, deciduous; pedicels scaly-bracted; flowers 5-merous, fragrant, in axillary clusters of as many as 6, sometimes solitary; corolla yellow, funnel-form, 25-35 mm. long; anthers oblong, sagittate; style long, slender; pod elliptic, 2-celled and 2-valved, to 15 mm. long, flattened contrary to the narrow partitions; seeds numerous, winged. Usually in sandy loam on edge of or in open woodlands in e. Tex., Feb.-Apr.; from Fla. to Tex., n. to s.e. Va. and Ark.

2. SPIGELIA L. PINK-ROOT. WORM-GRASS

Herbaceous perennials with opposite leaves united by stipules; flowers solitary or in 1-sided cymose spikes, 5-merous; calyx with slender lobes; corolla tubular-funnelform or salverform, with small lobes at summit; anthers linear; style solitary, hairy above and jointed near middle; fruit a 2-celled twin pod that separates into 2 carpels at maturity from a persistent base.

About 50 species in the Western Hemisphere. Segregated by some authors as the basis for a separate family, the Spigeliaceae.

1. Corolla vivid-red on outer surface, yellow within, about 4 cm. long; in east Texas 1. *S. marilandica*.
1. Corolla white or striped, only occasionally more than 1 cm. long; in west-central and south Texas (2)
- 2(1). Corolla 12 mm. long; most leaves 25 mm. long or more 2. *S. texana*.
2. Corolla 8-10 mm. long; most leaves less than 25 mm. long 3. *S. Lindheimeri*.

1. *Spigelia marilandica* L. INDIAN-PINK. Stems simple and erect, to 8 dm. tall; leaves sessile at the broadly rounded base, ovate to ovate-lanceolate, acute to acuminate at apex, to 1 dm. long and 4 cm. wide below middle; flowers showy, in short simple or forked secund spikes; calyx lobes linear-setaceous, serrulate, about 1 cm. long; corolla elongate-tubular, the tube about 4 cm. long, the short lobes lanceolate; anthers and style exserted. On rich wooded slopes in e. Tex., May-Oct.; from Fla. to Tex., n. to Md., O., Ind., Mo. and Okla.

2. *Spigelia texana* (T.&G.) A. DC. TEXAS PINK-ROOT. Plant spreading, with several stems arising at base, nearly smooth and glabrous, to about 3 dm. tall; leaves ovate to elliptic-lanceolate, sometimes obovate or oblanceolate (especially near base of stem), rather thin, 2.5-5 cm. long, to 2 cm. wide, obtuse to acute at apex, broadly tapering at base; flowers terminal and in the axils of leaves; sepals setaceous-subulate, 1-nerved, about 5 mm. long, the margins serrulate-scabrous; corolla salverform, white, about 12 mm. long; anthers and style included; pods 3-4 mm. high. *Coelostylis texana* T. & G. On wooded slopes and floodplain woods along rivers in s. Tex., June-Aug.; endemic.

3. *Spigelia Lindheimeri* Gray. Plant low and diffusely much-branched from base, to about 15 cm. tall, puberulous-scabrous, the stems usually purplish-tinged near base; leaves ovate-elliptic to linear-lanceolate, to about 35 mm. long and 1 cm. wide, obtuse to acute at apex, tapering at base; flowers terminal and arising in the axil of leaves; sepals linear-lanceolate, about 5 mm. long, the scarious margins conspicuously denticulate; corolla salverform, white or sometimes striped, 8-10 mm. long; anthers and style included; pods about 4 mm. high. *Coelostylis Lindheimeri* (Gray) Small. In open gravelly soil and among boulders and about breaks or in prairies on the Edwards Plateau and in s. Tex., Mar.-Apr.; also n. Mex.

3. CYNOCOTONUM J. F. GMEL.

MITERWORT. HORNPOD

Annual smooth herbs with small stipules between the leaves and small whitish or pink-tinged flowers spiked along one side of the branches of a terminal peduncled cyme; flowers 5-merous; sepals ovate to elliptic, united at base; corolla longer than the calyx, somewhat globose-funnelform with small elliptic several-veined lobes; stamens included; ovary slightly adnate to the bottom of the calyx, 2-celled; capsule exserted, strongly bicornute or mitriform, opening down the inner side of each horn, many-seeded.

About 6 species of warm-temperate regions.

1. Capsule 3-4 mm. high, its outer surface essentially smooth; leaves tapering to a petiolate base, typically narrowly elliptic, thin, at least some 3 cm. long or more 1. *C. Mitreola*.
1. Capsule 2-3 mm. high, its outer surface densely cellular-papillose; leaves sessile, typically broadly oval, firm, rarely more than 2 cm. long 2. *C. sessilifolium*.

1. *Cynoctonum Mitreola* (L.) Britt. Stem simple or laxly slender-branched, to 75 cm. tall; leaves thin, petiolate, ovate-elliptic to elliptic or elliptic-lanceolate, obtuse to acuminate at apex, 2-8 cm. long; cymes on long slender peduncles, their branches loosening in fruit; corolla about twice as long as the calyx; fruiting calyces slightly distant; capsules 3-4 mm. high, the outer surface smooth or rarely with few scattered papillae. *Mitreola petiolata* (Walt.) T. & G. In moist soil in seepage, along ditches and streams, and about ponds and lakes in e. and cen. Tex., w. to Val Verde Co. and s.w. to Victoria Co., May-Oct.; from Fla. to Tex., n. to s.e. Va., Tenn. and Ark.

2. *Cynoctonum sessilifolium* (Walt.) J. F. Gmel. Stem stiffly erect, simple or with few erect branches, to about 5 dm. tall; leaves firm, sessile, oval to elliptic or suborbicular-ovate, bluntly obtuse to abruptly tipped, the margin usually noticeably papillose, rarely more than 2 cm. long and wide; cymes more compact than in *C. Mitreola*; corolla only slightly longer than the usually prominently keeled calyx lobes; fruiting calyces approximate; capsules 2-3 mm. high, the outer surface conspicuously and densely cellular-papillose. On seepage slopes and in bogs and wet savannahs, and along wooded streams, in e. Tex., June-Oct.; from Fla. to Tex., n. to s.e. Va.

4. POLYPREMUM L.

A monotypic genus.

1. *Polypremum procumbens* L. A small diffusely much-branched and spreading more or less scabrous annual or perennial to about 3 dm. high; stems several-ribbed; leaves narrowly linear to subulate, to about 3 cm. long, rarely more than 2 mm. wide, connected at base by a slight stipular line; flowers 4-merous, solitary and sessile in the forks and at the ends of the branches; calyx lobes lanceolate-subulate from a broad scarious-margined base, about 3 mm. long, dorsally keeled; corolla white, almost rotate, bearded in the throat, about as long as sepals, the lobes suborbicular and about 1 mm. long; stamens much-abbreviated, the anthers globular; style very short, the stigma entire and ovoid; capsule ovoid, somewhat compressed, notched at apex, about 2 mm. high, 2-celled, loculicidally 2-valved, many-seeded. In dry sandy fields, on dunes, along roadsides and in openings in flatwoods, characteristically weedy, in the e. two thirds of Tex., Apr.-Nov.; from Fla. to Tex., n. to L.I., N.J., e. Pa. and s.e. Mo.; s. to W.I. and Col.

5. BUDDLEJA L.

BUTTERFLY-BUSH

Deciduous or semievergreen shrubs or rarely small trees (extra-Texas) with a glandular, canescent or tomentose indument, or sometimes essentially glabrous; leaves opposite (in ours), sessile or with petioles connected by a transverse stipular line or more evident stipules, entire to crenate or dentate; the usually small 4-merous perfect flowers racemose or crowded into capitate clusters that are variously disposed; calyx campanulate; corolla

tubular to rotate-campanulate, with ovate to orbicular lobes; anthers sessile or nearly so in throat or tube of corolla; pods globose to ellipsoid, bivalved, septicial.

About 100 species in tropical and warm regions of both hemispheres. Segregated by some authors as the basis for a separate family, the Buddlejaceae.

1. Leaves entire to only remotely and inconspicuously serrulate or denticulate (2)
1. Leaves coarsely and prominently crenate or crenate-dentate (3)
- 2(1). Flowers in a dense raceme; corolla usually purplish, about 15 mm. long
 1. *B. Lindleyana*.
2. Flowers in glomerules in axils of uppermost leaves; corolla greenish-yellow, about 5 mm. long 2. *B. sessiliflora*.
- 3(1). Leaves narrowly oblong to linear-cuneate, 1 cm. wide or less, essentially sessile 3. *B. scordioides*.
3. Leaves typically ovate to triangular-lanceolate or somewhat orbicular, more than 1 cm. wide, more or less tapering at the petiole base (4)
- 4(3). Leaves densely tomentose on both surfaces; only in the Trans-Pecos region
 4. *B. marrubiifolia*.
4. Leaves essentially glabrous on upper surface; endemic to Edwards Plateau in central Texas 5. *B. racemosa*.

1. *Buddleja Lindleyana* Fort. Diffusely branched shrub to 2 m. tall, with 4-angled branches; leaves ovate to lanceolate, acuminate, entire to remotely denticulate, glabrous, to 1 dm. long; flowers in upright rather dense spikes to 2 dm. long; corolla purplish to violet or reddish, about 15 mm. long, with the tube slightly curved; capsules 4-5 mm. long. *Adenoplea Lindleyana* (Fort.) Small. Roadsides and cult. ground in s.e. Tex., summer-fall; nat. of China, cult. and escaped to become naturalized in the Coastal Plain from Fla. to Ga. and Tex.

2. *Buddleja sessiliflora* H.B.K. ΤΕΡΟΖΑΝ. Shrub to 2 m. tall or more, moderately tomentose to glabrate throughout; leaves tapering into the distinct petiole, linear-elliptic to lanceolate or sometimes rhombic-ovate, acuminate, entire to remotely serrulate, rather thin, tomentose to glabrous on lower surface, to at least 12 cm. long and 3 cm. wide; glomerules of flowers in axils of uppermost leaves, 10-15 mm. in diameter, short-pedunculate or often essentially sessile with 2 glomerules combined as one; corolla greenish-yellow, fragrant, about 5 mm. long. *B. Humboldtiana* of Coult. On sand bars and banks and in palm groves along the Rio Grande in Cameron and Hidalgo cos., spring-summer; also s. Ariz. and s. to Oax.

3. *Buddleja scordioides* H.B.K. ESCOBILLA, BUTTERFLY-BUSH. Densely branched aromatic shrub to 12 dm. tall, ferruginous-tomentose throughout; leaves essentially sessile, narrowly oblong to linear-cuneate, obtuse, coarsely crenate, rugose, to 45 mm. long and 1 cm. wide, usually much smaller; flowers minute, greenish-yellow to yellowish, in dense clusters that are sessile in the axils of the uppermost leaves, the pair of clusters united around stem to form a globose densely lanate head to 1 cm. broad. In limestone soil and rocky areas in w. Edwards Plateau and the Trans-Pecos, June-Oct.; N.M. and Tex., s. to Jal., Qro. and Hgo.

4. *Buddleja marrubiifolia* Benth. Much-branched shrub to 15 dm. tall; leaves short-petiolate, oval to suborbicular or rhombic, decurrent at the cuneate base, coarsely crenate, densely and velvety tomentose with the dendritic hairs usually ferruginous, to about 5 cm. long and 25 mm. wide, usually much smaller; flowers in dense globose heads (about 12 mm. in diameter) on a short peduncle, yellow to orange-color or reddish, about 3 mm. long. On limestone ledges and slopes in canyons and arroyos of the s. Trans-Pecos, Mar.-Aug.; Tex. and Chih. s. to S.L.P. Subsp. *occidentalis* Norm. is in w. and cen. Chih.

5. *Buddleja racemosa* Torr. WAND BUTTERFLY-BUSH. Small shrub to 5 dm. tall, laxly branched, often essentially glabrous; leaves with a petiole to 1 cm. long, ovate-oblong to triangular-lanceolate, subtruncate to broadly cuneate and often obscurely hastate at base, obtuse to subacuminate at apex, irregularly crenate-dentate, 5-10 cm. long, to about 3 cm. wide, upper surface green and glabrous or vernicose, simply crystalline-granular on lower surface or also provided with a dense tomentum; flower heads subsessile to pedunculate, to 1 cm. broad, in racemes to 3 dm. long; corolla cream-color, only

slightly exceeding the tomentulose calyx. On rocky banks and in crevices of ledges, s. margin of Edwards Plateau, June-Aug.; endemic.

Those plants in the western part of the range with shorter leaves that are densely fulvous-canescens-tomentose on the lower surface have been segregated as var. *incana* Torr. [subsp. *incana* (Torr.) Norm.] The two races overlap in Bexar and Comal counties.

6. EMORYA TORR.

A monotypic genus.

1. *Emorya suaveolens* Torr. A much-branched and somewhat stellately pulverulent scraggly shrub to 2 m. tall; leaves opposite, with petioles to about 1 cm. long, ovate-dehiscoid, obtuse at apex, subhastate at base, sinuate-dentate with a few coarse teeth, minutely whitish-tomentulose beneath, becoming glabrous above, to about 5 cm. long; flowers 4-merous, fragrant, in a narrow pedunculate thyrsoid panicle; calyx tubular, to 15 mm. long, lobed to about the middle, the lobes linear-subulate; corolla salverform, to 35 mm. long, yellow tipped with green; stamens exserted, the filiform filaments inserted on middle of corolla tube; style long, filiform; pod 2-celled, globose to ellipsoid, septical. In Maravillas Canyon near the Rio Grande in Brewster Co. in the Trans-Pecos, July-Oct.; also n. Mex. (Coah. and N.L.)

FAM. 149. GENTIANACEAE JUSS.

GENTIAN FAMILY

Annual or perennial herbs, glabrous or essentially so, with simple exstipulate entire opposite, whorled or rarely alternate sessile to occasionally long-petioled leaves; flowers solitary or borne in clusters or in simple or compound cymes, 4- to 12-merous, regular, perfect, hypogynous, sympetalous; calyx persistent; corolla tubular, salverform, campanulate or rotate; stamens on the corolla tube, alternate and as many as the lobes; ovary 1-celled or essentially 2-celled by intrusion of 2 parietal placentae; style elongate to obsolete, the stigma entire to prominently 2-cleft; capsule usually 2-valved and septical, many-seeded.

A large world-wide family of about 80 genera and 900 species, mostly in temperate regions. By many authors segregated into 2 families, in which case the genus *Nymphoides*, because of its alternate leaves and valvate aestivation, is placed in the Menyanthaceae.

- 1. Leaves alternate, long-petioled, the blade floating; corolla lobes valvate in bud; plant aquatic8. *Nymphoides*, p. 1210.
- 1. Leaves opposite or whorled, sessile or essentially so; corolla lobes never valvate in bud; plant terrestrial (2)
- 2(1). Corolla lobes imbricate in bud, without appendages or glands; calyx lobes 2 or 4, sometimes foliaceous (3)
- 2. Corolla lobes convolute in bud, with or without appendages or glands; calyx lobes 4 or more, not foliaceous (4)
- 3(2). Calyx 4-parted, the segments lanceolate; corolla deeply 4-cleft, slenderly campanulate; stigma nearly sessile6. *Bartonia*, p. 1209.
- 3. Calyx of 2 foliaceous spatulate sepals; corolla 4-lobed, ellipsoid-campanulate; style definite7. *Obolaria*, p. 1210.
- 4(2). Corolla pink to roseate; style filiform, usually deciduous from capsule; anthers either twisted or prominently curved in age (5)
- 4. Corolla never pink (except in one rare form of *Eustoma grandiflorum*), typically lavender, blue or green-purple; style usually stout and persistent; anthers remaining straight or only slightly recurved (6)
- 5(4). Corolla rotate, the tube conspicuously shorter than the lobes; anthers merely recurved or revolute1. *Sabatia*, p. 1205.
- 5. Corolla salverform, the tube exceeding or equal in length to the lobes; anthers spirally twisted2. *Centaurium*, p. 1207.

- 6(4). Corolla lobes without basal glands or intervening appendages or plaits; style slender, subpersistent, with the stigma conspicuously 2-lipped 3. *Eustoma*, p. 1208.
- 6. Corolla lobes not as above; style short and thick, persistent, with the stigma merely 2-cleft (7)
- 7(6). Corolla lobes with intervening appendages or plaits 4. *Gentiana*, p. 1208.
- 7. Corolla lobes with 2 large elliptic pits or nectariferous glands at the base 5. *Swertia*, p. 1209.

1. SABATIA ADANS.¹⁴⁸

ROSE-GENTIAN

Erect glabrous annual or perennial herbs, with slender leafy stems and mostly cymose paniced flowers; leaves mostly cauline but also basal in some species; flowers perfect, regular, long-pedicelled or sessile; calyx gamosepalous, 5- to 12-parted, the lobes slender; corolla 5- to 12-parted, rotate; stamens 5 to 12; filaments slender, inserted on upper edge of corolla tube and alternate with the lobes; anthers basally attached, soon recurved; style slender; stigmatic branches 2; capsule ovoid to cylindric, with numerous seeds.

A genus of 17 species native to continental North America and the West Indies. The name has often been misspelled "Sabbatia."

- 1. Flowers 7- to 12-merous (2)
- 1. Flowers 5- or rarely 6-merous (3)
- 2(1). Flowers several approximate, sessile or nearly so, subtended by foliaceous bracts; annual 1. *S. gentianoides*.
- 2. Flowers solitary on long peduncles, without bracts; perennial 2. *S. dodecandra*.
- 3(1). Calyx tube very prominently 5-nerved and thinly membranous-winged; lateral nerves of the calyx lobes much more strongly developed than the midnerve; flowers 5-merous; annuals (4)
- 3. Calyx tube smooth or finely nerved and lacking membranous wings; midnerve of the calyx lobes almost equaling or even more strongly developed than the lateral nerves; flowers either 5- or rarely 6-merous; annual or perennial (5)
- 4(3). Leaves and calycine lobes thin and membranous, neither succulent nor heavily cutinized; leaves broadest near the base, usually strongly clasping the stem, the midvein at least prominently elevated beneath; calyx lobes usually 2 to 6 times longer than the calyx tube, generally 4 to 8 times longer than broad; corolla lobes typically equaling or exceeding the calyx lobes, usually longer than 1 cm. and wider than 7 mm.; stigmatic lobes over 5 mm. long; anthers longer than 2 mm. ... 4. *S. campestris*.
- 4. Leaves and calycine lobes thick and succulent, heavily cutinized; leaves broadest above the base, tapering somewhat to the sessile nonclasping base, the venation obscure and flush with the surface; calyx lobes usually less than twice the length of the calyx tube, generally less than 4 times as long as broad; corolla lobes usually equaled or exceeded by the calyx lobes, the corolla lobes usually less than 1 cm. long and narrower than 7 mm.; stigmatic lobes less than 5 mm. long; anthers shorter than 2 mm. 5. *S. arenicola*.
- 5(3). Perennial with elongate rhizomes, sometimes stoloniferous; leaves oblong to narrowly obovate; calyx lobes broadened above the middle 6. *S. calycina*.
- 5. Annual without rhizomes or stolons; leaves suborbicular to cordate-ovate; calyx lobes narrowed above the middle 3. *S. angularis*.

¹⁴⁸ Adapted from R. L. Wilbur in *Rhodora* 57:1-36, 43-72, 78-104. 1955.

1. *Sabatia gentianoides* Ell. Erect strict annual to 5 dm. tall; stem usually unbranched or only slightly branched above the middle; leaves dimorphic, thick, the venation obscure, those of the basal rosette wide-spreading and oblong to orbicular-spatulate, to 3 cm. long and 12 mm. wide; cauline leaves linear, strongly ascending or sometimes appressed to the stem, to 1 dm. long and less than 3 mm. wide; flowers subsessile, 7- to 12-merous, borne singly or in clusters of several at apex of main stem or in axils of uppermost leaves, subtended by 2 conspicuously long linear bracts; calyx tube broadly campanulate, smooth and nerveless, to 8 mm. long, the subulate recurved lobes to 15 mm. long; corolla pink to deep-rose-color; corolla lobes elliptic to oblanceolate or spatulate, obtuse to acute, to 3 cm. long and 1 cm. wide; stigmatic lobes 4-7 mm. long; capsule ovoid, to 10 mm. long and 6 mm. in diameter. In boggy or wet pinelands and savannahs in s.e. Tex., May-Aug.; from N.C., s. to Fla. and Tex.

2. *Sabatia dodecandra* (L.) B.S.P. LARGE MARSH-PINK. Perennial to about 7 dm. high, rhizomatous and stoloniferous, with alternate branches or dichotomous above the middle; leaves narrowly elliptic to lanceolate, 2-5 cm. long, obtuse to acute or subacuminate; flowers 8- to 12-merous; calyx lobes lanceolate, 1-3 mm. wide, conspicuously 3- or 5-nerved; corolla lobes pink or whitish, yellow at the base, narrowly oblanceolate to somewhat spatulate, 15-22 mm. long, 4-9 cm. wide. In s.e. Tex., June-Aug.; from S.C. to Tex.

Our plants are referable to var. *foliosa* (Fern.) Wilbur, characterized by having internodes that are equal to or shorter than the subtending leaves, stolons present, and growing in depressions in open woods, about ponds and on stream margins and in ditches. Var. *dodecandra* is typically coastal where it occurs in brackish habitats on the Atl. coast.

3. *Sabatia angularis* (L.) Pursh. ROSE-PINK, BITTER-BLOOM. Erect annual to 7 dm. tall, with simple strongly 4-angled slightly winged stems or bushy-branched; cauline leaves membranous, the lower suborbicular, the middle and upper cordate-ovate, clasping, 3- to 7-nerved, to 3 cm. long and 25 mm. wide; calyx tube about 1.5 mm. long, the thin lobes narrowed above middle and about 1 cm. long; corolla pink or roseate, delicately fragrant; corolla lobes oblong to obovate or elliptic, obtuse, to about 2 cm. long; stigmatic lobes slender, 3-6 mm. long; capsule to 8 mm. long and 5 mm. wide. In open pine-hardwood flats and edge of woods in e. Tex., May-July; N.Y., w. to Ill. and s. to Fla. and Tex.

4. *Sabatia campestris* Nutt. Erect annual to 5 dm. tall, usually much smaller; stem with few or no branches on lower half but with several simple or forking mostly alternate branches above; leaves membranous, oblong-elliptic to broadly ovate-elliptic, obtuse to acute, broadly clasping stem, to 45 mm. long and 2 cm. wide; calyx tube to 8 mm. long, strongly pentagonal with 5 short wing-angles extending up to the sinuses, its 3-nerved lobes linear-lanceolate and to 25 mm. long; corolla roseate to pale-pink or rarely white; corolla lobes broadly obovate to elliptic, obtuse to acute, to 23 mm. long and 15 mm. wide, their yellow basal spots 3- to 6-lobed with 1 or 2 middle lobes longest; stigmatic lobes greenish, becoming yellow with age, 5-8 mm. long; capsule to 9 mm. long. In moist or dry soil in fields, prairies, cedar-oak flats and along streams in e. half of Tex. and s.w. along the coast, Apr.-July; Ill. and Kan., s. to Tex. and Miss.

5. *Sabatia arenicola* Greenm. Erect or erect-spreading annual, to 3 dm. tall; stems simple or branching from the base upward to form a globose intricate mass; leaves thick-succulent, widely spreading, the venation obscured, varying from elliptic-obovate at base to oblong or ovate-lanceolate above, obtuse, to 25 mm. long and 13 mm. wide, usually much smaller; calyx tube to 8 mm. long, strongly pentagonal due to the thick costae or ribs, the thick lobes triangular-lanceolate and to 15 mm. long; corolla roseate to sometimes white; corolla lobes about as long as or shorter than the calyx lobes, obovate to oblong, obtuse; stigmatic lobes greenish, 2.5-4 mm. long; capsule to 9 mm. long. *S. carnosa* Small. On beaches, depressions in dunes, salt flats, fields and savannahs in s. Tex., Apr.-July; in La., Tex. and n.e. Mex.

6. *Sabatia calycina* (Lam.) Heller. Rigidly erect perennial with a slender or thick rhizome, to 4 dm. tall; stems weak, simple or with either opposite or alternate divergent or somewhat ascending branches; leaves membranous, oblong to narrowly obovate, obtuse to acute, to 1 dm. long and 2 cm. wide; flowers usually borne singly, 5- or 6-merous; calyx tube thin, smooth or with the veins only slightly elevated, to 5 mm. long, its thin foliaceous lobes oblanceolate to spatulate and to 3 cm. long; corolla white or

pale-rose to pink; corolla lobes oblanceolate to spatulate or elliptic, obtuse or acute, to 15 mm. long and 6 mm. wide; stigmatic lobes 4-6 mm. long; capsule to 1 cm. long and 8 mm. in diameter. Ditches and shaded river swamps and bottoms in s.e. Tex., June-July; from s.e. Va., s. to Fla. and Tex.; also Cuba and Hisp.

2. CENTAURIUM HILL CENTAURY

Mostly low and small branching annuals but sometimes tall and showy; flowers light-pink to rose-purple or reddish; calyx 4- or 5-parted, the lobes slender and appressed to the corolla tube; corolla funnelform or salverform, with slender tube and 4- or 5-parted limb; anthers exerted, erect, spirally twisting; style slender, single; stigma capitate or bifid.

A genus of about 45 species in temperate regions of the world.

1. Corolla lobes 7 mm. or more long, about as long as the corolla tube (2)
1. Corolla lobes rarely more than 6 mm. long, much shorter than the corolla tube (4)
- 2(1). Some of the leaves oblong or oblong-elliptic; corolla tube and calyx lobes about equal in length 1. *C. calycosum* var.
calycosum.
2. All leaves typically linear; corolla tube conspicuously exceeding the calyx lobes (3)
- 3(2). Plant without minute glands 2. *C. Beyrichii* var. *Beyrichii.*
3. Plant (especially the leaves) densely covered with minute glands
..... 2. *C. Beyrichii* var.
glanduliferum.
- 4(1). Corolla lobes 2 mm. or more wide; at least some of the cauline leaves oblong or oblong-elliptic 1. *C. calycosum* var.
breviflorum.
4. Corolla lobes less than 2 mm. wide; all cauline leaves linear or rarely very narrowly linear-oblanceolate 3. *C. texense.*

1. *Centaurium calycosum* (Buckl.) Fern. var. *calycosum*. ROSITA. Plant erect, simple or corymbosely branched, to 6 dm. tall, usually much smaller; cauline leaves oblong to oblong-elliptic or sometimes narrowly lanceolate, to 6 cm. long and 13 mm. wide; pedicels equaling or sometimes exceeding the calyx; flowers pink to rose-color, rarely white; corolla tube about equaled in length by the oblong to obovate or oval lobes (7-13 mm. long) and the calyx lobes; seeds light-brown. *Erythraea calycosa* Buckl. Usually in moist soil along streams, in prairies and meadows, and on hillsides in cen. and w. Tex., Apr.-June; from Tex. to Mo., w. to Ut., Nev., Ariz. and n. Mex.

The var. *breviflorum* Shinnery of central and south Texas is distinguished from var. *calycosum* by its smaller corolla lobes (5-7 mm. long) and the calyx lobes (6-10 mm. long) being shorter than the corolla tube. It occurs in similar habitats but is also found in salt marshes along the coast.

2. *Centaurium Beyrichii* (T.&G.) Robins. var. *Beyrichii*. MOUNTAIN PINK. Plant slender, to 3 dm. tall, at length fastigiately branched; cauline leaves linear to very narrowly linear-oblanceolate, to 3 cm. long and 3 mm. wide, the uppermost nearly filiform; pedicels about equal to or shorter than the calyx; flowers numerous, pink; corolla tube equal to or somewhat exceeding in length the elliptic to linear-oblong lobes (7-12 mm. long), about half again the length of the calyx lobes; seeds dark-brown. *Erythraea Beyrichii* T.&G. On rocky open limestone slopes and in seepage on granite boulders from n.-cen. to w. Tex., where it is rare, May-Aug.; Tex. and Ark.

The var. *glanduliferum* Correll, of west Texas, is a small much-branched plant about 15 cm. tall. It is distinguished from var. *Beyrichii* by the occurrence of numerous minute glands, especially on the leaves. It also has blackish or very dark-brown seeds.

3. *Centaurium texense* (Griseb.) Fern. LADY BIRD'S CENTAURY.* Plant erect, corymbosely and diffusely branched above, to 3 dm. tall; cauline leaves linear to rarely linear-lanceolate, to 25 mm. long and about 4 mm. wide, the upper leaves reduced to subulate bracts; pedicels about as long as the calyx; flowers small, light-pink; corolla tube about twice the length of the linear-oblong to oblong-elliptic lobes (6 mm. or less long and to

* See Appendix.

1.5 mm. wide), noticeably exceeding the calyx lobes; seeds light-brown. *Erythraea texensis* Griseb. Usually in dry calcareous soils on hills and barrens but occasionally in depressions on granite, on the Edwards Plateau and Blackland Prairies, June-Aug.; from Tex. n. to Mo.

3. EUSTOMA SALISB. CATCHFLY-GENTIAN

Annual or short-lived perennial, more or less glaucous, with erect or ascending leafy stems from a taproot and usually a rosette; leaves opposite, sessile and clasping the stem, entire; flowers long-pedicelled, showy, solitary or paniculate; calyx deeply cleft, the lobes long-attenuate, keeled; corolla deeply campanulate; corolla lobes erect, convolute in bud, the apex entire or somewhat erose and sometimes apiculate; stamens 5 or 6, inserted on the corolla throat; anthers oblong, versatile, straight or recurved; style slender, sub-persistent, with a prominently two-lipped stigma; capsule ellipsoid, 2-valved, many-seeded.

An American genus of several species, mostly in Mexico.

- 1. Corolla lobes 25 mm. long or less, less than 15 mm. wide 1. *E. exaltatum*.
- 1. Corolla lobes usually more than 30 mm. long, mostly 20 mm. or more wide 2. *E. grandiflorum*.

1. *Eustoma exaltatum* (L.) G. Don. Plants to 7 dm. tall, with one or several stems branched above; basal leaves obovate, the cauline leaves oblong to oblong-elliptic and obtuse to subacute, to 9 cm. long and 3 cm. wide; pedicels to 1 dm. long; calyx lobes to 18 mm. long; corolla blue to deep-lavender or white, the tube about 1 cm. long; corolla lobes oblong-obovate, about twice as long as the tube or rarely to 25 mm. long; style slender, about 5 mm. long; stigma lobes about 2 mm. long; capsule to 2 cm. long. *E. silenifolium* Salisb. In damp places in prairies and fields, often in alkaline or saline soils in s. and w. Tex., June-Oct.; in s. U.S., Mex., Br. Hond. and W.I.

The white-flowered plant has been designated f. *albiflorum* Benke.

2. *Eustoma grandiflorum* (Raf.) Shinners. LIRA DE SAN PEDRO, BLUEBELLS. Plants very similar to *E. exaltatum*, to 7 dm. tall; leaves ovate to elliptic-oblong or elliptic-lanceolate, noticeably 3-veined, to 8 cm. long and 3 cm. wide; pedicels to 6 cm. long; calyx to 3 cm. long, the lobes subulate; corolla variously colored blue-purple, pinkish, white or white and purple-tinged or yellowish; corolla lobes 3-4 cm. long, elliptic-obovate, at least 3 times as long as the tube; capsule to 2 cm. long. *E. russellianum* (Hook.) Sweet. In moist places in prairies and fields and about tanks in most of Tex., June-Sept.; Okla. and Tex., w. to Neb. and Colo., s. to Mex.

Several forms have been segregated based on the following flower-colors: white, f. *Fisheri* (Standl.) Shinners; white with purple-tinged lobes, f. *bicolor* (Standl.) Shinners; pink, f. *roseum* (Standl.) Shinners; yellow, f. *flaviflorum* (Cockl.) Shinners.

4. GENTIANA L. GENTIAN

Annual or perennial (in ours) typically glabrous or puberulent herbs with sessile or subsessile entire leaves and showy flowers; flowers 4- or 5-merous, solitary, racemose or cymose; calyx tube campanulate, obconic or tubular; corolla tubular to funnellform, salverform or campanulate, convolute in bud, often with intermediate plaited folds that bear appendages or teeth at the sinuses; stamens inserted on the tube of the corolla; style short or none, the persistent stigmas 2; capsule ellipsoid, 2-valved, the innumerable seeds either borne on placentae at or near the sutures or covering nearly the entire inner face of the capsule.

A large genus of several hundred species found mostly in temperate and cool regions of the world.

- 1. Corolla 3-5 cm. long, blue or whitish; plant essentially glabrous; east Texas 1. *G. Saponaria*.
- 1. Corolla 2-2.5 cm. long, violet-color; plant more or less glandular-ciliolate; west Texas 2. *G. Btgelovii*.

1. *Gentiana Saponaria* L. BOTTLE-GENTIAN, SOAPWORT-GENTIAN. Perennial with a stout caudex and coarse roots, to 8 dm. tall, the stem glabrous or sometimes slightly puberulent in lines; leaves narrowly elliptic to lanceolate, obtuse to acute or occasionally shortly acuminate, abruptly narrowed at base, to 1 dm. long; involucre of 2 to 4 leaves, the outer to 6 cm. long and 2 cm. wide; calyx lobes firm, oblong to oblanceolate or sometimes lanceolate, ascending, to 12 mm. long; corolla blue or whitish, cylindric-oblanceolate, 3-5 cm. long, 1-1.5 cm. in diameter at the slightly open summit, the rounded to subacute lobes erect and only slightly longer than the appendages. In moist woods, thickets and sandy swamps in s.e. Tex., Sept.-Nov.; from Ga. to e. Tex., n. to N.Y., W.Va., Ind., Wisc. and Minn.

2. *Gentiana Bigelovii* Gray. Perennial, glandular-ciliolate throughout (especially on the nerves, calyx and leaf margins), to 3 dm. tall, the slender erect stem leafy; leaves thickish, oblong to oblong-lanceolate, obtuse, to 35 mm. long and 1 cm. wide; flowers 5-merous, short-pedicelled to sessile in upper axils to form a several- to many-flowered leafy-bracted raceme; calyx nearly regular, the tube to 7 mm. long and the slightly irregular linear-subulate lobes about as long; corolla violet-color, cylindrical-funneliform, nearly closed in anthesis, 2-2.5 cm. long, the short lobes acutish; lobes of the plaits triangular, 2-cleft, acute, about half as long as the corolla lobes. Rocky meadows and slopes of high mts. in w. Tex., Aug.-Oct.; from Colo. to w. Tex., N.M. and Ariz.

5. SWERTIA L. GREEN GENTIAN. ELKWEED

A genus of 50 or more species in North America, Eurasia and Africa.

1. *Swertia radiata* (Kell.) O. Ktze. DEER'S-EARS. Stout perennial with mostly simple stems from a thickened taproot, more or less puberulent throughout, to 18 dm. tall, very leafy; leaves in whorls of 4 to 6, the radical and lower cauline leaves obovate to oblong and to 25 cm. long and 4 cm. wide, the uppermost leaves lanceolate and at length linear; flowers numerous in long cymose panicles, 4-merous; calyx lobes linear-lanceolate and to 15 mm. long; corolla greenish-white flecked or irregularly lined with purple, bearing a setaceous lobed crown near the base; corolla lobes broadly elliptic, abruptly acuminate, about 15 mm. long, with a pair of elongate contiguous and densely fringed glands about the middle; fruit ellipsoid-conic, brownish-vernicose, about 2 cm. long; seeds about 5 mm. long. *Frasera speciosa* Hook. In limestone soil in open pine and pine-fir forests and in canyons in the Guadalupe Mts. of w. Tex., June-Oct. from S.D. and Wash., s. to w. Tex., N.M., Calif. and n.e. Mex.

A good browse that is much eaten by deer.

6. BARTONIA MUHL.°

Plants annual or biennial, herbaceous; stem filiform, often somewhat spiraled or twining, mostly green or yellowish; leaves reduced to subulate scales; inflorescence a terminal panicle or raceme of small white to yellowish or purplish 4-merous flowers; calyx cleft to or near the base; corolla campanulate, the lobes about equaling the tube, imbricate in bud; stamens short, inserted at the sinuses of the corolla; anthers oval; style very short and stout; capsule thick-cylindric, flattened, 2-valved; seeds numerous.

Four species confined to the eastern half of North America.

1. Calyx about 3 mm. long; corolla about 5 mm. long, the lobes lanceolate and tapering to an acute to acuminate apex; capsule shorter than the corolla, the style about 1.5 mm. long 1. *B. paniculata*.
1. Calyx 1.5-2 mm. long; corolla about 2.5 mm. long, the lobes elliptic and obtuse to obtuse-apiculate; capsule usually exceeding the corolla, the style about 0.5 mm. long 2. *B. texana*.

1. *Bartonia paniculata* (Michx.) Muhl. SCREW-STEM. Plant glabrous, to about 4 dm. high, with an erect or somewhat twining or flexuous stem; leaves scalelike, alternate or sometimes opposite below; inflorescence usually a short-branched panicle, elongate; pedicels slender, ascending or divergent, about 1 cm. long; flowers to about 5 mm. long; sepals lanceolate, subacuminate, 2-3 mm. long; petals lanceolate, creamy-white, long-

° See Appendix.

acuminate; capsule ellipsoid, usually much shorter than the corolla, the persistent style about 1.5 mm. long. In sandy bogs and meadows in e. Tex., Aug.-Sept.; mostly along the coast from N.S. and N.J., s. to Fla., Okla. and Tex.

2. *Bartonia texana* Correll. Plant inconspicuous, glabrous, to 3 dm. high; stem slender, usually rigidly erect; leaves scalelike, alternate or rarely subopposite, about 1 mm. long; flowers in a slender lax raceme or panicle; pedicels slender, ascending, to 15 mm. long; calyx 1.5-2 mm. long, the lobes triangular-lanceolate and acute; corolla whitish, about 2.5 mm. long, the lobes elliptic and obtuse to obtuse-apiculate; stamens in sinus of petals; capsule ellipsoidal-subquadrate, usually exceeding the corolla, dehiscent at apex by separation of the style, the persistent style about 0.5 mm. long. On sphagnum moss along wooded stream in Tyler Co., s.e. Tex., Sept.-Oct.; endemic.

7. OBOLARIA L. PENNYWORT

A monotypic genus.

1. *Obolaria virginica* L. Herbaceous and succulent purplish-green smooth perennial with a simple or sparingly branched stem from fleshy-thickened saprophytic roots, rarely more than 10 cm. tall; leaves sessile, opposite, cuneate-obovate, to 15 mm. long and about as wide near the apex, reduced to scales on lower part of stem; flowers solitary or in groups of 3, terminal and axillary, nearly sessile; calyx of 2 spatulate spreading sepals that resemble the leaves; corolla white, 4-merous, marcescent, the elliptic-oblong or eventually spatulate lobes (about 5 mm. long) imbricated in bud; stamens short, inserted at the sinuses of the corolla; style short, persistent, the stigma bifid; capsule ovoid, the solitary cell cruciform, the seeds covering entire face of the walls. In humus of low moist hardwoods in e. Tex., Mar.-Apr.; from Fla. to Tex., n. to N.J., Pa., W.Va., O., Ind. and s. Ill.

8. NYMPHOIDES HILL FLOATING-HEART

Perennial submersed aquatic plants with floating leaves on long petioles that bear near their summit an umbel of flowers and often a cluster of short spurlike roots; calyx 5-parted; corolla almost rotate, 5-parted, the lobes bearing a glandular appendage near the base; style short or none, the persistent stigma 2-lobed; capsule few- to many-seeded, at length bursting irregularly; seeds papillate, the coat hard.

A genus of about 20 species; often placed in the segregate family Menyanthaceae.

1. Petioles slender, sometimes with clusters of roots just below the leaf blade; leaves mostly basal; flowers white, in clusters on the petioles 1. *N. aquatica*.
1. Petioles rather stout, without clusters of roots; leaves mostly from branching stems; flowers yellow, axillary 2. *N. peltata*.

1. *Nymphoides aquatica* (Gmel.) O. Ktze. Plant coarse; leaves mostly basal, suborbicular to reniform, with a deep basal sinus, heavy in texture, smooth and yellowish green on upper surface, dark-punctate or pitted on lower surface, to 15 cm. wide; petiole slender, arising from a cluster of fleshy roots, purple-glandular, to 25 cm. or more long; pedicels to 8 cm. long; calyx to 5 mm. long; corolla white, about 15 mm. broad; capsule elongate, to 15 mm. long; seeds glandular-roughened. *Limnanthemum trachyspermum* Gray. In ponds and sluggish streams in e. Tex., May-July; from Fla. and Tex., n. locally to s. N.J. and Del.

2. *Nymphoides peltata* (Gmel.) O. Ktze. YELLOW FLOATING-HEART. Plant coarse; stem stout, extensively creeping and branching; leaves opposite, subtending the umbel, suborbicular, coarsely undulate-dentate, to about 15 cm. long and wide; pedicel often 6 cm. long or more, stout; calyx lobes elliptic-lanceolate, subobtuse, 1 cm. long or more; corolla bright-yellow, 2-3 cm. broad, its segments somewhat fringed; anthers 4-5 mm. long; capsule strongly beaked, to 25 mm. long; seeds flat, narrowly winged, with fringelike margins. In quiet waters of rivers and streams and on wet sandy shores of lakes in n.-cen. Tex., July-Sept.; introd. from Eur. for cult. but escapes and has become established from N.Y. s. to Tex.

FAM. 150. APOCYNACEAE JUSS.

DOGBANE FAMILY

Trees, shrubs, vines or herbs, often with milky juice; leaves opposite or alternate or occasionally verticillate, entire; flowers regular, perfect; calyx gamosepalous, the 5 usually imbricate lobes mostly parted nearly to the receptacle, frequently bearing various glandular appendages within; corolla gamopetalous, varying from salverform or infundibuliform to urceolate or campanulate, the tube sometimes bearing somewhat conspicuous faucal appendages within, the limb 5-parted, the lobes sinistrorsely or dextrorsely contorted in aestivation; stamens 5, alternate with the corolla lobes in the tube, the introrse anthers 4-celled; ovary bicarpellary, the single style surmounted by a massive stigma of diversified structure; fruit follicular (in ours); seeds naked or comose.

About 180 genera and 1,500 species of cosmopolitan distribution. The family contains many ornamental as well as poisonous plants.

- 1. Leaves alternate (2)
- 1. Leaves opposite or whorled (3)
- 2(1). Intricate much-branched shrub; seeds comose; tube of corolla much shorter than its lobes; rare and local in southern Trans-Pecos1. *Haplophyton*, p. 1211.
- 2. Simple or several-branched perennial herbs; seeds naked; tube of corolla mostly at least equaling its lobes; widespread2. *Amsonia*, p. 1211.
- 3(1). Twining vine3. *Trachelospermum*, p. 1215
- 3. Plant erect or trailing, never twining (4)
- 4(3). Trailing evergreen herb; corolla lavender-blue to reddish-purple4. *Vinca*, p. 1215.
- 4. Erect shrubs or perennial herbs; corolla white to scarlet, never bluish (5)
- 5(4). Corolla less than 1 cm. broad5. *Apocynum*, p. 1216.
- 5. Corolla 2 cm. broad or more (6)
- 6(5). Suffrutescent herb or low shrub to about 3 dm. tall, native; inflorescence simple, bearing as many as 3 large flowers6. *Macrosiphonia*, p. 1217.
- 6. Large shrub or small tree more than 3 dm. tall, introduced as ornamental; inflorescence thyriform, bearing numerous flowers7. *Nerium*, p. 1218.

1. HAPLOPHYTON A. DC.

COCKROACH PLANT

Three species are known, all in this hemisphere. An extract of the dried leaves of these plants when mixed with molasses is said to be an effective poison for such insects as cockroaches, flies, mosquitoes, fleas and lice.

1. *Haplophyton Crooksii* L. Benson. Intricate much-branched shrub to about 6 dm. tall; stems and branches green, more or less puberulent with appressed hairs; leaves short-petioled, predominately alternate, occasionally opposite, lanceolate, obtuse to acute at apex, 15-32 mm. long, 4-10 mm. wide, shortly hispid with pustulate hairs; flowers rather showy, solitary or rarely paired in the upper leaf axils; calyx 5-parted, the linear lobes 3-5 mm. long, essentially equal, not imbricate or scarcely so, without squamellae; corolla bright-yellow, salverform, not appendaged within, 7 mm. long or more, pubescent, the limb equally 5-parted, sinistrorsely contorted, longer than the tube; anthers not connivent, without an enlarged connective, wholly included; ovary apocarpous, without a nectary, containing numerous ovules; follicles terete, elongate; seeds black, 6-7.5 mm. long, somewhat grooved and ridged, commonly with part of the surface with broad papillae resembling pebble-grained leather or at least with the ridges broken instead of continuous, comose at apex. On dry rocky slopes in canyons in Presidio Co. in the Trans-Pecos; from w. Tex. to Ariz. and n. Mex.

2. AMSONIA WALT.¹⁴⁹

BLUE-STAR

Caulесcent herbaceous perennials; leaves alternate or subverticillate, not glandular; inflorescence thyriform, terminal or occasionally lateral, bearing several to many flowers;

¹⁴⁹ Ref.: R. E. Woodson, Jr. in N. Am. Fl. 29(2):126-131. 1938.

calyx 5-parted, the lobes essentially equal, scarcely imbricate, without squamellae; corolla salverform, the limb regularly 5-parted, the lobes sinistrorsely contorted; anthers not connivent, without an enlarged connective, wholly included; ovary apocarpous, without a nectary, containing numerous ovules; follicles terete, continuous or more or less moniliform; seeds numerous, naked, rather corky.

A genus of about 25 species in North America and one in Japan.

1. Distribution in eastern one third of Texas; plant usually with upper leaves broader than those below, rarely with linear leaves; corolla never constricted at orifice; follicles slender, continuous or only very slightly articulate (2)
1. Distribution in western two thirds of Texas; plant with all its leaves or at least those on upper half of stems linear to linear-lanceolate or filiform; corolla very rarely not constricted at orifice (6)
- 2(1). Corolla glabrous externally (3)
2. Corolla pubescent externally (4)
- 3(2). Calyx lobes and bracts glabrous; distribution in extreme southeast Texas 1. *A. glaberrima*.
3. Calyx lobes and bracts commonly long-ciliate; distribution in north- and south-central Texas and the Edwards Plateau 2. *A. ciliata*.
- 4(2). Calyx glabrous; leaves thinly membranaceous, opaque above 3. *A. tabernaemontana*.
4. Calyx more or less pilose; leaves firmly membranaceous or subcoriaceous, lustrous above (5)
- 5(4). Stems geniculate at base, from a creeping rootstock, to about 5 dm. tall; leaves not over 3.5 times as long as wide; corolla lobes mostly but not always longer than the tube; in prairies 4. *A. repens*.
5. Stems erect, from a woody rootstock, usually much more than 5 dm. tall; leaves 4 to 6 times as long as wide; corolla lobes rarely longer than the tube; in wet soils of low woodlands, meadows and ditches 5. *A. illustris*.
- 6(1). Corolla tube not constricted at orifice; leaves, bracts and calyx lobes usually with long loose hairs on margins 2. *A. ciliata*.
6. Corolla tube more or less constricted at orifice; leaves, bracts and calyx lobes not as above (7)
- 7(6). Follicles stout, conspicuously articulate-moniliform; stems densely tomentose with white crinkly hairs 6. *A. arenaria*.
7. Follicles slender, continuous, not articulate; stems glabrous or hirtellous with straight hairs (8)
- 8(7). Corolla tube 15 mm. long or less, only slightly constricted at orifice (9)
8. Corolla tube more than 15 mm. long, conspicuously constricted at orifice (11)
- 9(8). Leaves noticeably dimorphic, those on lower half of stems elliptic-lanceolate, those on upper part of stem linear or linear-lanceolate; distribution Pecos County 7. *A. Tharpii*.
9. Leaves not noticeably dimorphic; distribution west of Pecos County (10)
- 10(9). Corolla lobes 3-5 mm. long; plants glabrous or hirtellous; distribution in southern part of Trans-Pecos Texas 8. *A. Palmeri*.
10. Corolla lobes 5-7 mm. long; plants always hirtellous; distribution El Paso County 9. *A. hirtella*.
- 11(8). Plants glabrous; corolla lobes more than 10 mm. long; distribution in Edwards Plateau and eastern Trans-Pecos regions 10. *A. longiflora*.
11. Plants pubescent or very rarely glabrous; corolla lobes less than 10 mm. long; distribution only in Trans-Pecos region 11. *A. salpignanthera*.

1. *Amsonia glaberrima* Woods. Stems to 8 dm. tall, wholly glabrous; leaves alternate, firmly membranaceous, oblong-elliptic to narrowly lanceolate, to 8 cm. long and 2 cm. wide, acuminate, narrowed at the base, wholly glabrous, opaque on both sides, the

petioles 2-4 mm. long; inflorescence rather diffuse, scarcely surpassing the foliage, bearing several to numerous medium-sized azure flowers; pedicels 3-4 mm. long, glabrous; calyx lobes ovate-triangular, acute, about 1.5 mm. long, glabrous; corolla wholly glabrous externally, the tube 6.5-7 mm. long, about 1 mm. in diameter at the base, somewhat dilated above the insertion of the stamens, not constricted at the orifice, the lobes 6-7 mm. long, glabrous, somewhat spreading; follicles relatively slender, continuous, 8-10 cm. long, glabrous. In dense woods and low pinelands in extreme s.e. Tex., Mar.-May; also La.

2. *Amsonia ciliata* Walt. Stems to 15 dm. tall, from woody stolons, more or less densely pilose to glabrate or glabrous; leaves alternate, sessile or subsessile (at least above), oblong-lanceolate to linear-lanceolate or filiform, to 8 cm. long and 1 cm. wide, attenuate at each end, often rather distinctly heterophyllous, frequently with long weak hairs scattered along margins, the lower leaves broader than the upper; inflorescence barely surpassing the foliage, bearing several to numerous medium-sized azure flowers; pedicels 3-5 mm. long, puberulent to glabrate; calyx lobes ovate-lanceolate to linear-lanceolate, long-acuminate, 1-2 mm. long, glabrous or with a few long weak marginal hairs; corolla glabrous externally, the tube 6-8 mm. long, about 1 mm. in diameter at base, somewhat dilated above the insertion of the stamens, not constricted at the orifice, the lobes 7-8 mm. long, glabrous, somewhat spreading; follicles relatively slender, continuous, 9-11 cm. long, glabrous. On limestone and chalky hills, grasslands, along railroad tracks, in sandy loam of prairies and in cedar brakes on the Edwards Plateau and in n.-cen. and s.-cen. Tex., Mar.-May; from N.C., s. to Fla. and Tex.

Vegetatively, this species is highly variable. The following two variants are known to occur in Texas.

Var. *texana* (Gray) Coult. [*A. texana* (Gray) Heller]. Leaves oblong-lanceolate to essentially elliptic above, narrowly elliptic-lanceolate to linear-lanceolate below, 2-6 cm. long, 3-17 mm. wide.

Var. *filifolia* Woods. [*A. ciliata* var. *tenuifolia* (Raf.) Woods.]. Leaves predominantly verticillate, linear-lanceolate to filiform, 2-5 cm. long, 0.5-4 mm. wide.

3. *Amsonia tabernaemontana* Walt. Stems 3-10 dm. tall; leaves alternate, rather thinly membranaceous, ovate to oblong-elliptic or lanceolate, 6-15 cm. long, to 5 cm. broad, acute to acuminate at apex, obtuse to broadly acute at the base, wholly glabrous to finely puberulent beneath, opaque on both sides, the petioles 3-6 mm. long; inflorescence barely surpassing the foliage, bearing several to numerous azure flowers; pedicels 3-6 mm. long; calyx lobes ovate to ovate-lanceolate, 1-2 mm. long, glabrous; corolla more or less pilose externally, the tube 6-8 mm. long, about 1 mm. in diameter at the base, somewhat dilated above the insertion of the stamens, not constricted at the orifice, the lobes 4-7 mm. long, spreading; follicles relatively slender, continuous, 8-12 cm. long, glabrous. In sandy soil about lakes and along streams in n.e. Tex., Mar.-May; from Pa., s. to Ga. and s.w. to Tex.

Those plants with lanceolate to narrowly oblong-elliptic leaves 6-15 cm. long and 1-2.5 cm. wide have been placed in var. *salicifolia* (Pursh) Woods. (var. *Gattingeri* Woods.)

This species, along with *A. glaberrima*, *A. illustris* and *A. repens*, form an extremely close alliance, and it is questionable as to whether or not they should be maintained as separate species rather than variants of one complex unit. The degree of pubescence or lack of pubescence on the corolla and calyx, that mainly separate these entities, is not an entirely reliable characteristic.

4. *Amsonia repens* Shinnars. Stems usually geniculate at base, from a creeping woody rootstock, to about 5 dm. tall; leaves subsessile to shortly petiolate, crowded, lanceolate to elliptic-lanceolate, acute to acuminate, to 6 cm. long and 3 cm. wide, those on middle of stem not over 3.5 times as long as wide; inflorescence equal to or scarcely exceeding the foliage, bearing numerous light indigo-blue flowers; pedicels to 5 mm. long; calyx pilosulous, the subulate lobes about 2 mm. long; corolla pilose externally, the tube to 9 mm. long, not constricted at orifice, the spreading lobes usually longer than the tube; follicles slender, continuous. On prairies and along railroad tracks in e. Tex., Mar.-May; endemic.

5. *Amsonia illustris* Woods. Stems erect, rather stout, from a woody rootstock, to 12 dm. tall; leaves alternate, subcoriaceous to firmly membranaceous, rather narrowly

lanceolate to elliptic-lanceolate, to 1 dm. long and 3 cm. broad, acute to acuminate, cuneate at the base, glabrous, the upper surface lustrous, the petioles 1-4 mm. long; inflorescence barely surpassing the foliage, bearing numerous pale-blue flowers; pedicels 2-8 mm. long; calyx lobes narrowly lanceolate, acuminate, 1.5-3 mm. long, more or less pilosulous; corolla more or less pilose externally, the tube 6-8 mm. long, about 1 mm. in diameter at the base, slightly dilated at the insertion of the stamens, not constricted at the orifice, the lanceolate lobes 5-10 mm. long, spreading; follicles somewhat articulate to essentially continuous, slender, papyraceous, 8-14 cm. long, glabrous. In wet soil of swamps, meadows, low woodlands, and in streams and ditches in the e. third of Tex., Mar.-June; from s. Mo. and e. Kan. to Tex.

6. *Amsonia arenaria* Standl. Plant stoloniferous and forming large colonies; stems 2-5 dm. tall, tomentose with crinkly hairs; leaves sessile, alternate to subverticillate, very narrowly oblong-lanceolate to subfiliform, 4-6 cm. long, 1-5 mm. broad, tomentulose; inflorescence somewhat condensed, barely surpassing the foliage, bearing several to numerous pale-lead-blue flowers; pedicels 0.5-3 mm. long; calyx lobes linear-subulate, 4-8 mm. long, tomentulose; corolla glabrous externally, the clavate tube 8-11 mm. long, about 1.5 mm. in diameter at the base, somewhat inflated at the insertion of the stamens, sharply constricted at the orifice, the oblong-elliptic lobes 5-10 mm. long and spreading; follicles relatively stout, conspicuously articulate-moniliform, 5-8 cm. long, nearly glabrous or inconspicuously puberulent. In sandy soils and sandhills in extreme w. Tex., Apr.-May; from w. Tex. to s.e. Ariz. and Chih.

This species is readily separated from the superficially similar *A. hirtella* and *A. Palmeri* by its crinkly hairs that form a tomentum on the stems.

7. *Amsonia Tharpia* Woods. Perennial suffrutescent herb; stems from heavy woody rootstock, hirtellous, to 2 dm. tall; leaves subsessile, crowded, with scattered hairs to essentially glabrous, dimorphic, those on lower half of stems elliptic-lanceolate, those above linear to linear-lanceolate, acute to acuminate, to 5 cm. long and 12 mm. wide; inflorescence terminal, few-flowered; flowers on pilose pedicels about 3 mm. long; calyx lobes narrowly lanceolate, acuminate, about 3.5 mm. long, pilose; corolla pale-blue or greenish-white, salverform, the tube about 15 mm. long and noticeably constricted at orifice, the spreading elliptic lobes 6-8 mm. long; stamens inserted about 2 mm. below orifice; follicles short, thick, subfusiform, continuous, glabrous, 25-35 mm. long. On limestone hills in Pecos Co. Apr.-May; endemic.

8. *Amsonia Palmeri* Gray. Stems 3-8 dm. tall, glabrous to pubescent with short spreading hairs; leaves alternate, firmly membranaceous, narrowly oblong-lanceolate to linear-lanceolate, to 7 cm. long and 15 mm. broad, acute to acuminate at apex, obtuse or obtusish at the base, glabrous to somewhat pubescent, the petioles 1-3 mm. long; inflorescence very congested, usually well-surpassing the foliage, bearing several to relatively few small pale-lead-blue flowers; pedicels 1 mm. long to nearly obsolete; calyx lobes lance-triangular, acuminate, 3-5 mm. long, densely pilosulous to nearly glabrate; corolla glabrous externally, the tube 10-18 mm. long, about 1 mm. in diameter at the base, somewhat inflated at the insertion of the stamens, slightly constricted at the orifice, the ovate lobes 3-5 mm. long, slightly spreading to essentially erect; follicles slender, continuous, to 12 cm. long, glabrous or nearly so. In sandy or rocky soil in arroyos, draws and small canyons and on low hills in the Trans-Pecos, Mar.-May; also N.M., Ariz. and n. Mex.

This species, that occurs in the southern half of the Trans-Pecos region, is represented by plants that are entirely glabrous, as in the original description, and by plants that are hirtellous as in *A. hirtella*.

9. *Amsonia hirtella* Standl. Herbaceous perennial from a somewhat thickened woody root, usually densely hirtellous; stems to 5 dm. tall, clustered from the base, erect or slightly ascending, freely branched above, the branches ascending or slightly spreading; leaves alternate to subverticillate above, firmly membranaceous, narrowly oblong-lanceolate to linear-lanceolate, to 7 cm. long and 1 cm. wide, acuminate at apex, narrowed to an inconspicuous petiole or practically sessile; inflorescence dense, relatively few-flowered, mostly surpassing the foliage; pedicels 1-3 mm. long; calyx 4-5 mm. long, densely pubescent throughout, the lobes subulate; corolla salverform, the clavate tube constricted at the mouth, 1-1.7 cm. long, the ovate to ovate-oblong lobes 5-7 mm. long and spreading; follicles terete, 6-8 cm. long, stout, glabrous, continuous. *A. Standleyi* Woods. In Tex. only in El Paso Co., Mar.-May; also N.M., Ariz. and Chih.

10. *Amsonia longiflora* Torr. Stems to 6 dm. tall, from a heavy rootstock, glabrous; leaves alternate to subverticillate, membranaceous, sessile or subsessile, linear-lanceolate to filiform, 2-5 cm. long, 1-3 mm. broad, glabrous; inflorescence condensed, well-surpassing the foliage, bearing relatively few showy pale-blue or white flowers; pedicels 2-5 mm. long; calyx lobes linear-subulate, 6-8 mm. long, glabrous; corolla glabrous externally, the tube 3-4 cm. long, about 1.5 mm. in diameter at the base, somewhat inflated over the stamens, sharply constricted at the orifice, the linear-oblong lobes 11-17 mm. long and spreading or reflexed; follicles relatively slender, continuous, 7-15 cm. long, glabrous. On limestone of mesas, arroyos, ravines and open slopes and in clay shales on hills and flats in the Trans-Pecos, Mar.-June; also s. N.M.

11. *Amsonia salpignanthera* Woods. Stems to 35 cm. tall, from a woody rootstock, more or less densely pilose or very rarely glabrous; leaves alternate to subverticillate, membranaceous, sessile or subsessile, linear-lanceolate to subfiliform, to 5 cm. long and 3 mm. broad, pilose to pilosulous or very rarely glabrous; inflorescence barely surpassing the foliage, greatly condensed, bearing several to numerous showy pale-lead-blue or white flowers; pedicels to 7 mm. long, usually pilosulous; calyx lobes linear-lanceolate, acuminate, 4-6 mm. long, pilosulous; corolla glabrous externally, the tube 2.5-4 cm. long, about 1.5 mm. in diameter at the base, somewhat inflated at the insertion of the stamens, sharply constricted at the orifice, the linear-oblong lobes 5-10 mm. long, spreading; follicles slender, continuous, 7-9 cm. long, glabrous. On limestone hills and in rocky canyons and high valleys in the Edwards Plateau and e. Trans-Pecos, Mar.-May; also Chih.

3. TRACHELOSPERMUM LEM.

CLIMBING DOGBANE

About 30 species, all but the following in the Eastern Hemisphere.

1. *Trachelospermum difforme* (Walt.) Gray. Herbaceous twining plant, glabrous to variously puberulent; leaves opposite, with petioles to 12 mm. long, extremely variable and not infrequently heterophyllous on a single plant, thinly membranaceous, elliptic to obovate-elliptic, occasionally linear-elliptic or suborbicular, to 12 cm. long and 75 mm. broad, acuminate at apex (occasionally very shortly and abruptly so), cuneate to rounded at the base; flowers numerous, small, in alternate-axillary thyriform inflorescences; pedicels 4-7 mm. long; calyx 5-parted nearly to the receptacle; calyx lobes ovate-lanceolate, acuminate, 3-4 mm. long, minutely and rather sparsely barbellate at the tips, bearing within alternate pairs of squamellae; corolla pale-yellow, salverform or subinfundibuliform, the tube 5.5-6.5 mm. long, about 1 mm. in diameter at the base, somewhat inflated at the orifice, the 5 lobes obliquely obovate, 3-4 mm. long, dextrorsely contorted, spreading; anthers connivent and agglutinated to the stigma, with an enlarged narrowly 2-lobed connective; ovary apocarpous, containing numerous ovules, surrounded at the base by 5 separate or more or less concrescent nectaries; stigma fusiform, borne upon an elongate style; follicles 2, slender, terete, obscurely undulate-articulate to essentially continuous, 15-23 cm. long, glabrous; seeds many, truncate, comose. Climbing on trees and shrubs along streams, on the edge of forests and in weedy areas in e. Tex., Apr.-June; from Del. s. to Fla. and Tex., w. to Ill., Ind., Mo. and Okla.

4. VINCA L.

PERIWINKLE

Erect or trailing perennial herbs or subshrubs; leaves opposite, not glandular; flowers solitary in alternate axils of leaves; calyx 5-parted, the narrow lobes essentially equal, without squamellae; corolla infundibuliform or salverform, with cylindrical tube and 5 equal lobes twisted to left, hairy or thickened at throat, not appendaged within; anthers not connivent, the connective produced into a relatively large apical appendage, not appendaged at the base; ovary apocarpous, accompanied by two alternate nectaries of nearly equal size, containing numerous ovules; follicles terete, relatively slender; seeds numerous, naked; subcompressed.

About 7 species native to the Old World.

1. Calyx lobes ciliate; leaves broadly rounded to truncate or subcordate at base
 1. *V. major*.
1. Calyx lobes nonciliate, glabrous; leaves narrowed at base
 2. *V. minor*.

1. *Vinca major* L. Trailing evergreen herb, the flowering stems erect and to 3 dm. tall; leaves long-petiolate, ovate, broadly rounded to subcordate at base, obtuse to subacute at apex, ciliate on margins, to 7 cm. long and 5 cm. wide; flowers blue, 2.5-5 cm. across; calyx lobes narrowly linear, about 1 cm. long, long-ciliate; corolla tube funnelform, about 15 mm. long; follicles about 5 cm. long. In sandy soil along streams, on edge of woods and in open woodlands, mostly in e. and cen. Tex., Feb.-Apr.; a nat. of Euras. that escapes cult.

2. *Vinca minor* L. COMMON PERIWINKLE. Creeping or trailing evergreen herb; leaves with petioles 1-2 mm. long, firmly membranaceous to subcoriaceous, elliptic, 1.5-6 cm. long, 8-25 mm. broad, obtuse to broadly acute at apex, somewhat obtusely cuneate to broadly acute at the base, glabrous, somewhat lustrous above, usually minutely glandular-puberulent; flowers solitary in alternate leaf axils, usually on the suberect branches of early spring; pedicels 15-35 mm. long, glabrous; calyx lobes ovate-lanceolate, acute, to 3 mm. long, glabrous; corolla infundibuliform, bright-blue, rarely white, the tube proper 3-6 mm. long, about 1.5 mm. in diameter at the base, the throat conic to conic-campanulate, 5-7 mm. long, 2-3.5 mm. in diameter; follicles slender, 2-7 cm. long, very rarely produced. Nat. of Euras., widely cult. and naturalized throughout the temp. N. Hemis.

5. APOCYNUM L. DOGBANE. INDIAN HEMP

Herbaceous perennials, reproducing freely by horizontal gemmiferous roots, with branching stems; leaves opposite or rarely verticillate, not glandular, often mucronate-pointed; flowers small and pale, on short pedicels in terminal and axillary cymes; calyx 5-parted nearly to the receptacle, without internal squamellae, the lobes equal, scarcely imbricate; corolla campanulate to urceolate or cylindrical, the tube short, the limb regularly 5-parted, with small sagittate appendages at the base opposite the lobes, dextrorsely contorted; stamens on the very base of corolla; anthers connivent and agglutinated to the stigma, with an enlarged narrowly 2-lobed connective; ovary apocarpous, containing numerous ovules, surrounded at the base by 5 distinct ovoid nectaries; stigma usually virtually sessile, variable in shape but essentially ovoid-fusiform; follicles usually 2, separate or somewhat agglutinated at the tips, slender, terete; seeds numerous, truncate, comose.

About 7 species in North America and 70 elsewhere in temperate and tropical regions. The separation of species in this extremely complex genus is not too satisfactory. We have more or less accepted tradition here.

1. Calyx lobes much shorter than the corolla tube at full anthesis, usually less than one half as long as the tube; corolla usually pink or striped with pink, the lobes typically spreading; topmost inflorescence usually exceeding the foliage or leafy branches (2)
1. Calyx lobes (at least some) about as long as the corolla tube, occasionally some longer than or about two thirds as long as the tube; corolla usually whitish or greenish, the lobes mostly erect or nearly so; topmost inflorescence usually exceeded by the foliage or leafy branches (3)
- 2(1). Leaves drooping; corolla 5 mm. long or longer, the lobes noticeably spreading or even recurved at the apex 1. *A. androsaemifolium*.
2. Leaves spreading or ascending, never drooping; corolla 4-5 mm. long, the lobes only slightly spreading 2. *A. medium*.
- 3(1). Leaves noticeably petiolate or only the very lowest sessile, narrowed to broadly rounded at the base, pubescent to glabrous; bracts of inflorescence scarious and aristate 3. *A. cannabinum*.
3. Leaves sessile or nearly so, the lowest cordate at base and usually clasping the stem, always glabrous; bracts of inflorescence more or less foliaceous and laminate
 4. *A. sibiricum*.

1. *Apocynum androsaemifolium* L. SPREADING DOGBANE. Stems erect or ascending to 5 dm. tall, glabrous, freely and rather dichotomously branched; leaves petiolate, drooping, ovate to oblong-lanceolate, mucronate-tipped, to 1 dm. long and 6 cm. broad, dark-green and glabrous above, paler and glabrous to densely tomentulose beneath; cymes terminal and axillary, flowering simultaneously; flowers fragrant; calyx lobes ovate to ovate-lanceolate, 2-5 mm. long, glabrous or rarely minutely pilosulous, rarely half as long as corolla tube; corolla campanulate, 5-12 mm. long, white or pink with pinkish veins in the tube, widely spreading or reflexed, glabrous externally; follicles linear-cylindric, 6-15 cm. long, pendulous at maturity. In dry thickets and edge of woods in the Trans-Pecos, Apr.-July; from Nfld. to B.C., s. to Ga. and Ariz.

2. *Apocynum medium* Greene. Stems erect or ascending to 5 dm. tall, freely and somewhat dichotomously branched (especially below), glabrous to puberulent; leaves petiolate to subsessile, usually spreading, ovate to oblong-lanceolate, obtuse to acute at apex, or cordate-obovate, to 1 dm. long and 2 cm. broad, membranaceous, entire, mucronate, glabrous to somewhat puberulent above, more or less pilosulous to tomentulose beneath; cymes at tip of leafy branches, the central one flowering first; calyx lobes lanceolate to oblong, 1.5-3 mm. long, glabrous to sparsely pilosulous; corolla campanulate to broadly urceolate or cylindric, 3-6 mm. long, the lobes spreading, white or with pinkish veins; follicles 7-15 cm. long, pendulous at maturity. Dry or moist rocky soil in the Trans-Pecos, June-Aug.; from Nfld., s. to N.C., Tex. and N.M.

Those plants that are completely glabrous and whose corollas are cylindrical and have their tube conspicuously larger than the spread of the limb are separated as var. *floribundum* (Greene) Woods.

3. *Apocynum cannabinum* L. INDIAN HEMP. Plant glabrous to variously pubescent; stems erect or ascending to 1 m. tall, glabrous, with ascending branches; leaves petiolate or the lowermost sometimes subsessile, ascending or only slightly spreading, ovate to oblong-elliptic or lanceolate, rounded to acute and usually apiculate at apex, narrowly cuneate to somewhat rounded at base, to 14 cm. long and 7 cm. broad, glabrous above, glabrous to more or less densely pilosulous or tomentulose beneath; calyx lobes lanceolate to ovate-lanceolate, 3-4 mm. long, glabrous; corolla cylindric to urceolate, 3-6 mm. long, white to greenish, the lobes erect or only slightly spreading; follicles 12-20 cm. long, glabrous, pendulous at maturity. Usually in wet or moist sandy or clayey soil in ditches and along streams and rivers, occasionally in fields and open woodlands in e., cen. and n.-cen. Tex., Apr.-Aug.; throughout the U.S. and s. Can.

Those plants that are entirely glabrous throughout are segregated as var. *glaberrimum* A. DC., while those plants that are more or less tomentulose throughout are segregated as var. *pubescens* (R. Br.) A. DC.

4. *Apocynum sibiricum* Jacq. PRAIRIE DOGBANE. Stems erect or somewhat ascending to 7 dm. tall, glabrous throughout, with ascending branches; leaves sessile or subsessile (especially on the main stem) and often with a cordate-clasping base, those on the upper branches frequently shortly petiolate, ascending or slightly spreading, oblong or oblong-lanceolate to oval or rarely linear to linear-lanceolate, to 14 cm. long and 45 mm. wide, obtuse to rounded or cordate at the base; inflorescence usually dense, the bracts usually conspicuous and more or less herbaceous; calyx lobes lanceolate, 2-4 mm. long; corolla urceolate to shortly cylindric, about as long as broad, 3-5 mm. long, white to yellow or greenish, glabrous externally, the lobes erect or slightly spreading; follicles 4-10 cm. long, glabrous, pendulous at maturity. *A. hypericifolium* Ait., ? *A. Suksdorfii* Greene. Usually in sandy soil along creeks and on dunes, and in arroyos and gullies of badlands in n.-cen. Tex., the Edwards Plateau, Plains Country and Trans-Pecos, Apr.-July; throughout most of N.A.

Those plants with the main stem leaves ovate to oval-oblong and deeply cordate and clasping at the base are segregated as var. *cordigerum* (Greene) Fern., while those plants with very narrow leaves and corolla longer than broad are segregated as var. *salignum* (Greene) Fern.

6. MACROSIPHONIA MUELL. ARG.

ROCK-TRUMPET

Suffrutescent herbs or low shrubs; leaves opposite, or rarely verticillate, shortly petiolate to sessile, glandular at the base of the midrib above; inflorescence terminal, rarely sub-

terminal or lateral, usually 1-flowered, rarely with 2 or 3 flowers; calyx 5-parted nearly to the receptacle, the lobes subequal, more or less foliaceous or petaloid, bearing numerous indefinitely distributed squamellae within; corolla infundibuliform, the limb equally 5-lobed, dextrorsely contorted; anthers connivent and agglutinated to the stigma, the enlarged connective obtusely 2-lobed; ovary apocarpous, containing many ovules, surrounded by 5 separate or somewhat concrescent nectaries; stigma relatively massive, umbraculiform-subglochidiate; fruit follicular; seeds numerous, truncate, comose at the apex.

About 10 species, mainly in tropical America.

1. Corolla tube barely as long as the throat or shorter; leaves linear to narrowly oblong 1. *M. hypoleuca*.
1. Corolla tube much longer than the throat; leaves suborbicular to ovate-elliptic 2. *M. Macrosiphon*.

1. *Macrosiphonia hypoleuca* (Benth.) Muell. Arg. Erect or diffuse suffrutescent herb, 1-3 dm. tall; leaves with petioles 1-2 mm. long, narrowly oblong to linear, to 9 cm. long and 2 cm. broad, acute or rarely acuminate or narrowly obtuse at apex, abruptly rounded to truncate at the base, dark-green and hirtellous to glabrate above, much paler and densely tomentulose beneath; inflorescence bearing 1 to 3 white vespertine flowers, the conspicuous peduncle somewhat shorter than the leaves; pedicels 5-10 mm. long; calyx lobes narrowly oblong-lanceolate, acuminate, 5-10 mm. long, somewhat petaloid, minutely puberulent-tomentulose; corolla infundibuliform, finely floccose-tomentulose externally, the tube proper 1-2.5 cm. long, about 1.25 mm. in diameter at the base, the throat narrowly conic or subtubular, 15-25 mm. long, 5-7.5 mm. in diameter at the orifice, the lobes obliquely obovate, 15-25 mm. long, spreading; follicles stout, continuous or slightly articulate, 9-13 cm. long, finely puberulent-papillate. In rocky igneous soil in Davis Mts. in the Trans-Pecos, July-Sept.; also s. to cen. Mex.

2. *Macrosiphonia Macrosiphon* (Torr.) Heller. FLOR DE SAN JUAN. Erect or somewhat diffuse suffrutescent herb, 1.5-3 dm. tall; leaves with petioles to 1 cm. long, ovate-elliptic to suborbicular, to 65 mm. long and 45 mm. broad, at the apex abruptly obtuse or rounded or infrequently acute to somewhat retuse and mucronulate, obtuse to rounded or subcordate at the base, densely tomentulose on both sides; inflorescence bearing a solitary showy white or pink-tinged vespertine flower, the peduncle obsolete or essentially so; pedicel 2-5 mm. long; calyx lobes lanceolate to ovate, acute to acuminate, 1-2 cm. long, 2-5 mm. broad, conspicuously foliaceous, densely tomentulose; corolla infundibuliform, densely puberulent-papillate externally, the tube proper 3.5-9 cm. long, about 1.5 mm. in diameter at the base, the throat narrowly conic to subtubular, 1-2.5 cm. long, 5-7 mm. in diameter at the orifice, the lobes obliquely obovate, 1.5-3 cm. long, spreading; follicles relatively slender, continuous, 10-15 cm. long, puberulent-papillate to glabrate. On dry rocky open or brushy slopes in the Rio Grande Valley, w. Edwards Plateau and Trans-Pecos, May-Sept.; also n. Mex.

7. NERIUM L.

Several species in the Old World. The leaves and flowers are very poisonous if eaten.

1. *Nerium Oleander* L. COMMON OLEANDER, LAUREL ROSA. Shrub or small tree to 5 m. tall or more, essentially glabrous; leaves opposite or in whorls of 3 or 4, very shortly petiolate, coriaceous, oblong-lanceolate, to 3 dm. long and 35 mm. broad, acuminate, narrowly cuneate at the base, lustrous above; inflorescence subcorymbose, much-surpassing the foliage, bearing few to numerous showy flowers of variable color, ranging from scarlet to yellowish-pink or white, and frequently double; calyx 5-parted, the lobes lanceolate to ovate-lanceolate, acuminate, 4-6 mm. long, somewhat foliaceous; corolla infundibuliform, glabrous externally, the tube proper 8-12 mm. long, about 1.5 mm. in diameter at the base, the throat conic-campanulate, 9-10 mm. long, about 7 mm. in diameter at the orifice, the 5 lobes obliquely obovate to obovate-oblong, 2-2.5 cm. long, spreading; follicles 2, separate, relatively stout, 8-15 cm. long; seeds compressed, densely puberulent, comose at apex. Nat. of the Medit. region and the Orient; cult. and widely naturalized in N.A.

FAM. 151. ASCLEPIADACEAE R. BR.¹⁵⁰

MILKWEED FAMILY

Perennial herbs, vines or shrubs with milky juice; leaves opposite, whorled or sometimes alternate, without stipules; flowers perfect, regular, usually umbellate, commonly 5-merous; calyx deeply lobed, the lobes mostly imbricate; corolla 5-lobed or -cleft, the lobes commonly valvate, in bud; a 5-lobed crown is usually present between the corolla and stamens and is adnate to either or both; stamens 5, inserted on the corolla tube usually near its base, the filaments monadelphous or sometimes distinct; anthers united and tipped with a scarious membrane inflexed on the summit of the stylar disk; pollen grains united into waxlike or granular pollinia; carpels 2, with distinct superior ovaries and styles but united above by the peltate discoid stigma; fruit of 2 follicles (or 1 by abortion); seeds many, compressed, usually with long coma.

About 130 genera and 2,000 species widely distributed but most frequent in warm regions.

1. Stamen column or its base surrounded by 5 separate fleshy-inflated or fleshy-thickened erect or spreading appendages (hoods) (2)
1. Stamen column or its base with 1 or 2 rows of flat thin appendages, or a single entire or lobed fleshy disk or cup (3)
- 2(1). Stems prostrate to erect, not twining; base of corolla without a fleshy disk under the separate appendages1. *Asclepias*, p. 1219.
2. Stems twining, at least towards tips; corolla with a fleshy disk at base under the appendages3. *Sarcostemma*, p. 1236.
- 3(1). Appendages thin and flat, in 2 rows or a single entire or lobed fleshy disk or cup4. *Matelea*, p. 1237.
3. Appendages thin and flat, in 1 row (4)
- 4(3). Corolla funnellform or campanulate, 2-6.2 mm. long; wild herbaceous vines or sometimes weeds2. *Cynanchum*, p. 1234.
4. Corolla rotate, its narrowly oblong lobes about 10 mm. or more long; cultivated woody vine5. *Periploca*, p. 1241.

I. ASCLEPIAS L.¹⁵¹

MILKWEED. SILKWEED

Herbs, rarely fruticose or suffruticose, perennial or rarely annual, usually laticiferous; leaves usually decussate, infrequently whorled or irregularly approximate; inflorescence terminal or interpetiolar, umbelliformly cymose, very rarely (*A. Sperryi*) reduced to a solitary flower; calyx lobes 5, equal, divided nearly to the receptacle, bearing few to many minute glandular squamellae within at the base; corolla rotate, the lobes 5, valvate, equal, reflexed, spreading or rarely erect; gynostegium definitely stipitate to sessile; corona of 5 hoods attached to the column and subtending the connivent anthers; hoods cucullate to clavate with various modifications, more or less stipitate to sessile and deeply saccate at the basal attachment to the column, usually bearing an internal horn or crest; anthers 2-celled, with more or less prominent corneous marginal wings enclosing the 5 stigmatic chambers and with membranaceous apical appendages; pollinia paired and pendulous from the translator arms, flat and uniformly fertile, enclosing granular pollen with thin hyaline intine; anther head peltate, more or less pentagonal; fruit follicular, containing many compressed comose or rarely naked seeds.

About 120 species that are native mostly to the Americas.

1. The complete hoods or only their apical portion widespread from the anther head (2)
1. The hoods erect to suberect, more or less parallel to and contiguous with the anther head (6)
- 2(1). Leaves filiform, less than 5 mm. wide (3)
2. Leaves linear-lanceolate or broader, 1 cm. wide or more (4)

¹⁵⁰ Adapted partly from Lloyd H. Shinners in *Sida* 1(6):358-367, 1964.

¹⁵¹ Adapted from R. E. Woodson, Jr. in *Ann. Missouri Bot. Gard.* 41:1-211, 1954.

- 3(2). Base of hoods abruptly deflexed from the anther head, then ascending to an expanded apex 1. *A. Sperryi*.
3. Hoods ascending-spreading, narrowly acuminate at apex 2. *A. macrotis*.
- 4(2). Hoods narrowly attenuate at apex 9. *A. speciosa*.
4. Hoods blunt at apex (5)
- 5(4). Leaves typically lanceolate to linear-lanceolate, narrowly acuminate at apex; distribution in central and west Texas 3. *A. asperula*.
5. Leaves ovate to oblong-lanceolate, obtuse to shortly acute at apex; distribution in eastern half of Texas 4. *A. viridis*.
- 6(1). Leaves typically broad, suborbicular to ovate-elliptic or elliptic (7)
6. Leaves typically narrow, lanceolate to narrowly triangular-lanceolate or linear-lanceolate to filiform (21)
- 7(6). Leaves amplexicaul, clasping the stem at base (8)
7. Leaves petiolate or at most sessile, not clasping the stem (9)
- 8(7). Gynostegium stipitate; distribution east Texas 5. *A. amplexicaulis*.
8. Gynostegium sessile or essentially so; distribution Trans-Pecos Texas 6. *A. elata*.
- 9(7). In natural position the hoods extending at least a third longer than the anther head (10)
9. Hoods shorter than to only slightly longer than the anther head (14)
- 10(9). Hoods noticeably dilated above the middle, repand to emarginate at the broad apex (11)
10. Hoods not dilated above the middle, rounded and sometimes slightly notched at the apex (12)
- 11(10). Hoods 7-10 mm. long, somewhat spreading at tips; corolla lobes 8-14 mm. long 7. *A. oenotheroides*.
11. Hoods about 5 mm. long, not spreading at tips; corolla lobes 6-7 mm. long 8. *A. Emoryi*.
- 12(10). Corolla greenish-yellow to brownish; hoods broadly rounded at apex 10. *A. obovata*.
12. Corolla orange-color to reddish or reddish-purple, rarely clear-yellow; hoods narrowed at apex (13)
- 13(12). Leaves distinctly opposite, distant; petiole more than 5 mm. long; corolla usually reddish-purple 11. *A. purpurascens*.
13. Leaves irregularly approximate, not distinctly opposite, somewhat crowded; petiole 5 mm. long or less; corolla mainly orange-color or reddish 12. *A. tuberosa*.
- 14(9). Gynostegium sessile (15)
14. Gynostegium stipitate (16)
- 15(14). Plants small, 10 cm. or less high; leaves in several approximate pairs near base of stem; corolla purplish-rose; in Texas confined to the mountains of the Trans-Pecos 13. *A. nummularia*.
15. Plants rather tall, usually much more than 15 cm. high; leaves in 6 or more pairs distributed along stem; corolla pale-green; almost entirely east and north of the Trans-Pecos 14. *A. viridiflora*.
- 16(14). Plants small, to 2 dm. high; leaves crowded in several pairs near base of plant; umbel borne at summit of naked scapose stem 15. *A. scaposa*.
16. Plants rather large, typically much more than 2 dm. high; leaves spread along stem; inflorescence not as above (17)

- 17(16). Leaves orbicular to oblong-subquadrate, leathery, usually broadly emarginate at apex and somewhat truncated at base (18)
- 17. Leaves not as above, slightly rounded to cuneate at base, at most thick-membranous (19)
- 18(17). Leaves persistently pubescent, with more or less straight and parallel margins; hoods broadly 2-lobed at tip, the horns not wholly adnate 16. *A. arenaria*.
- 18. Leaves glabrous at maturity, with broadly rounded lateral margins; hoods entire, the horns wholly adnate 17. *A. latifolia*.
- 19(17). Corolla lobes about 3 mm. long; leaves tapering to an acute to acuminate apex; gynostegium with a long slender stipe 18. *A. texana*.
- 19. Corolla lobes 7-10 mm. long; leaves more or less rounded and apiculate at apex; gynostegium with a short stout stipe (20)
- 20(19). Leaves somewhat glaucous and essentially glabrous on lower surface; corolla white; hoods angular on each side near base; horns shorter than hoods 19. *A. variegata*.
- 20. Leaves permanently pubescent on lower surface; corolla pale-yellowish-green and often flushed with orange-color; hoods not angular near base; horns longer than the hoods 20. *A. tomentosa*.
- 21(6). In natural position the hoods extending at least a third longer than the anther head (22)
- 21. Hoods shorter than to only slightly longer than the anther head (27)
- 22(21). Stems prostrate on ground; leaves truncate to shallowly cordate at base 21. *A. prostrata*.
- 22. Stems erect or ascending, not prostrate; leaves rounded to cuneate at base (23)
- 23(22). Hoods noticeably dilated above the middle, repand to emarginate at the broad apex (24)
- 23. Hoods not dilated above the middle, rounded to acutish at apex (25)
- 24(23). Hoods 7-10 mm. long, somewhat spreading at tips; corolla lobes 8-14 mm. long 7. *A. oenotheroides*.
- 24. Hoods about 5 mm. long, not spreading at tips; corolla lobes 6-7 mm. long 8. *A. Emoryi*.
- 25(23). Leaves irregularly approximate, not distinctly opposite, somewhat crowded, more or less pubescent; inflorescences on short peduncles, scarcely if at all surpassing the leaves 12. *A. tuberosa*.
- 25. Leaves distinctly opposite, distant, glabrous; inflorescence on a long naked peduncle (26)
- 26(25). Hoods acute to obtuse at apex; leaves ovate to lanceolate 22. *A. rubra*.
- 26. Hoods broadly rounded at apex; leaves linear-lanceolate 23. *A. lanceolata*.
- 27(21). Leaves filiform to linear-filiform, all of them 4 mm. wide or less (28)
- 27. Leaves ovate or broadly elliptic to linear or linear-lanceolate, typically most of them more than 5 mm. wide (34)
- 28(27). Hoods sharply erose or 2-lobed at apex (29)
- 28. Hoods entire at apex, not erose or lobed (30)
- 29(28). Gynostegium with a short stout stipe; distribution in the Trans-Pecos 24. *A. quinquedentata*.
- 29. Gynostegium sessile; distribution northeast Texas 25. *A. stenophylla*.
- 30(28). Gynostegium sessile; hoods deeply saccate and excurrently auriculate at the base, broadly truncate or retuse at apex 26. *A. Engelmanniana*.
- 30. Gynostegium distinctly stipitate; hoods not as above (31)

- 31(30). Leaves opposite or very rarely 3 at some nodes ... 27. *A. linearis*.
 31. Leaves verticillate or spirally approximate (32)
 32(31). Plants small, mostly less than 25 cm. high; leaves numerous, crowded, spirally approximate; distribution Texas Panhandle 28. *A. pumila*.
 32. Plants tall, mostly 30 cm. or more high; leaves verticillate; distribution mostly south of the Panhandle (33)
 33(32). Leaves more or less heterophyllous at the nodes, rather lax and spreading, often longer than 8 cm.; stems usually with dwarf vegetative branches bearing reduced opposite leaves; distribution west Texas 29. *A. subverticillata*.
 33. Leaves all similar at the nodes, usually rather strictly ascending; stem without dwarf branches; distribution eastern half of Texas 30. *A. verticillata*.
 34(27). Gynostegium sessile or *A. involucrata* with very short stout stipe (35)
 34. Gynostegium with a rather slender distinct stipe (37)
 35(34). Plants small, 25 cm. tall or less, the stems spreading; hoods usually slightly exceeding the anther head 31. *A. involucrata*.
 35. Plants usually more than 30 cm. tall, the stems erect; hoods rarely equal in length to anther head (36)
 36(35). Corolla reddish-purple or violet-color; hoods 1.5-2 mm. long, with very prominent marginal auricles somewhat longer than the broadly obtuse median lobe ...
 32. *A. brachystephana*.
 36. Corolla pale-green; hoods 4-5 mm. long, not as above . 14. *A. viridiflora*.
 37(34). Hoods obovate, without horns 33. *A. longifolia*.
 37. Hoods oblong to quadrate, with conspicuous acicular horns that more or less arch over the anther head (38)
 38(37). Corolla usually bright-crimson or scarlet, the lobes 5-10 mm. long
 34. *A. curassavica*.
 38. Corolla white to bright-pink, the lobes 3-5 mm. long (39)
 39(38). Inflorescences usually paired at the upper nodes, solitary below; flowers typically bright-pink 35. *A. incarnata*.
 39. Inflorescences solitary at the upper nodes; flowers white, the corolla occasionally tinged with purple on outer surface (40)
 40(39). Follicles erect on erect pedicels; seeds comose; distribution central and west Texas 18. *A. texana*.
 40. Follicles pendulous; seeds naked; distribution southeast Texas
 36. *A. perennis*.

1. *Asclepias Sperryi* Woods. Low suffruticose perennial; stems clustered from the rootstalk and branching repeatedly and rather fastigiately, very slender, 1-3 dm. tall, very minutely puberulent to essentially glabrous; leaves opposite, sessile, filiform, 6-8 cm. long, about 1 mm. wide, glabrous, revolute; inflorescences lateral at few of the uppermost nodes, sessile, 1- (or very rarely 2-) flowered; pedicels filiform, about 5 mm. long, glabrous; flowers rather small; calyx lobes ovate, about 2 mm. long; corolla rotate, pale-greenish-yellow, more or less tinged with purple without, the lobes about 5 mm. long; gynostegium sessile, pale-greenish-yellow or white, occasionally somewhat tinted with purple; hoods tubiform, about 4 mm. long, the base abruptly deflexed from the anther head, thence with ascending broadly expanded tips; crest wholly adnate, low; anther head very broadly cylindrical, about 1 mm. long and 2.5 mm. broad; follicles erect on deflexed pedicels, very narrowly fusiform, gradually attenuate, 5-7 cm. long, about 4 mm. thick, smooth, glabrous; seeds oval, about 5 mm. long, the white coma about 25 mm. long. Limestone ledges and slopes, open places among grass in the Trans-Pecos, Apr.-June; also n. Coah.

This is one of the oddest of American milkweeds, not only because of the peculiar floral structure but because of the extreme reduction of the inflorescence.

2. *Asclepias macrotis* Torr. Suffrutescens perennial; stems densely clustered from the rootstalk, repeatedly and rather fastigiately branching, very slender and twiggy (rather resembling an *Ephedra*), 1-3 dm. tall, very inconspicuously puberulent in decurrent lines

from the nodes, glabrate at maturity; leaves opposite, sessile, filiform to acicular, 3.5-8 cm. long, 1-4 mm. broad, revolute, glabrous; inflorescences solitary and lateral from the upper nodes, few- to several-flowered; peduncles slender, 2-10 mm. long; pedicels very slender, about 1 cm. long; flowers rather small; calyx lobes ovate, 2-3 mm. long; corolla pale-greenish-yellow, slightly tinged with purple without, the lobes about 5 mm. long; gynostegium subsessile, cream-color or yellowish; column about 0.5 mm. long and 2 mm. broad, ovate-lanceolate; hoods very narrowly acuminate, 4-6 mm. long; horn strongly adnate, much shorter than the hood, ascending, usually minutely pilosulose at the tip; anther head truncately conic, about 1 mm. long and 2 mm. broad; follicles erect on deflexed pedicels, very narrowly fusiform, long-apiculate, 4-7 cm. long, 5-7 mm. thick, smooth, inconspicuously pilosulose to glabrate; seeds oval, about 6 mm. long, the white or pale-tawny coma 25-35 mm. long. Dry hills and mesas in the Trans-Pecos, June-Sept.; from N.M. and adj. Colo. to Okla., Tex., Ariz. and Coah.

3. *Asclepias asperula* (Dcne.) Woods. Low herbaceous perennial from very stout rootstalks; stems usually clustered from the rootstalk, ascending or somewhat decumbent, simple, rather stout, 2-6 dm. tall, minutely and rather roughly pilosulose; leaves irregularly approximate, shortly petiolate, lanceolate to linear-lanceolate, narrowly acuminate at apex, acute to obtuse at base, 1-2 dm. long, 1-3 cm. broad, firmly membranaceous, usually more or less conduplicate, minutely and usually rather sparsely pilosulose; petioles 3-7 mm. long; inflorescences terminal and solitary, usually many-flowered and very crowded, sessile to long-pedunculate; peduncles obsolete to 1 dm. long, minutely and rather sparsely pilosulose, rather stout; pedicels more slender, 15-25 mm. long, minutely tomentulose; flowers rather large; calyx lobes ovate to ovate-lanceolate, 4-5 mm. long, minutely pilosulose or puberulent; corolla rotate, pale-yellowish-green, sometimes slightly flushed with purple without, the lobes 9-12 mm. long; gynostegium sessile; hoods broadly clavate-falciform, abruptly deflexed from the anther head, thence with ascending bluntish but tapering tips, 8-10 mm. long, greenish-cream to rather dark-purple; anther head very depressed, about 2 mm. long and 5 mm. broad; follicles erect on deflexed pedicels, rather narrowly fusiform, gradually attenuate, 4-13 cm. long, 1-2.5 cm. thick, smooth, minutely pilosulose; seeds oval, 7-8 mm. long, the pale-tawny coma about 3 cm. long.

The following two phases of this species are found in Texas.

1. Inflorescences usually obviously and rather long-pedunculate; hoods usually rather dark-purple; leaves usually linear-lanceolate subsp. *asperula*.
1. Inflorescences sessile or subsessile; hoods usually greenish-cream-color; leaves usually more broadly lanceolate subsp. *capricornu*.

Subsp. *asperula* occurs mostly in w. Tex. where it is found on flats, sandy and rocky hillsides, and in desert swales, mesquite, oak and juniper areas, Mar.-Nov.

Subsp. *capricornu* (Woods.) Woods. occurs mostly in cen. Tex. where it is found in prairies, plains, pastures, and on limestone or clay hills, Mar.-July. *Acerates decumbens* (Nutt.) Dcne., *Asclepiodora decumbens* (Nutt.) Gray, *Asclepias decumbens* (Nutt.) K. Schum., *A. capricornu* Woods., *A. asperula* var. *decumbens* (Nutt.) Shiners.

4. *Asclepias viridis* Walt. ANTELOPE-HORN. Low herbaceous perennial from a stout subfusiform rootstalk; stems erect, ascending or more or less decumbent, usually simple or branched from the caudex, rather stout, to 6 dm. tall, essentially glabrous; leaves irregularly approximate, shortly petiolate, ovate to oblong-lanceolate, shortly acute to obtuse at apex, acute to broadly rounded at base, 4-13 cm. long, 1-6 cm. broad, firmly membranaceous, yellowish-green, essentially glabrous; petioles 3-10 mm. long; inflorescences terminal and solitary or more usually also lateral at few to several of the uppermost nodes, several- to many-flowered, crowded, pedunculate; peduncles 3-6 cm. long, minutely and scatteringly puberulent; pedicels rather slender, 1-3 cm. long, very minutely and sparsely puberulent; flowers large and rather showy; calyx lobes lanceolate, 4-5 mm. long, essentially glabrous; corolla rotate, pale-green, the lobes 13-15 mm. long and usually with ascending tips; gynostegium sessile, pale-purplish-rose; hoods abruptly deflexed from the anther head and with rather shortly ascending rounded clavate tips, 4-6 mm. long; anther head broadly truncate-conic, about 2 mm. long and broad; follicles erect on deflexed pedicels, broadly fusiform to ovoid, greatly inflated, shortly apiculate, 6-13 cm. long, 2-3 cm. broad, minutely puberulent to glabrate; seeds oval, about 7 mm. long, the

white or pale-tawny coma about 4 cm. long. *Asclepiodora viridis* (Walt.) Gray. Glades, prairies, dry hillsides, and dry pine barrens in e. half of Tex., Mar.-Sept.; from Tenn. to Fla., w. to Neb. and Tex.

5. *Asclepias amplexicaulis* Sm. Herbaceous perennial; stems stout, simple, to 1 m. tall, glabrous; leaves opposite, sessile, broadly ovate or oval to oblong-lanceolate, broadly rounded to obtuse and frequently mucronate at apex, broadly cordate and amplexicaul at base, rather thickly membranaceous or subcoriaceous, more or less glaucous, usually crispate; inflorescences terminal and solitary, rarely lateral also from the uppermost node, usually many-flowered; peduncles stout, 1-3 dm. long, shorter when lateral; pedicels rather stout, 2-5 cm. long; flowers rather large; calyx lobes lanceolate, 3-5 mm. long, glabrous; corolla reflexed-rotate, greenish and more or less deeply suffused with purple or rose, the lobes 9-11 mm. long; gynostegium pale-purple or rose, rather shortly stipitate; column cylindrical, about 2 mm. long, 2.5-3 mm. broad; hoods tubular-cucullate, rather indistinctly dentate to essentially entire, about 5 mm. long; horn adnate below the middle, rather stoutly acicular, about half longer than the hood, broadly arching over the anther head; anther head broadly cylindrical, 3-3.5 mm. long, about 3 mm. broad; follicles erect on deflexed pedicels, rather narrowly falcate-fusiform, 10-16 cm. long, 1-2 cm. thick, smooth, glabrous and rather glaucous; seeds broadly oval, 6-9 mm. long, the pale-tawny coma 4-6 cm. long. Open woods, prairies, old dunes, spreading to clearings, meadows, pastures, roadsides and railways, chiefly in sandy or gravelly soil, in the e. third of Tex., s. to the Rio Grande Plains, Apr.-June; from N.H., s. to Fla., w. to Neb. and Tex.

6. *Asclepias elata* Benth. Herbaceous perennial; stems rather stout, simple, 3-7 dm. tall, glabrous, glaucous; leaves opposite, sessile, very broadly oval to oblong, very broadly obtuse to rounded at apex, broadly cordate at base, 7-14 cm. long, 2.5-7 cm. broad, glabrous, very glaucous; inflorescences terminal or subterminal and usually lateral from few of the uppermost nodes, several- to many-flowered, rather long-pedunculate; peduncles relatively stout, glabrous or very inconspicuously pilosulose in opposed lines; pedicels more slender, 1.5-3 cm. long, densely white-tomentulose; flowers rather large; calyx lobes ovate, 3-4 mm. long; corolla pale-green or greenish-white, the lobes 8-12 mm. long; gynostegium sessile, greenish-white to cream; hoods saccate at the base, compressed-rhomboid, 4-6 mm. long, truncate, somewhat deflexed from the anther head, the crest wholly adnate and about as long as the hood; anther head broadly truncate-conic, about 3 mm. long and 4 mm. broad; follicles erect on deflexed pedicels, fusiform, rather narrowly apiculate, 8-12 cm. long, 1-2.5 cm. thick, smooth, very inconspicuously pilosulose to glabrate; seeds oval, about 7 mm. long, the pale-tawny coma 25-45 mm. long. *A. glaucescens* H.B.K. Dry rocky slopes in open pine, juniper or oak woods in canyons in the Trans-Pecos, June-Sept.; from w. Tex. to Ariz., s. through Mex. to Guat.

7. *Asclepias oenotheroides* Cham. & Schlecht. **HIERBA DE ZIZOTES.** Low herbaceous perennial; stems clustered from the thick rootstalk, ascending or decumbent, moderately stout, more or less branched from the base or simple, to 45 cm. long, minutely puberulent; leaves opposite, rather long-petiolate, rhombic-ovate to oblong-lanceolate, obtuse to acute at apex, acute to broadly obtuse at base and abruptly cuneate to the petiole, 4-12 cm. long, 1-6 cm. broad, firmly membranaceous, pale-green, minutely puberulent particularly beneath; petioles 1-2 cm. long; inflorescences lateral and solitary from few to several of the upper nodes, very shortly pedunculate or sessile, several-flowered; peduncles 1-2 cm. long or nearly obsolete, minutely puberulent; pedicels rather slender, 15-25 mm. long, minutely puberulent; flowers mediocre; calyx lobes ovate-lanceolate, 3-4 mm. long, minutely puberulent; corolla reflexed-rotate, greenish-white or yellow, the lobes 8-14 mm. long; gynostegium very shortly stipitate, pale-greenish-cream; column broadly obconic, about 1.5 mm. long and 2.5 mm. broad; hoods narrowly obovate-flabellate, 7-10 mm. long, conspicuously narrowed to a narrowly laminate stipe from somewhat above the middle, the tip broadly laminate and minutely erose or repand; horn adnate to near the tip of the hood, the free portion falciform and incurved, usually accompanied by a smaller posterior appendage; anther head truncate-conic, about 3 mm. long and 4-5 mm. broad; follicles erect on deflexed pedicels, broadly fusiform or ovoid, shortly apiculate, 7-9 cm. long, 1.5-2 cm. broad, smooth, minutely pilosulose to glabrate; seeds oval, 6-8 mm. long, the pale-tawny coma 2-2.5 cm. long. *A. longicornu* Benth., *A. Lindheimeri* Engelm. & Gray. Rocky, chiefly clay soil in llanos, mesas and hills, in dunes, salt marshes, fields and

thickets, along roadsides in much of w. half of Tex., flowering throughout the year; also N.M., s. to C.A.

8. *Asclepias Emoryi* (Greene) Small. Low herbaceous perennial; stems usually clustered from the rootstalk, ascending or decumbent, rather slender, more or less branched from the base or simple, 1-2 dm. long, minutely puberulent; leaves opposite, rather long-petiolate, rhombic-ovate to narrowly oblong-lanceolate particularly above, obtuse to narrowly acute at apex, acute to obtuse at base and abruptly cuneate into the petiole, 4-8 cm. long, to 4 cm. broad, firmly membranaceous, pale-green, minutely puberulent particularly beneath; petioles 1-1.5 cm. long; inflorescences lateral and solitary from few to several of the upper nodes, shortly pedunculate to sessile; peduncles obsolete to 2 cm. long, densely puberulent; pedicels rather slender, 1-2 cm. long, minutely puberulent; flowers rather small; calyx lobes lanceolate, 3-4 mm. long, minutely puberulent; corolla reflexed-rotate, dingy-greenish-yellow, the lobes 6-7 mm. long; gynostegium very shortly stipitate or essentially sessile, pale-greenish-cream; column broadly obconic, about 1 mm. long and 1.5 mm. broad; hoods oblanceolate, about 5 mm. long, conspicuously narrowed to a narrowly laminate stipe from near the tip, the tip laminate and rather deeply emarginate; horn wholly adnate to the sinus and more or less linguiform, enclosing the hood from above (rarely ascending); anther head truncate-conic, about 1.5 mm. long and broad; follicles erect on deflexed pedicels, more narrowly fusiform, rather narrowly attenuate, 6-9 cm. long, 1-1.5 cm. broad, minutely puberulent to glabrate; seeds broadly oval, about 8 mm. long, the pale-tawny coma 25-35 mm. long. Sandy prairies and dry plains, spreading to roadsides and railways in w.-cen. and s. Tex., Mar.-Oct.; also n.e. Mex.

9. *Asclepias speciosa* Torr. SHOWY-MILKWEED. Herbaceous perennial; stems usually very stout, simple, 6-10 dm. tall, densely white-tomentose generally; leaves opposite, shortly petiolate, broadly ovate or oval to rather narrowly oblong or ovate-lanceolate, usually very broadly obtuse to rounded at apex, rather rarely acute, very broadly obtuse to rounded and sometimes broadly and shallowly cordate at base, 6-20 cm. long, 3-14 cm. broad, firmly membranaceous, very densely white-tomentose beneath, more or less glabrate above; petioles to 15 mm. long; inflorescences lateral and solitary at few to several of the upper nodes, several- to many-flowered, densely white-tomentose throughout; peduncles rather stout, to 1 dm. long; pedicels 2-3 cm. long; flowers very large and showy; calyx lobes lanceolate, 5-6 mm. long, very densely white-tomentose; corolla purplish-rose, the lobes 1-1.5 cm. long; gynostegium pale-rose or pinkish-cream, subsessile; column very broadly obconic, about 1 mm. long and 3 mm. broad; hoods very narrowly ovate-lanceolate, gradually attenuate at apex, widely spreading, 1-1.4 cm. long; horn adnate toward the base, falciform-acicular, sharply incurved, very much shorter than the hoods; anther head broadly truncate-conic, about 3 mm. long and 4.5 mm. broad; follicles erect on deflexed pedicels, broadly or rather narrowly fusiform, abruptly or gradually attenuate, 9-12 cm. long, 2-3 cm. broad, densely spiny to smooth, very densely white-tomentose; seeds oval, 6-9 mm. long, the white coma 3-4 cm. broad. Widely tolerant to habitat and becoming weedy in cult. fields, roadsides and railways on the High Plains in Tex., May-Sept.; from s. Man. to B.C., Minn. and Tex., w. to the Pac. Coast.

This species has the most massive flowers of any milkweed.

10. *Asclepias obovata* Ell. Herbaceous perennial from a rather deep slender rootstalk; stems rather stout, simple or branching infrequently, 1.5-5 dm. tall, softly tomentulose; leaves opposite, shortly petiolate, quite variable in size and outline, the lowermost usually broadly oval to oblong or quadrate, becoming narrower and smaller above, broadly acute to rounded at apex, obtuse to rounded or truncate at base, 3-8 cm. long, 1-4 cm. broad, firmly membranaceous, densely tomentulose particularly beneath; petioles to 1 cm. long; inflorescences terminal, solitary or also lateral from the uppermost few nodes, several- to rather many-flowered, subsessile to very shortly pedunculate, densely tomentulose; peduncles obsolete to about 5 mm. long; pedicels rather stout, 8-10 mm. long; flowers rather large; calyx lobes ovate-lanceolate, 4-5 mm. long, pilosulose; corolla reflexed-rotate, pale-greenish-yellow, the lobes 9-10 mm. long; gynostegium shortly stipitate, pale-greenish-orange; column obconic, about 1.5 mm. long and 2 mm. broad; hoods broadly oblong-oval, rounded and sometimes notched at apex, about 6 mm. long; horn basally adnate, rather narrowly falciform, sharply incurved, about as long as the hoods; anther head truncately conic, about 3 mm. long and 4 mm. broad; follicles erect on deflexed

pedicels, more or less tomentose, to 12 cm. or more long, fusiform. Sandy oak and pine woods, spreading to savannahs, fields and roadsides, in s.e. Tex., May-Sept.; from S.C. to Fla. and w. to Tex.

11. *Asclepias purpurascens* L. PURPLE-MILKWEED. Herbaceous perennial; stems rather stout, simple, 4-10 dm. tall, minutely pilosulose when young, becoming glabrate; leaves opposite, petiolate, broadly ovate or oval to ovate- or oblong-lanceolate, obtuse to acute at apex, obtuse to broadly rounded at base and very shortly and abruptly cuneate into the petiole, 6-18 cm. long, 3-10 cm. broad, firmly membranaceous, dark-green and glabrate above, paler and densely and generally puberulent below; petioles to 25 mm. long; inflorescences terminal and solitary or paired, several- to rather many-flowered; peduncles rather slender, 1.5-9 cm. long, minutely puberulent; pedicels slender, 2-3.5 cm. long, minutely puberulent; flowers rather large and very showy; calyx lobes ovate-lanceolate, 3-4 mm. long, minutely puberulent; corolla deep-rose, reflexed-rotate, the lobes 7-10 mm. long; gynostegium deep-rose, very shortly stipitate; column obconic, 1.5-2 mm. long, 2.5-3 mm. broad; hoods oblong-elliptic, acute to acuminate, 6-7 mm. long; horn about half-adnate, falciform and sharply incurved, much shorter than the hoods; anther head truncately conic, about 2 mm. long and 3 mm. broad; follicles erect on deflexed pedicels, narrowly fusiform, gradually attenuate, 10-16 cm. long, 1-2 cm. thick, smooth, minutely puberulent to glabrate; seeds oval, 5-6 mm. long, the white coma 35-45 mm. long. Thickets and open woods, prairies and fields, spreading to roadsides and railways, in n.e. Tex., Apr.-July; from s. Ont. and N.E., s. to Va. and Tex.

12. *Asclepias tuberosa* L. BUTTERFLY-WEED, ORANGE MILKWEED, CHIGGER-FLOWER. Herbaceous perennial from a deep woody rootstalk; stems rather stout and clustered from the crown, usually branching only at the inflorescence, to 9 dm. tall, conspicuously hirsutulous or hispid generally; leaves irregularly approximate, usually crowded, rather shortly petiolate, extremely variable, very narrowly lanceolate to very broadly oblanceolate, rounded to acuminate at apex, cuneate to broadly cordate at base, 3-11 cm. long, to 3 cm. broad, firmly membranaceous and occasionally irregularly crisped-revolute, more or less conspicuously hirsutulous particularly beneath; petioles 1-5 mm. long; inflorescence of 1 to several terminal and subterminal helicoid branches bearing few to numerous umbelliform cymes at the nodes of the more or less reduced and usually opposite leaves, the cymes several- to many-flowered; flowers moderately large; calyx lobes lance-trigonal, 2-3 mm. long, minutely hirsutulous; corolla reflexed-rotate, usually orange or occasionally reddish, yellow or red, the lobes 7-8 mm. long; gynostegium usually orange, rarely yellow; column narrowly obconic, about 2 mm. long and 1.5 mm. broad; hoods cucullate, lanceolate, 4-5 mm. long; horn basal, narrowly acicular, slightly longer than the hoods, gradually arching over the anther head; anther head cylindrical, about 2 mm. long and broad; follicles erect on deflexed pedicels, narrowly fusiform, 8-15 cm. long, 1-1.5 cm. broad, smooth, pilosulose; seeds broadly oval, 5-7 mm. long, the white coma 3-4 cm. long. A frequent and widespread species, in prairies, dry fields, thickets, open woods, canyons, and on dunes and hillsides throughout much of the state but especially in the e. two thirds, Apr.-Sept.; throughout most of e. half of U.S.

The following two phases of this species are found sympatrically in Texas.

1. Leaves typically deeply cordate at base subsp. *interior* Woods.
1. Leaves typically obtuse to truncate at base, varying to slightly cordate
..... subsp. *terminalis* Woods.

13. *Asclepias nummularia* Torr. YERBA DE CUERVO. Diminutive herbaceous perennial, more or less subscapose in appearance because of the decumbent habit and the long peduncles; stems usually several clustered from the rootstalk, decumbent to ascending, usually frequently branched, rarely simple, relatively slender and apparently more or less ancipitous or laterally compressed, 4-10 cm. long, finely tomentulose above to glabrate below; leaves opposite, subsessile or very shortly petiolate, in 2 to 3 closely approximate pairs, very broadly ovate or suborbicular to ovate-lanceolate, broadly rounded to acute at apex, broadly rounded and somewhat cordate to obtuse at base, 1.5-4 cm. long, 1-4 cm. broad, firmly membranaceous or somewhat subsucculent, more or less glaucous, finely subarachnoid-tomentulose particularly beneath, infrequently glabrate; inflorescences terminal and subterminal at the uppermost nodes, few- to several-flowered, long-peduncu-

late, minutely tomentulose; peduncles 2-6 cm. long, slender; pedicels very slender, 1.5-3 cm. long; flowers rather small; calyx lobes ovate, about 2 mm. long, purplish, finely pilosulose; corolla reflexed-rotate, purplish-rose, the lobes 3-5 mm. long; gynostegium pale-rose, shortly stipitate; column broadly obconic, about 0.5 mm. long and 2.5 mm. broad; hoods broadly obovate, broadly obtuse or rounded at the tip, about 3 mm. long; horn strongly adnate, very broadly falciform or reduced to a rather low crest about as long as the hood or somewhat shorter; anther head truncately conic, 2-2.5 mm. long, 3-3.5 mm. broad; follicles erect on deflexed pedicels, very broadly fusiform, shortly apiculate, 5-6 cm. long, 1.5-2 cm. broad, smooth, finely tomentulose to glabrate; seeds oval, about 6 mm. long, the pale-tawny coma about 25 mm. long. Rocky hillsides, arid grassland, dry ravines, in gravel or clay, in the Trans-Pecos, Mar.-June; from w. Tex., s. Ariz. and n. Mex.

14. *Asclepias viridiflora* Raf. Herbaceous perennial; stems usually rather stout, simple, rarely branching at the base, often zigzag above, to 9 dm. tall, inconspicuously puberulent to glabrate; leaves opposite to irregularly approximate, shortly petiolate to sessile, extremely variable, suborbicular to linear, 4-13 cm. long, 1-6 cm. broad, firmly membranaceous, inconspicuously puberulent to glabrate; petioles obsolete to 1 cm. long; inflorescences subterminal and solitary and usually lateral at few to many of the upper nodes, usually many-flowered, crowded and hemispherical, puberulent; peduncles obsolete to 15 mm. long, rather stout; pedicels more slender, 1-2 cm. long; flowers moderately large; calyx lobes ovate-lanceolate, 3-4 mm. long, minutely puberulent; corolla reflexed-rotate, pale-green, the lobes 6-7 mm. long; gynostegium sessile, pale-green; hoods deeply saccate, oblongish, 4-5 mm. long, nearly equaling the anther head; anther head 3-4 mm. long; follicles erect on deflexed pedicels, narrowly fusiform, long-attenuate, 7-15 cm. long, 1.5-2 cm. thick, finely puberulent to glabrate; seeds oval, 6-7 mm. long, the pale-tawny coma 3-5 cm. long. *Acerates viridiflora* (Raf.) Pursh. Glades, prairies, plains and rocky or sandy hillsides, spreading to old fields and roadsides, local and infrequent throughout most of Tex., Apr.-Aug.; from e. Can., s. to Ga., w. to Mont. and Ariz., also Coah.

Although the flowers are quite uniform in this species the leaves are tremendously variable.

15. *Asclepias scaposa* Vail. Small subscapose herbaceous perennial from a fleshy napiform rootstalk; stems simple or sparingly branched from the base, slender, to 2 dm. tall, minutely and generally puberulent or pilosulose; leaves opposite, petiolate, broadly oval to oblong-elliptic, obtuse to acute at apex, obtuse to rounded at base, 2-6 cm. long, to 25 mm. broad, membranaceous, generally pilosulose above and below; petioles to 4 cm. long; inflorescences terminal, solitary, several- to many-flowered; peduncle relatively stout, 7-17 cm. long; pedicels slender, 1-2 cm. long; flowers rather small; calyx lobes lance-trigonal, about 2 mm. long, minutely pilosulose; corolla reflexed-rotate, livid-rose or purplish, the lobes 4-5 mm. long; gynostegium shortly stipitate, cream-color flushed with purple or rose; column obconic, 1-1.5 mm. long and broad; hoods tubular-cucullate, erose-dentate, 2-3 mm. long; horn acicular and ascending, somewhat longer than the hood and strongly adnate to it, entire; anther head about 1.5 mm. long and 2 mm. broad; follicles erect on deflexed pedicels, narrowly fusiform, about 5 cm. long and 5-7 mm. thick, smooth, minutely pilosulose; seeds unknown. Dry, sunny, gravelly openings among scrub oaks, and on mt. sides and flats in s. Trans-Pecos, Mar.-May; from w. Tex. and s. N.M. to n.-cen. Mex.

16. *Asclepias arenaria* Torr. Herbaceous perennial; stems relatively stout, to 8 dm. tall or more, simple or branching infrequently, densely tomentulose; leaves opposite, petiolate, very broadly obovate-oval and more or less subquadrate, broadly rounded and more or less retuse at apex, truncate or broadly rounded and occasionally somewhat cordate at base, rather uniform in shape and size, 6-9 cm. long, 4-8 cm. broad, firmly membranaceous, concolorous, more or less generally white-tomentulose particularly beneath; petioles to 13 mm. long; inflorescences lateral and solitary at several to many of the upper nodes, rather many-flowered; peduncles obsolete to about 3 cm. long, densely tomentulose; pedicels rather stout, 1-2 cm. long, densely white-tomentulose; flowers rather large; calyx lobes ovate-lanceolate, 6-7 mm. long, densely and minutely white-tomentulose; corolla reflexed-rotate, pale-green, the lobes 9-10 mm. long; gynostegium shortly stipitate, white or cream; column obconic, about 2 mm. long and 3.5 mm.

broad; hoods more or less broadly 2-lobed at the tip, subquadrate; horn about half-adnate, rather narrowly falciform, sharply incurved, somewhat longer than the hood; anther head truncately conic, about 3 mm. long and 4 mm. broad; follicles erect on deflexed pedicels, rather broadly fusiform and shortly apiculate, 7-9 cm. long, 15-25 mm. broad, finely tomentulose to glabrate; seeds broadly oval, about 11 mm. long, the pale-tawny coma about 25 mm. long. Sandy soil, spreading to roadsides, mostly in the Plains Country of n. Tex., s. to Galveston and Brewster cos., June-Sept.; from S.D. to Tex., w. to Colo., N.M. and Chih.

The characteristic broad 4 lobes of the hoods apparently consist of two marginal auricles, with the median lobe broadly retuse, as in the leaves.

17. *Asclepias latifolia* (Torr.) Raf. Herbaceous perennial; stems stout, simple or infrequently branching, 2-6 dm. tall, minutely tomentulose when very young, soon becoming glabrate; leaves opposite, very shortly petiolate, very broadly oval-obovate to obovate-subquadrate, broadly rounded and frequently somewhat retuse at apex, very broadly rounded and frequently somewhat cordate at base, 4-16 cm. long, 4-13 cm. broad, firmly membranaceous and somewhat coriaceous, concolorous and somewhat glaucous, minutely white-tomentulose generally when very young, soon glabrate; petioles about 5 mm. long; inflorescences lateral at several to numerous of the upper nodes, sessile or very shortly pedunculate, many-flowered; peduncles obsolete to 15 mm. long; pedicels rather slender, 2.5-3 cm. long, minutely white-tomentulose; flowers rather large; calyx lobes ovate-lanceolate, about 4 mm. long; corolla reflexed-rotate, pale-green, sometimes tinted purplish without, the lobes 11-12 mm. long; gynostegium shortly stipitate, greenish-white; column broadly obconic, about 2 mm. long and 3 mm. broad; hoods subquadrate, truncate or broadly retuse, about 4 mm. long; horn wholly adnate, very broadly falciform, sharply incurved, somewhat longer than the hood; anther head about 3 mm. long and 4 mm. broad, truncately conic; follicles erect on deflexed pedicels, broadly fusiform, shortly apiculate, 6-8 cm. long, 1.5-3 cm. broad, smooth, essentially glabrous; seeds oval, about 7 mm. long, the pale-tawny coma about 2 cm. long. Mixed prairies, badlands and high plains, spreading to roadsides and railways in w. and n.w. Tex., May-Sept.; from s.w. Neb. and Tex., w. to s. Ut. and s.e. Calif.

18. *Asclepias texana* Heller. Herbaceous perennial, becoming somewhat shrubby at the base after several years; stems slender, to 5 dm. tall, usually branching, inconspicuously pilosulose in decurrent lines from the nodes; leaves opposite, petiolate, broadly oval to narrowly oblong-elliptic, obtuse to acuminate at apex, obtuse or rarely attenuate at the base, 2-7 cm. long, to 35 mm. broad, thinly membranaceous, finely puberulent upon the midrib and veins beneath; petioles to 1 cm. long, minutely pilosulose; inflorescences solitary at the uppermost nodes, several- to many-flowered; peduncles slender, 1-2 cm. long; pedicels 1-1.3 cm. long, finely puberulent; flowers small; calyx lobes narrowly lanceolate, 1.5-2 mm. long, minutely puberulent; corolla reflexed-rotate, white, the lobes about 3 mm. long and widely spreading; gynostegium long-stipitate, white; column cylindric, about 1.5 mm. long and 0.7 mm. wide at the base; hoods cucullate, about 2 mm. long, rounded at the tip; horn basal, narrowly acicular, nearly twice as long as the hood, slightly incurved over the anther head; anther head about 2.5 mm. long; follicles erect on erect pedicels, narrowly fusiform, 9-12 cm. long, smooth, glabrous; seeds broadly oval, about 8 mm. long, the white coma about 2 cm. long. Canyons, arroyos and rocky hills in the Edwards Plateau and Trans-Pecos, May-Aug.; also n. Mex.

19. *Asclepias variegata* L. WHITE-FLOWERED MILKWEED. Herbaceous perennial from a fleshy fusiform rootstalk; stems rather slender, simple, 3-12 dm. tall, inconspicuously pilosulose in decurrent lines from the nodes; leaves opposite, petiolate, broadly oval, broadly rounded and apiculate to obtuse or broadly acute at apex, very broadly obtuse or rounded at base, 8-15 cm. long, 4-9 cm. broad, dark-green and glabrous above, glaucous and very sparsely pilosulose beneath; petioles 1-2 cm. long; inflorescences usually solitary and terminal, occasionally also lateral from very few of the uppermost nodes, rather many-flowered and very compactly hemispherical; peduncles rather slender, 1-7 cm. long; pedicels 1-3 cm. long; flowers rather large and showy; calyx lobes ovate, about 3 mm. long; corolla rotate, white, the lobes 7-8 mm. long; gynostegium white except for the purple column, shortly stipitate; column obconic, about 1.5 mm. long and 2-2.5 mm. broad; hoods cucullate, conduplicate and inflated, very broadly obovate, about

2.5 mm. long; horn adnate toward the base, falciform and sharply inflexed, much shorter than the hood; anther head about 2 mm. long and 3 mm. broad; follicles erect on deflexed pedicels, narrowly fusiform, gradually apiculate, 10-15 cm. long, 1.5-2 cm. thick, glaucous, minutely pilosulose; seeds oval, about 5 mm. long, the white coma 25-45 mm. long. *Biventaria variegata* (L.) Small. Thickets and open woods, usually in sandy or rocky soil in e. Tex., Apr.-July; from Conn., s. to n. Fla., s. Mo. and Tex.

One of the most beautiful of all milkweeds.

20. *Asclepias tomentosa* Ell. Herbaceous perennial; stems rather stout, simple or branching infrequently, 2-7 dm. tall, softly and rather inconspicuously appressed-puberulent; leaves opposite, petiolate, variable in outline and size, typically oblong or oval to oblong-lanceolate or obovate, usually obtuse to acute or rounded and somewhat retuse at apex, broadly acute to rounded at base, 4-9 cm. long, 1.5-5 cm. broad, firmly membranaceous, dark-green above, pale beneath, softly and generally puberulent particularly below; petioles about 1 cm. long; inflorescences lateral and solitary at several or numerous of the upper nodes, sessile or subsessile, several- to many-flowered; pedicels 1.5-2 cm. long, softly puberulent; flowers rather large; calyx lobes lanceolate, 3-6 mm. long; corolla pale-yellowish-green, somewhat flushed with orange without, the lobes 9-10 mm. long; gynostegium yellowish-cream, very shortly stipitate; column obconic, about 1.5 mm. long and 3 mm. broad; hoods obovate-subquadrate, truncate, about 4 mm. long; horn wholly adnate, falciform, sharply incurved, longer than the hood; anther head truncately conic, 3.5-4 mm. long and 5-6 mm. broad; follicles erect on deflexed pedicels, narrowly fusiform, 10-12 cm. long, about 1 cm. broad, smooth, softly puberulent to glabrate; seeds broadly oval, about 1 cm. long, the pale-tawny coma about 45 mm. long. Sandy soil in fields and pine barrens, in s.e. Tex., May-July; from N.C., s. to Fla. and Tex.

21. *Asclepias prostrata* Blackwell. Herbaceous perennial from thick woody crowns; stems prostrate, simple or branched near base, 1-4 dm. long, 1-2 mm. thick, conspicuously pilosulose distally, eventually glabrate; leaves opposite, pseudodistichous by twisting of stems, triangular to deltoid-lanceolate, 15-35 mm. long, 5-20 mm. broad, very shallowly cordate (proximal leaves) or truncate at base, acute (or the most proximal leaves obtuse) at apex, marginally entire and on drying crispate, membranous, firm, minutely pilose on both surfaces, grayish-green, dull; petioles 1-3 mm. long; umbels axillary, mostly 5-flowered; peduncles 5-12 mm. long, pilosulose; pedicels 1-2 cm. long, pilosulose; calyx lobes lanceolate, 4-5 mm. long, dorsally minutely pilosulose; corolla reflexed-rotate, greenish-white to rose-color; corolla lobes 12-15 mm. long, narrowly obovate or broadly oblanceolate; gynostegium long-stipitate, cream-colored suffused with rose-color; column conic, about 3.5 mm. long and 2 mm. broad; hoods obovate and slightly flabellate, 7-8 mm. long, narrowed below (above the midpoint) to a spongy-solid and somewhat laminate stipe, basally with laminate auricles; horn compressed-clavate, with an acicular horn inflexed over the anther head, slightly shorter than the hood and wholly adnate to it; anther head cylindrical, 4 mm. long and 4.5 mm. broad; follicles erect on deflexed pedicels, obliquely ellipsoid, about 55 mm. long and 2 cm. thick, verrucose and pubescent; seeds broadly oval, 7-8 mm. long, the white coma to 2 cm. long. In red sandy loam in the Rio Grande Plains in s. Tex., June-Aug.; also Tam.

22. *Asclepias rubra* L. Herbaceous perennial; stems rather slender, 4-10 dm. tall, simple, glabrous or very inconspicuously pilosulose in decurrent lines from the nodes; leaves opposite, sessile or subsessile, broadly ovate to narrowly lanceolate, acute to acuminate at apex, rounded to somewhat cordate at base, 5-16 cm. long, to 65 mm. broad, firmly membranaceous, glabrous, dark-green above, glaucous beneath; inflorescences terminal and lateral from the uppermost nodes, commonly paired when terminal, several- to many-flowered; peduncles 3-10 cm. long; pedicels 1-1.5 cm. long; flowers moderately large; calyx-lobes lance-trigonal, about 3 mm. long, glabrous; corolla reflexed-rotate, dull-red to purplish or lavender, the lobes 8-9 mm. long; gynostegium stipitate, usually pinkish-cream or purplish; column cylindrical, about 2 mm. long and broad; hoods lanceolate, acute, 6-7 mm. long; horn basal, narrowly acicular, somewhat shorter than the hoods, gradually arching over the anther head; anther head narrowly conic, about 3 mm. long and broad, with entire or very inconspicuously notched wings; follicles erect on deflexed pedicels, rather narrowly fusiform, 8-12 cm. long and 15 mm. thick, smooth, glabrous; seeds broadly oval, about 7 mm. long, the white coma about 4 cm. long. Bogs,

marshes, wet meadows and low pine barrens in e. Tex., May-Aug.; from N.J., s. to Ga., Ala., La. and Tex.

23. *Asclepias lanceolata* Walt. Herbaceous perennial from rather tuberous rootstalks; stems relatively slender, simple, 5-12 dm. tall, glabrous or essentially so; leaves opposite, linear-lanceolate, narrowly acuminate at apex, acute to obtuse at the base, 7-25 cm. long, to 17 mm. broad, firmly membranaceous, glabrous, somewhat glaucous beneath; inflorescences terminal, solitary or paired, few-flowered; peduncles 15-75 mm. long; pedicels 1-2 cm. long; flowers moderately large; calyx lobes lance-trigonal, 2.5-4 mm. long; corolla reflexed-rotate, dull-red, the lobes 9-10 mm. long; gynostegium stipitate, yellow, orange or reddish; column cylindrical, about 2 mm. long and 1.5 mm. broad; hoods broadly oblong, rounded at the tip, 5-6 mm. long; horn basal, narrowly acicular, somewhat shorter than the hood, arching over the anther head; anther head narrowly conic, about 3 mm. long and 2.5 mm. broad, the wings conspicuously spurred at the base; follicles erect on deflexed pedicels, narrowly fusiform, 8-10 cm. long, about 1 cm. thick, smooth, glabrous; seeds broadly oval, about 1 cm. long, the coma about 35 mm. long. Incl. var. *paupercula* (Michx.) Fern. Brackish to fresh marshes, wet pine barrens and low glades in s.e. Tex., May-Aug.; from s. N.J., s. to Fla. and w. to Tex.

24. *Asclepias quinqueidentata* Gray. Herbaceous perennial from rather deep tuberous rootstalks; stems relatively slender, simple above, branching rather cespitosely below, the basal branches usually dwarf and sterile, 1.5-3 dm. tall, minutely and generally puberulent, rarely glabrate; leaves opposite, sessile or subsessile, linear to filiform, 4-9 cm. long, 1-2 mm. broad, minutely and scatteringly pilosulose or puberulent; inflorescences subterminal from several of the uppermost nodes, few-flowered; peduncles rather slender, 1-8 cm. long; pedicels slender, 1.5-2 cm. long; flowers rather small; calyx lobes lance-trigonal, about 2 mm. long, minutely pilosulose to glabrate; corolla reflexed-rotate, pale-green, usually flushed with rose or purple without, the lobes 5-6 mm. long; gynostegium shortly stipitate, greenish-white; column narrowly obconic, about 1 mm. long and 1.5 mm. broad; hoods cylindrical-cucullate, sharply erose, about 3 mm. long; horns completely adnate to the hoods and about half longer than they, ascending and scarcely arching; anther head cylindrical, about 2 mm. long and broad; follicles erect on deflexed pedicels, narrowly fusiform, 7-10 cm. long, 5-8 mm. thick, smooth, minutely puberulent; seeds oval, 5-7 mm. long, the pale-tawny coma 3-4 cm. long. Rocky hills and arroyos in w. Tex., June-Aug.; from w. Tex. to s. Ariz. and n. Mex.

25. *Asclepias stenophylla* Gray. Herbaceous perennial from subnapiform tuberous rootstalks; stems rather slender, simple, to 8 dm. tall, very minutely puberulent to glabrate; leaves irregularly approximate, sessile, linear, 6-14 cm. long, 2-4 mm. broad, rather strictly ascending, firmly membranaceous, very minutely and scatteringly puberulent to glabrate; inflorescences lateral at few to several of the uppermost nodes, several-flowered, subsessile to very shortly pedunculate; peduncles obsolete to 1 cm. long, minutely puberulent; pedicels very slender, 5-8 mm. long, minutely puberulent; flowers rather small; calyx lobes lanceolate, 2-3 mm. long, minutely puberulent; corolla rotate, pale-greenish-white or yellow, the lobes about 6 mm. long; gynostegium sessile, pale-greenish cream-color or white; hoods saccate and strongly adnate to the column, conspicuously excurrent-auriculate at the base, oblong-elliptic, 3-4 mm. long, the tip deeply 2-lobed; horn or crest wholly adnate to form a third lower median lobe; anther head broadly truncate-conic, about 2 mm. long and broad; follicles erect on erect pedicels, very narrowly fusiform and gradually attenuate, 9-12 cm. long, about 7-8 mm. thick, minutely pilosulose to glabrate; seeds oval, 5-6 mm. long, the pale-tawny coma 3-3.5 cm. long. *Acerates angustifolia* (Nutt.) Dcne. Prairies and limestone glades, mainly in n.e. Tex., s. to Harris Co., June-Aug.; from s.w. Mo., w. to S.D., e. Colo. and Tex.

26. *Asclepias Engelmanniana* Woods. Herbaceous perennial; stems rather stout, simple or branching infrequently from the caudex, 6-12 dm. tall, glabrous or essentially so; leaves irregularly approximate, sessile, linear, 12-18 cm. long, 1.5-3 mm. broad, rather laxly spreading or reflexed, more or less canaliculate, firmly membranaceous or somewhat subsucculent, glabrous; inflorescences lateral from several to many of the upper nodes, many-flowered and very crowded, subsessile to shortly pedunculate; peduncles obsolete to about 2 cm. long, relatively stout, very inconspicuously appressed-puberulent; pedicels rather slender, about 1 cm. long, inconspicuously appressed-puberulent; flowers rather small; calyx lobes ovate-lanceolate, about 3 mm. long, essentially glabrous; corolla

reflexed-rotate, pale-green and more or less flushed with purple without, the lobes about 5 mm. long; gynostegium sessile; hoods deeply saccate and excurrently auriculate at the base, broadly truncate or broadly retuse at the tip, about 3 mm. long, without a horn; anther head depressed-spheric, about 2.5 mm. long and 3 mm. broad; follicles erect on deflexed pedicels, narrowly fusiform, gradually attenuate, 8-12 cm. long, about 15 mm. thick; seeds oval, about 7 mm. long, the pale-tawny coma about 3 cm. long. *Acerates auriculata* Engelm., *Asclepias auriculata* (Engelm.) Holz., not H.B.K. Prairies and swales, open sandy hillsides, draws, washes and bottoms in w. two thirds of Tex., e. to Hays Co., May-Sept.; from Neb., s. to Tex., Coah. and Ariz.

27. *Asclepias linearis* Scheele. Herbaceous perennial from rather short and superficial rootstalks; stems slender, 2-5 dm. tall, usually branching only at the base, inconspicuously pilosulose in decurrent lines from the nodes; leaves opposite, sessile or subsessile, linear, 3-9 cm. long, 1-4 mm. broad, membranaceous, glabrous or minutely puberulent along the midrib beneath; inflorescences solitary at several or many of the upper nodes, several-flowered; peduncles slender, 1-1.5 cm. long; pedicels 5-7 mm. long; flowers small; calyx lobes lance-trigonal, about 2 mm. long, minutely puberulent; corolla reflexed-rotate, greenish-white, the lobes 3-4 mm. long; gynostegium long-stipitate, white; column cylindrical, about 1 mm. long and 0.5 mm. broad; hoods cucullate, subquadrate, about 1.5 mm. long; horn basal, narrowly acicular, somewhat longer than the hood, gradually arching over the anther head; anther head about 1.5 mm. long and slightly narrower; follicles erect on erect pedicels, narrowly fusiform, 5-10 cm. long, smooth, glabrous; seeds broadly oval, about 5 mm. long, the white coma about 2 cm. long. *A. verticillata* var. *linearis* (Scheele) Pollard. Dry prairies in s. Tex., May-Nov.; endemic.

28. *Asclepias pumila* (Gray) Vail. Herbaceous perennial from rather deep rootstalks; stems cespitose from the crown, simple or branching infrequently below ground level, relatively slender, to 3 dm. tall, minutely puberulent generally; leaves spirally approximate and very crowded or the lowest occasionally verticillate, sessile, filiform and strictly ascending, 2-4 cm. long and about 1 mm. broad, usually strongly revolute, glabrous or essentially so; inflorescences subterminal, corymbosely clustered at the uppermost nodes, several-flowered; peduncles 1-1.5 cm. long; pedicels slender, about 1 cm. long; flowers small; calyx lobes lance-trigonal, about 1 mm. long, scatteringly pilosulose to nearly glabrous; corolla reflexed-rotate, white or faintly suffused with rose or yellowish-green, the lobes 2-3 mm. long; gynostegium narrowly stipitate, greenish-white; column cylindrical, about 1 mm. long and broad; hoods cucullate, broadly oval, about 1.5 mm. long; horn basal, narrowly acicular, almost twice longer than the hood and gradually arching over the anther head; anther head cylindrical, about 1.25 mm. long and 1 mm. broad; follicles erect on erect pedicels, narrowly fusiform, 4-8 cm. long, about 6 mm. broad; seeds broadly oval, 4-6 mm. long, the white coma about 25 mm. long. In sandy soil, mesquite prairies and limestone buttes in the High Plains of n.w. Tex., June-Sept.; from N.D., s. to Tex. and N.M., w. to Wyo.

This plant is known to be poisonous to livestock.

29. *Asclepias subverticillata* (Gray) Vail. Herbaceous perennial from rather stout woody rootstalks; stems to 12 dm. tall, almost invariably with sterile dwarf microphyllous branches, occasionally simple, more or less puberulent in decurrent lines from the nodes, occasionally quite glabrous; leaves predominantly 3 to 5 in whorls but occasionally opposite above on the flowering stems, shortly petiolate, linear, 2-13 cm. long, 1-4 mm. broad, membranaceous, glabrous to inconspicuously pilosulose, those of the sterile dwarf branches opposite and much-reduced and giving the plant a heterophyllous aspect; petioles 1-2 mm. long; inflorescences usually solitary at the upper nodes, rarely paired, several- to many-flowered; peduncle slender, 1.5-3 cm. long; pedicels slender, 5-8 mm. long; flowers relatively small; calyx lobes narrowly trigonal, 1.5-2 mm. long, inconspicuously pilosulose to glabrate; corolla reflexed-rotate, white, rarely slightly suffused with greenish-purple, the lobes 3-5 mm. long; gynostegium narrowly stipitate, white; column cylindrical, about 1 mm. long and slightly narrower; hoods cucullate, oval, about 1.5 mm. long; horn basal, narrowly acicular, somewhat longer than the hoods, gradually arching over the anther head; anther head cylindrical, about 1.5 mm. long and broad; follicles erect on erect pedicels, narrowly fusiform, 5-9 cm. long and 6-8 mm. thick, smooth, glabrous or inconspicuously pilosulose; seeds broadly oval, 7-8 mm. long, the white coma about 2 cm. long. *A. galioides* of Am. auth. Sandy and rocky plains and flats

in the w. half of Tex., especially in the Trans-Pecos, May-Sept.; from Tex., w. to Ut., Colo., Ariz. and n. Mex.

This plant is known to be very poisonous to livestock.

30. *Asclepias verticillata* L. Herbaceous perennial from rather short superficial root-stalks; stems slender, to 9 dm. tall, simple or rarely with short sterile branches, more or less puberulent in decurrent lines from the nodes, rarely glabrate; leaves chiefly 3 or 4 in whorls, rarely opposite in part, sessile or subsessile, linear, 1.5-7 cm. long, about 1.5 mm. broad, membranaceous, glabrous or essentially so, usually somewhat revolute; inflorescences solitary or paired at the upper nodes, few- to many-flowered; peduncles slender, 1.5-3 cm. long; pedicels slender, 6-8 mm. long; flowers small; calyx lobes narrowly trigonal, 1.5-2.5 mm. long, sparsely pilosulose to glabrous; corolla reflexed-rotate, greenish-white, occasionally somewhat flushed with purple without, the lobes about 3.5 mm. long; gynostegium narrowly stipitate, greenish-white; column narrowly cylindrical, about 1 mm. long and somewhat narrower; hoods cucullate, subquadrate, about 1.5 mm. long; horn basal, narrowly acicular, about twice as long as the hood and arching gradually over the anther head; anther head cylindrical, about 2 mm. long and somewhat narrower; follicles erect on erect pedicels, narrowly fusiform, 7-10 cm. long and 5-8 mm. thick, smooth, glabrous; seeds oval, about 5 mm. long, the white coma about 25 mm. long. Prairies, thickets, and open woods, usually in rather dry soil, also in dunes and spreading to roadsides and fence corners, in e. half of Tex., Apr.-Aug.; from e. Can., s. to Fla. and w. to N.D. and Tex.

31. *Asclepias involucrata* Torr. Low herbaceous perennial from woody subfusiform rootstalks; stems clustered from the rootstalk, ascending or more or less decumbent, rather slender, branching repeatedly, to 25 cm. long, minutely and generally puberulent; leaves irregularly approximate, sessile or subsessile, narrowly lanceolate, very narrowly acuminate at apex, acute to obtuse at base, to 12 cm. long and 1 cm. broad, firmly membranaceous and somewhat conduplicate, inconspicuously pilosulose particularly beneath; inflorescences terminal and usually also from the few uppermost nodes, sessile, several- to few-flowered; pedicels 15-25 mm. long, minutely puberulent; flowers rather small; calyx lobes ovate-lanceolate, 3-4 mm. long; corolla reflexed-rotate, pale-whitish-green or pink, tinged purple without, the lobes 5-7 mm. long; gynostegium shortly stipitate, white with purplish keels; column obconic, 1-1.5 mm. long and 1.5-2.5 mm. broad; hoods ovate, acute, 3-4 mm. long; horns adnate toward the base, falciform, incurved or ascending, about as long as the hood; anther head truncate-conic, about 2 mm. long and 3 mm. broad; follicles erect on deflexed pedicels, stoutly fusiform, shortly apiculate, 4-7 cm. long, 1.5-2 cm. broad, very inconspicuously pilosulose to glabrate; seeds oval, 6-8 mm. long, the pale-tawny coma 2-3 cm. long. Dry gravelly hills, prairie flats and arroyos in the High Plains, Apr.-May; from Tex. to Ariz. and adj. Ut., Colo. and Kan., also n. Mex.

32. *Asclepias brachystephana* Torr. Herbaceous perennial; stems clustered from the rootstalk, rather slender, branching repeatedly toward the base, 1-4 dm. tall, minutely tomentulose when young, soon becoming glabrate; leaves opposite, shortly petiolate, lanceolate to linear-lanceolate, narrowly acuminate at apex, acute to rounded at base, 6-12 cm. long, to 12 mm. broad, firmly membranaceous, more or less conduplicate, minutely white-tomentulous when young, soon becoming glabrate; petioles 3-10 mm. long; inflorescences lateral and solitary at the upper nodes, shortly pedunculate, several- to many-flowered; peduncles rather slender, to 3 cm. long, conspicuously white-tomentulose; pedicels very slender, 1-2 cm. long, conspicuously white-tomentulose; flowers rather small; calyx lobes ovate, about 2 mm. long, minutely puberulent; corolla reflexed-rotate, reddish-purple or violet, the lobes 5-6 mm. long; gynostegium sessile or subsessile, pale-rose or cream; hoods saccate, 1.5-2 mm. long, with very prominent marginal auricles somewhat longer than the broadly obtuse median lobe; horn adnate about midway, linguiform, somewhat longer than the hood; anther head truncately conic, about 2 mm. long and 3 mm. broad; follicles erect on deflexed pedicels, broadly fusiform, rather gradually apiculate, 6-9 cm. long, 1-2 cm. thick, minutely puberulent to glabrate, longitudinally striate; seeds oval, about 7 mm. long, the pale-tawny coma 2-3 cm. long. Sandy and rocky plains, dry flats, gullies and stream banks, spreading to fields and roadsides, often eaten by livestock on overgrazed range, in w. Edwards Plateau and Trans-Pecos, May-Sept.; from w. Tex. to Ariz., s. to cen. Mex.

33. *Asclepias longifolia* Michx. Herbaceous perennial from a stout rather tuberous rootstalk; stems rather slender, simple, 2-7 dm. tall, minutely pilosulose; leaves irregularly approximate, sessile or subsessile, linear-lanceolate, gradually acuminate at apex, attenuate at base, 6-18 cm. long, 2-10 mm. broad, minutely pilosulose to glabrate; inflorescences terminal and solitary and lateral from few of the uppermost nodes, several- to many-flowered, rather lax and hemispherical, pedunculate; peduncles slender, 2-6 cm. long, rarely obsolete, minutely pilosulose; pedicels very slender, 1.5-2 cm. long, minutely pilosulose; corolla reflexed-rotate, pale-greenish-white, liberally tinted with purple (particularly without), the lobes about 5 mm. long; gynostegium shortly but definitely stipitate, greenish-white tinted with purple below; column about 1.5 mm. long and 1 mm. broad; hoods deeply saccate, obovoid, about 2 mm. long, without a horn, much lower than the anther head; anther head about 1.5 mm. long and broad; follicles erect on deflexed pedicels, narrowly fusiform, long-attenuate, minutely pilosulose, 8-12 cm. long, about 1 cm. thick; seeds rather broadly oval, about 1 cm. long, the white coma about 35 mm. long. Flatwoods, swamps, savannahs and low pinelands in e. Tex., Apr.-July; from Del. to Fla. and w. to Tex.

34. *Asclepias curassavica* L. VEINTTUNILLA. Herbaceous annual; stems 3-12 dm. tall, frequently rather woody toward the base, simple or branched, minutely arachnid-tomentulose when young, soon glabrate; leaves opposite, petiolate, elliptic-lanceolate, acute to acuminate at apex, acute to obtuse at base, 5-12 cm. long, 1-3 cm. broad, minutely pilosulose when very young, soon glabrate, thinly membranaceous; petioles to 1 cm. long; inflorescences solitary at the upper nodes, several- to many-flowered; peduncles 3-6 cm. long; pedicels 1-2 cm. long; flowers rather large and showy; calyx lobes narrowly lanceolate, 2-3 mm. long; corolla reflexed-rotate, bright-crimson, rarely yellow or white, the lobes 5-10 mm. long; gynostegium long-stipitate, deep-yellow; column cylindric or conic, 2-3 mm. long and 1 mm. broad at the base; hoods cucullate, distinctly stipitate, broadly oblong, rounded at the tip, 3-5 mm. long; horn basal, narrowly acicular, 4-5 mm. long, slightly incurved over the anther head; anther head cylindrical, 2-3 mm. long, 1.5-2.5 mm. broad; follicles erect on erect pedicels, narrowly fusiform, 6-10 cm. long, smooth, glabrous; seeds broadly oval, 5-7 mm. long, the white coma 2-3 cm. long. In moist or wet soil in s. Tex., Apr.-Aug.; an almost ubiquitous waif of the trop. and subtrop. of Am., also widely introd. in the trop. of the Old World.

35. *Asclepias incarnata* L. SWAMP-MILKWEED. Herbaceous perennial from rather short and superficial rootstalks; stems usually fairly stout, 4-15 dm. tall, simple to copiously branched; leaves opposite or very rarely certain nodes condensed to form a false whorl, petiolate, ovate-elliptic to linear-lanceolate, acute to acuminate at apex, obtuse to somewhat cordate at base, 5-15 cm. long, to 4 cm. broad, membranaceous; petioles to 1 cm. long; inflorescences usually paired at the upper nodes, solitary below, several- to many-flowered; peduncles 1.5-7 cm. long; pedicels 1-1.5 cm. long; flowers rather small; calyx lobes linear-oblong, 1-1.5 mm. long, pilosulose; corolla bright-pink or rarely white, reflexed-rotate, the lobes 3-4 mm. long; gynostegium paler pink or rarely white; column cylindric, 1-1.5 mm. long, about 1 mm. wide; hoods cucullate, rounded at the tip, about 1.5 mm. long; internal horn narrowly acicular, slightly incurved over the stigma head, somewhat longer than the hood; anther head about 1.5 mm. long; follicles erect on erect pedicels, fusiform, long-attenuate, 7-9 cm. long, to 12 mm. thick, smooth, glabrous to generally pilosulose; seeds broadly oval, 7-10 mm. long, the white coma about 2 cm. long. In moist or wet soil about water-bodies and in marshes from the Plains Country to s.-cen. Tex., June-Oct.; from e. Can., s. to Fla. and w. to Ut. and N.M.

The following two phases of this species are found sympatrically in Texas.

1. Plant scatteringly and inconspicuously pubescent to essentially glabrous; stems usually repeatedly branching; leaves usually rather narrowly oblong- to linear-lanceolate, the apex gradually acuminate, the base obtuse to truncate, rather long-petiolate var. *incarnata*
(var. *longifolia* Gray).
1. Plant generally and conspicuously pubescent; stems simple or branching infrequently; leaves ovate- to broadly oblong-elliptic, the apex acute to abruptly acuminate, the base rounded to somewhat cordate, infrequently broadly obtuse, rather short-petiolate var. *pulchra* (Ehrh.) Fern.

36. *Asclepias perennis* Walt. Herbaceous perennial from rather short and superficial rootstalks; stems slender, 3-5 dm. tall, usually branching only from the base, very inconspicuously pilosulose in decurrent lines from the nodes or essentially glabrous; leaves opposite, elliptic-lanceolate to narrowly oblong or broadly oval to ovate-elliptic, acuminate at apex, attenuate at the base, 5-14 cm. long, to 15 mm. broad, thinly membranaceous, glabrous; petioles to 15 mm. long; inflorescences solitary at the uppermost nodes, several- to many-flowered; peduncles slender, 1-4 cm. long; pedicels 1-1.3 cm. long, usually somewhat suffused with purple; flowers small; calyx lobes oblong-elliptic, about 1 mm. long, sparsely and minutely pilosulose; corolla reflexed-rotate, white and usually suffused with pale-pink, the lobes 3-4 mm. long; gynostegium stipitate, white; column cylindric, about 1 mm. long and wide; hoods cucullate, rounded at the tip, about 2 mm. long, slightly longer than the anther head; horn basal, narrow-acicular, somewhat longer than the hoods, slightly arching over the anther head; follicles pendulous on deflexed peduncles, rather broadly ovoid-fusiform with a rather long apical beak, 4-7 cm. long, 1-2.5 cm. broad, smooth, glabrous; seeds broadly oval, about 15 mm. long, without a coma. Low swampy ground, frequently with bald cypress, alluvial woods, sloughs and ditches mostly in s.e. Tex., Apr.-Aug.; from S.C., s. to Fla. and w. to Tex., s. Mo., Ill. and s.w. Ind.

2. CYNANCHUM L.

Small to large twining vines, with anther, fruit and seed characters similar to those in *Asclepias*; leaves opposite; inflorescences axillary, abbreviated, few- to many-flowered; corolla funnelform to campanulate, white to yellowish or yellow-green, small; appendages of crown thin and flat, in one row.

About 150 species mostly in the warmer regions of both hemispheres.

1. Leaf blades 1 cm. or more wide, with cordate base (2)
1. Leaf blades less than 1 cm. wide, with narrowed to rounded-truncate base (3)
- 2(1). Peduncle mostly shorter than petiole of subtending leaf; appendages nearly as long as the corolla, deeply divided into linear segments (resembling staminodes) 1. *C. laeve*.
2. Peduncle about as long as or longer than petiole of subtending leaf; appendages less than two thirds as long as the corolla, broadly oblong with toothed or lobed summit 2. *C. unifarium*.
- 3(1). Flowers rather numerous, terminating naked peduncles longer than the pedicels; corolla lobes glabrous within; leaf blades narrowly linear to linear-lanceolate, the larger ones 4-9 cm. long 3. *C. angustifolium*.
3. Flowers solitary or few, peduncles very short or absent; corolla lobes pilose or pubescent within; leaf blades lanceolate to oblong-elliptic, 1-4 cm. long (4)
- 4(3). Corolla lobes minutely puberulent within; appendages narrowly lanceolate to ovate and acuminate, slightly longer than the stamen column 4. *C. Maccartii*.
4. Corolla lobes conspicuously pilose within; appendages linear-lanceolate to linear-filiform, 1.5 to 2 times as long as the stamen column (5)
- 5(4). Corolla 3.6-5.2 mm. long 5. *C. barbigerum* var. *barbigerum*.
5. Corolla 2.8-3.2 mm. long 5. *C. barbigerum* var. *breviflorum*.

1. *Cynanchum laeve* (Michx.) Pers. BLUE-VINE, SAND-VINE. Twining vine to 3 m. long or more, glabrescent or somewhat puberulent; leaves with a petiole to 45 mm. long, triangular-lanceolate to deltoid, to 8 cm. long and 5 cm. wide, deeply cordate with the rounded basal lobes separated by a wide sinus, acute to shortly acuminate at apex; flowers white, sweet-scented, in peduncled umbelliform clusters or abbreviated racemes in axils of the leaves; peduncle mostly shorter than petiole of subtending leaf; sepals ovate-elliptic, with scarious margins, puberulent, about 2 mm. long; corolla about 6 mm.

long; appendages nearly or about as long as the corolla, deeply divided into linear segments; follicles slender, lanceolate in outline, smooth, somewhat angled, to 15 cm. long and 3 cm. thick. *Enslentia albida* Nutt., *Ampelamus albidus* (Nutt.) Britt. In silty clay or sand in low moist woods or fields, often weedy and climbing on shrubs or fences, from n.-cen. to the coast in s.-cen. Tex., Aug.-Sept.; from Pa. to Ind., Mo. and Kan., s. to Ga. and Tex.

2. *Cynanchum unifarium* (Scheele) Woods. TALAYOTE. Twining vine to 3 m. or more long, glabrescent or sparsely puberulent; leaves with petioles to 5 cm. long, broadly ovate to ovate-lanceolate or triangular-lanceolate, to 9 cm. long and 7 cm. wide, deeply cordate with the rounded basal lobes separated by a wide sinus, abruptly acute to long-acuminate at apex; flowers cream-color or greenish-white, in racemes in the axils of the leaves; peduncle usually about as long as or longer than petiole of subtending leaf; sepals elliptic-lanceolate, acute, about 2.5 mm. long and 1 mm. wide, puberulent; petals fleshy, somewhat dilated on each side near the strongly recurved apex, obtuse, about 3.5 mm. long and 1.3 mm. wide; appendages oblong-quadrate, usually 3-lobulate at apex; follicle lanceolate in outline, smooth, to 1 dm. long and 25 mm. thick. *Rouliniella unifaria* (Scheele) Vail, *Cynanchum Palmeri* (Wats.) Blake, *C. Watsonianum* Woods. In scrub forests and thickets, climbing over trees and shrubs, mainly on the Edwards Plateau and in the Rio Grande Plains and Trans-Pecos, May-Oct.; also n.e. Mex.

3. *Cynanchum angustifolium* Pers. Vine slender, glabrous, somewhat succulent, twining, to 1 m. or more long; leaves short-petioled, narrowly linear, acute, to 8 cm. long and 5 mm. wide; peduncles slender, mostly shorter than the leaves; cymes several-flowered; calyx 2-2.5 mm. long, the lobes ovate-lanceolate to lanceolate and acute; corolla purplish or greenish-white, 6-8 mm. broad, the lobes ovate and acuminate; crown lobes 1.5-2 mm. long, retuse; follicles slender, to 7 cm. long and 5 mm. thick. *Lyonia palustris* (Pursh) Small, *Seutera palustris* (Pursh) Vail, *Cynanchum palustre* (Pursh) Heller. Climbing over shrubs and herbs in and on the edge of salt marshes and in moist sandy soils, local along the Gulf Coast, May-Aug.; from N.C. to Fla. and Tex.; also Bah. I. and W.I.

4. *Cynanchum Maccartii* Shinnars. Twining glabrous much-branched vine; leaves shortly petiolate, linear to linear-lanceolate, acute to acuminate at apex, cuneate or sometimes rounded at base, dark-green above, pale-green beneath, to 5 cm. long and 1 cm. wide, usually less than 3 cm. long and 5 mm. wide; corymbs nearly sessile, to 10-flowered; pedicels 3 mm. long or less; calyx lobes less than 1 mm. long, acutish; corolla fleshy-thickened, greenish-white or cream-colored, about 2 mm. long, open-campanulate; corolla lobes linear-oblong, acutish, strongly recurved, densely puberulent on inner surface; appendages narrowly lanceolate to ovate-lanceolate, longer than the stamen column; follicles slender, smooth, to about 4 cm. long. *Metastelma Palmeri* Wats., non *C. Palmeri* (Wats.) Blake. On rocky bluffs and in pasturelands in the Rio Grande Plains and on the Edwards Plateau, May-Oct.; also n.e. Mex.

5. *Cynanchum barbigerum* (Scheele) Shinnars. Glabrous or sparsely puberulent intricately twining vine; stems wiry, much-branched; leaves with slender petioles to 8 mm. long, subcoriaceous, linear to linear-oblong or elliptic-lanceolate, obtuse-apiculate to acute or acuminate at apex, broadly rounded at base, in drying with somewhat revolute margins, to 5 cm. long and 12 mm. wide, usually much smaller; corymbs subsessile or on a peduncle to 1 cm. long, as many as 5-flowered; pedicel 3-4 mm. long, subtended by a minute bract; calyx lobes ovate, about 1 mm. long, glabrous; corolla fleshy-thickened, white or creamy-white, open-campanulate, 2.8-5.2 mm. long, lobed to near base; corolla lobes linear to linear-lanceolate, strongly recurved above middle, glabrous on outer surface, densely long-pilose on inner surface; appendages linear-lanceolate to linear-filiform, as much as twice as long as stamen column; follicle smooth, narrowly lanceolate in outline, long-attenuate, to 5 cm. long. *Metastelma barbigerum* Scheele. Trailing over boulders and climbing on herbs and shrubs in open woodlands and on open slopes on the Edwards Plateau and in the Rio Grande Valley, w. to the Trans-Pecos, Mar.-July; also n.e. Mex.

The var. *breviflorum* Shinnars differs from var. *barbigerum* solely in its smaller flowers, as shown in the key.

3. SARCOSTEMMA R. BR.¹⁵²

Suffrutescent dextrorsely twining or trailing vines, the stem simple to much-branched; leaves usually laminate, sometimes reduced to scales, usually with one or more glands on the ventral surface of the midrib at the base; stipules minute; inflorescences extra-axillary, umbelliform (in ours), terminating a naked peduncle; calyx 5-lobed nearly to the base, adnate to the corolla; usually with 1 to many alternate or indefinitely distributed squamellae within; corolla 5-lobed, rotate-subcampanulate; stamens 5, the filaments coherent to form a column, usually produced at their insertion upon the corolla to form a patelliform crown-ring often completely adnate to the corolla or to the filaments directly below the anthers, each filament bearing an inflated vesicular segment (crown-vesicle) directly below the anther; anthers 2-celled, the membranous dorsal appendage ovate to deltoid; follicle fusiform to obclavate; seeds unequally biconvex or flattened, with a micropylar coma.

A world-wide genus of about 10 species.

1. Stems rather densely puberulent with curved-appressed hairs; leaves typically with crisped margins, often purple-tinged; sepals narrowly lanceolate, usually more than 3 times as long as wide 1. *S. crispum*.
1. Stems glabrescent to densely pilose; leaves with entire margins, green; sepals ovate to lanceolate, usually less than 3 times as long as wide (2)
- 2(1). Stems usually densely pilose with spreading hairs; sepals 4-6 mm. long, pubescent on both surfaces 2. *S. Torreyi*.
2. Stems glabrescent or only sparsely puberulent with curved-appressed hairs; sepals 2-3 mm. long, pubescent on back only (3)
- 3(2). Leaf blades broadly to narrowly ovate-lanceolate to triangular-lanceolate, cordate at base, mostly less than 3 times as long as wide ... 3. *S. cyanchooides* var. *cyanchooides*.
3. Leaf blades linear-lanceolate to linear, hastate to rounded-cuneate at base, usually much more than 3 times as long as wide 3. *S. cyanchooides* var. *Hartwegii*.

1. *Sarcostemma crispum* Benth. Stems twining or trailing, green or gray, rather densely puberulent with curved-appressed hairs, simple or sparsely branched; leaves with petioles to 8 mm. long, narrowly lanceolate to linear, acuminate at apex, cordate to hastate or truncate at base, usually strikingly undulate-crispate or rarely not crispate, to 1 dm. long and 3 cm. wide, subcoriaceous, puberulent; inflorescences umbelliform, as many as 7-flowered; peduncle to 3 cm. long, shorter than the subtending leaves; bracts linear, minute; pedicels to 2 cm. long; calyx lobes narrowly lanceolate, 3-6 mm. long, copiously puberulent on both surfaces; squamellae solitary or rarely paired; corolla rotate-subcampanulate, greenish-purple without, purple within, the tube 1 mm. long; corolla lobes ovate-elliptic, obtuse, to about 1 cm. long, puberulent without, glabrous within, irregularly short-ciliate; ring of the crown thin, revolute, scarcely adnate to the column; follicles narrowly fusiform, long-attenuate, to 12 cm. long and 2 cm. thick, puberulent, finely striate. *Philibertella crispa* (Benth.) Vail, *Funastrum crispum* (Benth.) Schltr. In rocky soils on hills and on open-wooded slopes, often trailing over shrubs, in cen. and w. Tex., May-Aug.; from Colo. through Tex., N.M. and s. Ariz. to cen. Mex.

2. *Sarcostemma Torreyi* (Gray) Woods. Stems twining or trailing, gray or green, densely pilose with spreading hairs, sparsely branched; leaves with petioles to 15 mm. long, triangular-lanceolate, acute to acuminate at apex, cordate at base with the lobes descending, to 4 cm. long and 25 mm. wide below middle, subcoriaceous, densely pilose on both surfaces, with one or more glands on the midrib at the base; inflorescences umbelliform, as many as 10-flowered; peduncle to 35 mm. long, pilose; bracts linear, 1-2 mm. long; pedicels to 16 mm. long, pilose; calyx lobes ovate-lanceolate, 4-6 mm. long, puberulent on both surfaces; squamellae solitary or rarely paired; corolla rotate-subcampanulate, cream-colored with a purple spot at the base and a median purple spot on each lobe; corolla lobes ovate, acute, to about 1 cm. long, minutely puberulent without,

¹⁵² Adapted partly from R. W. Holm in Ann. Missouri Bot. Gard. 37:447-560. 1950.

glabrate within, fimbriate-ciliate; ring of the crown fleshy, adnate to the base of the crown-vesicles that are 2.5 mm. long; follicles fusiform, long-attenuate, about 8 cm. long and 12 mm. thick, pilose, finely striate. *Philibertella Torreyi* (Gray) Vail, *Funastrum Torreyi* (Gray) Schltr. On dry hillsides and scrubby woodland associations in the Chisos Mts. of the Trans-Pecos, May-Aug.; also in n. Mex.

3. *Sarcostemma cynanchoides* Dcne. Stems twining or trailing to 1 m. or more long, much-branched, glabrous to sparsely puberulent; leaves with petioles to 2 cm. long, broadly to narrowly ovate-lanceolate to triangular-lanceolate or linear to linear-lanceolate, acute to acuminate at apex, cordate to hastate or rounded-cuneate at base, to 6 cm. long and 35 mm. wide; thin-membranaceous, sparsely puberulent on both surfaces, with one or more glands on the midrib at the base; inflorescences umbelliform, as many as 20-flowered; peduncle slender, to 55 mm. long; bracts linear, minute; pedicels slender, to 17 mm. long; calyx lobes ovate to ovate-linear, 2-3 mm. long, pilosulose without, glabrous within; squamellae absent to solitary or paired; corolla rotate-subcampanulate, greenish-white to purple or pinkish, the tube 1-2 mm. long; corolla lobes ovate, acute to acuminate, 5-7 mm. long, glabrous within, fimbriate-ciliate; ring of the crown thin, revolute, not adnate to the base of the crown-vesicles that are 1.5 mm. long; follicles fusiform, to 7 cm. long, lanceolate in outline, attenuate above, puberulent. In sandy or rocky soils, usually climbing on shrubs, in the w. half of Tex., Apr.-Aug.; from Okla. and Tex., w. to Ut. and Calif., s. to cen. Mex.

Var. *cynanchoides* [*Funastrum cynanchoides* (Dcne.) Schltr., *Philibertella cynanchoides* (Dcne.) Vail] is widespread in the western half of Texas and it typically has broadly triangular-lanceolate leaves, whereas var. *Hartwegii* (Vail) Shinnars (*S. heterophyllum* of auth.), with linear to linear-lanceolate leaves, occurs only in the Trans-Pecos. Few specimens have been seen that are intermediate between these two varieties. The flowers of var. *cynanchoides* are also usually greenish-white while those of var. *Hartwegii* are usually purplish or pinkish.

4. MATELEA AUBL.

Herbaceous perennials or shrubby plants with slender simple or branched usually twining stems; leaves opposite, cordate, petiolate; flowers 5-merous, few to many in pairs or in pedunculate to sessile umbellate clusters that arise between the petioles; calyx commonly somewhat glandular within; corolla greenish to dark-purple, sometimes noticeably reticulate-veined, rotate to campanulate, sometimes spreading-reflexed, the lobes convolute in bud; crown typically small, annular or cupuliform, in the throat of the corolla; anthers partly hidden under the flattened stigma, openly transverse; follicle turgid, smooth or mostly muricate with soft warty processes, sometimes angular; seed with a coma.

A genus of about 130 species that are native to warm temperate and tropical regions of the Western Hemisphere.

1. Stems prostrate to suberect, not at all twining (2)
1. Stems twining, at least toward tips (5)
- 2(1). Peduncles absent (pedicels attached directly in leaf axils); stamen column with a single lobed fleshy disk around base (3)
2. Peduncles well-developed; stamen column surrounded by a double row of thin appendages (4)
- 3(2). Pedicels shorter than or equaling the adjacent petioles; corolla usually densely pubescent on inner surface1. *M. biflora*.
3. Pedicels (except lowest) exceeding the adjacent petioles; corolla glabrous on inner surface2. *M. cynanchoides*.
- 4(2). Outer appendages wider than long, slightly shorter to slightly longer than the stamen column, truncate to shallowly 3-lobed at summit3. *M. brevicoronata*.
4. Outer appendages longer than wide, slightly to much longer than the stamen column, prominently 2-pronged or 2-pointed at summit or rarely some of them single-pointed4. *M. parviflora*.

- 5(1). Flowers at middle and upper leaf axils on peduncles shorter than the pedicels or without peduncles; plants small, semitrailing or low-climbing (6)
- 5. Flowers all on elongate peduncles; medium to large climbing vines (10)
- 6(5). Corolla 3-4 mm. long 5. *M. parvifolia*.
- 6. Corolla 6-13 mm. long (7)
- 7(6). Peduncles present except in uppermost leaf axils, 1- to 5-flowered; corolla broadly campanulate or tubular on lower half (8)
- 7. Peduncles absent or essentially so; flowers solitary or paired, short-pedicelled; corolla rotate, not tubular (9)
- 8(7). Corolla more than 7 mm. long, the lobes glabrous on inner surface; crown usually shorter than stamen column, shallowly 5-lobed at most 8. *M. producta*.
- 8. Corolla 6-7 mm. long, the lobes densely pubescent on inner surface; crown at least twice as long as stamen column, deeply 5-lobed 9. *M. texensis*.
- 9(7). Crown (appendage around stamen column) saucer-shaped, fleshy-thickened, entire to shallowly 5-lobed 6. *M. sagittifolia*.
- 9. Crown deeply 5-parted, the thin oblong-quadrate appendages about 2 mm. long 7. *M. radiata*.
- 10(5). Corolla with tubular lower half 8. *M. producta*.
- 10. Corolla with a campanulate base or completely rotate (11)
- 11(10). Corolla lobes oblong-lanceolate to linear, not reticulate-veined (12)
- 11. Corolla lobes ovate to oval, conspicuously reticulate-veined on at least part of upper surface (13)
- 12(11). Peduncle and pedicels subequal in length; sepals glabrous or very sparsely ciliate at apex; plants not glandular 10. *M. gonocarpa*.
- 12. Peduncle much longer than the pedicels; sepals both hispid and short-pubescent; plants glandular 11. *M. decipiens*.
- 13(11). Plant invested by both long spreading hairs and short glandular-puberulence; peduncle longer than the subtending petiole; corolla glabrous on inner surface 12. *M. reticulata*.
- 13. Plant sparsely invested only with short curved hairs; peduncle shorter than the subtending petiole; corolla densely puberulent on inner surface 13. *M. edwardsensis*.

1. *Matelea biflora* (Raf.) Woods. Plant spreading-pilose and glanduliferous throughout; stems several from a thickened rootstock, simple or sparsely branched; leaves with petioles to 25 mm. long, suborbicular-ovate to broadly triangular-ovate, subtruncate to deeply cordate at base, broadly obtuse to acute at apex, to 5 cm. long and 3 cm. wide; flowers borne in pairs in axil of leaf, without a peduncle; pedicel to 1 cm. long; calyx lobes ovate, about 3 mm. long; corolla rotate, reddish-purple to dark-brown, about 13 mm. in diameter, lobed to near base; corolla lobes elliptic-oblong, obtuse, densely white-pubescent on the inner surface; stamen column with a single lobed fleshy disk around base; follicle muricate, ellipsoid, to 1 dm. long and 25 mm. thick. *Vincetoxicum biflorum* (Raf.) Heller. In clayey, rocky or sandy soils in grasslands and open woodlands in n.-cen. Tex., s. to e. Edwards Plateau and n.w. to the South Plains, Mar.-June; also Okla.

2. *Matelea cynanchoides* (Engelm.) Woods. Plant spreading-pilose and more or less glanduliferous throughout, malodorous; stems several from a thickened rootstock, simple or sparsely branched, ascending or spreading; leaves subsessile or with a petiole to 1 cm. long, suborbicular-ovate to broadly ovate-lanceolate, shallowly to deeply cordate at base, rounded to acute at apex, to 45 mm. long and 4 cm. wide; flowers borne in pairs in axil of leaf, without a peduncle; pedicel to 1 cm. long; calyx lobes ovate to elliptic, about 3 mm. long; corolla rotate, brownish to dark-maroon, 8-12 mm. in diameter, lobed to near base; corolla lobes ovate to ovate-elliptic, obtuse, marginate, pubescent to glabrescent on dull outer surface, glabrous and vernicose-appearing on inner surface; stamen column with a single lobed fleshy disk around base; follicle ellipsoid, more or less muricate, to 8 cm.

long and 25 mm. thick. *Vincetoxicum cynanchoides* (Engelm.) Heller. In sandy soil mostly in open woodlands in n.e. Tex., s. to the Gulf Coast and w. to the South Plains, Apr.-Aug.; also Okla.

3. *Matelea brevicoronata* (Robins.) Woods. Plant shaggy white-pubescent throughout with spreading or crinkly hairs; stems several from a slender-thickened rootstock, simple or very sparsely branched, spreading-prostrate; leaves subsessile or with petioles to 1 cm. long, suborbicular-ovate to ovate-lanceolate, truncate to broadly rounded or rarely shallowly cordate at base, acute to shortly acuminate at apex, to 4 cm. long and 3 cm. wide; peduncle slender, to 8 cm. long, supporting one or more clusters of small greenish flowers; pedicel less than 5 mm. long, subtended by a linear bract about 2 mm. long; calyx lobes linear-oblong, obtuse, about 2.5 mm. long; corolla rotate, lobed to near base; corolla lobes distinctly marginate, pubescent over the entire surface or sometimes glabrous, ovate-elliptic, obtuse, mostly wide-spreading, 3-4 mm. long, 1.5-2 mm. wide; outer appendages about as long as the stamen column; follicles ovoid-ellipsoid, to 7 cm. long and 3 cm. thick. *Gonolobus parviflorus* var. *brevicoronatus* Robins., *Vincetoxicum brevicoronatum* (Robins.) Vail. In sandy or gravelly soils in fields and open woodlands in the lower Rio Grande Plains, Mar.-Oct.; apparently endemic.

This species is represented by two distinct variants. Plants found in red sands in Webb County differ from those found elsewhere in having smaller, less pubescent, leaves, and corollas that are completely glabrous on the inner surface. With further study it may become necessary to segregate this plant as a separate entity.

4. *Matelea parviflora* (Torr.) Woods. Plant more or less white-pilose throughout with spreading hairs, malodorous; stems several from a thickened rootstock, simple or sparsely branched, prostrate-spreading; leaves with a petiole to 15 mm. long, suborbicular-ovate to broadly ovate-lanceolate, broadly rounded to truncate or shallowly cordate at base, broadly obtuse to acute at apex, to 55 mm. long and about as broad; peduncle slender, to 7 cm. long, supporting an interrupted raceme or several scattered clusters of small greenish flowers; pedicels to 5 mm. long; calyx lobes linear-oblong to elliptic-lanceolate, obtuse, 2-3 mm. long; corolla lobed to near base; corolla lobes ovate to linear-oblong or elliptic, obtuse, strongly reflexed, distinctly marginate, puberulent only at very base on inner surface, 3-5 mm. long; outer appendages exceeding the stamen column; follicles ellipsoid, puberulent, more or less muricate, to 9 cm. long and 2 cm. thick. *Vincetoxicum parviflorum* (Torr.) Heller. In sandy soil in prairies, mesquite plains and in open woodlands in the Rio Grande Plains, Mar.-Aug.; apparently endemic.

5. *Matelea parvifolia* (Torr.) Woods. Viny shrub with twining stems to 4 dm. long or more, more or less puberulent throughout with minute recurved hairs; leaves with slender petioles to 15 mm. long, deep-green, subcoriaceous, triangular-ovate to narrowly triangular-lanceolate, truncate to cordate or hastate at base, obtuse to acute at apex, to 23 mm. long and 18 mm. wide near base; flowers solitary or sometimes 2 in the leaf axils, short-pedicelled; calyx lobes about 1.5 mm. long; corolla reddish-black to dark-purple, deeply lobed, rotate; corolla lobes ovate, obtuse, spreading, 3-4 mm. long, white-puberulent below middle on inner surface; the fleshy 5 lobes of crown ovate, shorter than the stamen column; follicles puberulent, smooth to sparsely muricate, lanceolate in outline, attenuate, 5-7 cm. long. *Gonolobus parvifolius* Torr. On rocky ledges and slopes in the Trans-Pecos, Jan.-Apr.; from w. Tex. to Calif. and n. Mex.

6. *Matelea sagittifolia* (Gray) Woods. Viny shrub with twining stems to 3 dm. long or more, subglabrous to somewhat sparsely puberulent throughout with minute recurved-appressed hairs; leaves with petioles to 5 mm. long, subcoriaceous, narrowly to broadly triangular-lanceolate, cordate-sagittate at base, acute at apex, to 18 mm. long and 6 mm. wide across base; flowers one or two in the leaf axils, short-pedicelled; calyx lobes linear to linear-lanceolate, obtuse, 2.5-3 mm. long; corolla greenish, deeply lobed to near base; corolla lobes scarcely spreading, linear to linear-spatulate, obtuse to rounded at apex, 7-10 mm. long, 1.5-1.8 mm. wide; crown saucer-shaped, entire to very shallowly and inconspicuously 5-lobed; follicles not seen. *M. Woodsonii* Shinnery, *Gonolobus sagittifolius* Gray. In sandy and rocky areas in grasslands and open woodlands, rare in the Rio Grande Plains, Edwards Plateau and Trans-Pecos, Mar.-May; endemic.

7. *Matelea radiata* Correll. Slender twining vine; stem puberulent with appressed hairs; leaves opposite, with a slender puberulent petiole 5 mm. long or less, narrowly triangular-

lanceolate, thickish, shallowly sagittate to subcordate at the base, acute at apex, to 22 mm. long and 7 mm. wide at base, sparsely puberulent to essentially glabrous, the margins somewhat revolute; flower solitary in leaf axils, commonly with a second flower aborted in bud, on a much-abbreviated combined peduncle-pedicel that is shorter than the subtending petiole; sepals triangular-lanceolate, acute at apex, very sparsely puberulent on the outer surface, about 2.5 mm. long; corolla rotate; apparently reddish-brown, glabrous; corolla lobes united near base, spreading-radiate, linear-oblong, obtuse at apex, about 7 mm. long (to base) and 2 mm. wide; appendages of crown about 2 mm. long, oblong-quadrate, broadly concave-emarginate at the truncate apex, with a flangelike keel arising at the base on the ventral surface and often extended to well above the middle; fruit unknown. Known only from the Rio Grande Plains, June-July; endemic.

8. *Matelea producta* (Torr.) Woods. Intricately twining vine, malodorous, usually more or less pubescent or puberulent and somewhat glandular throughout; stems several from a thickened rootstock, mostly simple; leaves with petioles to 35 mm. long, triangular-ovate to triangular-lanceolate, deeply cordate at base to form a broad sinus, rather abruptly contracted above into an acuminate-attenuate apex, pubescent to subglabrous, to 9 cm. long and 5 cm. wide; peduncle axillary, usually shorter than the petiole of subtending leaf, rarely to 5 cm. long, supporting as many as 5 clustered flowers; calyx lobes ovate-elliptic to lanceolate, subobtuse to acute, pubescent, to about 6 mm. long; corolla greenish or brownish, to 13 mm. long, pubescent on outer surface, 5-lobed to about the middle; corolla lobes oblong-elliptic, obtuse, about 2.5 mm. wide; crown saucer-shaped, about equal to or shorter than the stamen column, subentire to very shallowly 5-lobed, the lobes with blunt ligules on their inner surface; follicles ellipsoid, smooth, glabrous, to 1 dm. long and 2 cm. thick. In rocky open soil, usually twining on other plants, in the Trans-Pecos, May-Sept.; from w. Tex. to s. Ariz. and n. Mex.

9. *Matelea texensis* Correll. Intricately twining vine, densely short-pubescent and more or less glandular throughout; stems several from a slender-thickened rootstock, simple, to at least 5 dm. long; leaves with petioles to 15 mm. long, broadly ovate to triangular-lanceolate, deeply cordate at base, abruptly contracted above into an acuminate-attenuate apex, to 45 mm. long and 25 mm. wide; flowers several, clustered on an axillary peduncle that is about as long as the pedicels; calyx lobes linear-lanceolate, acute, 2-3 mm. long; corolla campanulate, 6-7 mm. long, deeply 5-lobed to below the middle; corolla lobes linear-oblong to linear-lanceolate, obtuse to subacute, strongly recurved, about 1.5 mm. wide, densely hairy on their inner surface; crown about 2 mm. high, twice as long as the stamen column, deeply lobed into 5 rounded appendages, the appendages with a linear deflexed ligule on their inner surface; follicles unknown. Rare in the Trans-Pecos, in igneous soils, June-Aug.; endemic.

10. *Matelea gonocarpa* (Walt.) Shinnery. Stems pubescent with spreading hairs, wiry, twining; leaves with slender spreading-pubescent petioles that exceed the axillary inflorescences, usually ovate-elliptic to oblong-quadrate, to 15 cm. long and 1 dm. wide, pale on lower surface, cordate at base with the sinus usually narrow, abruptly acute to short-acuminate at apex; flowers numerous in an umbelliform cluster on a peduncle about as long as the pedicels, in bud conical and somewhat twisted; calyx lobes glabrous or only ciliate at apex, lanceolate, 3-4 mm. long; corolla brownish-purple to greenish-purple, lobed to near base; corolla lobes spreading, linear-lanceolate, obtuse to subacute, glabrous, to 14 mm. long; crown nearly rotate, much shorter than the stamen column, coarsely toothed around the margin; follicles glabrous, sharply angled, to 12 cm. long. *Vincetoxicum gonocarpum* Walt., *Gonolobus gonocarpos* (Walt.) Perry. High-climbing on trees and shrubs mostly along wooded streams and in thickets in e. half of Tex., May-July; from s.e. Va. to s. Mo., s. to Fla. and Tex.

11. *Matelea decipiens* (Alex.) Woods. Plant more or less pubescent with spreading hairs and glandular-puberulence throughout; stems stout, twining; leaves with stout petioles that are subequal to the axillary inflorescences, broadly ovate to subrotund, cordate at base with a narrow rounded sinus, abruptly acute to short-acuminate at the apex, to 15 cm. long and wide; flowers numerous in short-branched umbelliform clusters on a peduncle that is much longer than the pedicels; calyx lobes ovate-lanceolate to lanceolate, about 3 mm. long, pubescent throughout; corolla brownish-purple, lobed to near base, in bud conical; corolla lobes linear-oblong to linear-lanceolate, sometimes

widest above middle, to 15 mm. long, glabrous to puberulent on inner surface; crown thin-textured, more or less marginally erose-toothed, about as long as the stamen column; follicle angular. *Gonolobus decipiens* (Alex.) Perry. In sandy soils in open woodlands in e. Tex., Apr.-June; from S.C. to La., Tex., Okla. and Mo.

12. *Matelea reticulata* (Gray) Woods. Twining vine; stems slender, wiry, adorned with long spreading hairs and a short glandular-puberulence; leaves opposite, with a stoutish spreading-pubescent and glandular petiole to 55 (usually about 30) mm. long, orbicular-ovate to ovate, deeply cordate at base with the lobes often incurved, acute to short-acuminate at apex, to 11 cm. long and 8 cm. wide; peduncle usually about as long as or exceeding the subtending petiole, spreading-pubescent and glandular, supporting a few-flowered umbelliform inflorescence; calyx lobes ovate-lanceolate, acuminate, 3-4 mm. long, long-pubescent; corolla rotate, greenish, reticulate-veined throughout, glabrous on inner surface, lobed to well below the middle, 1-1.5 cm. across; corolla lobes rhombic-ovate to broadly obovate, rounded at apex; stamen column about 1.5 mm. long, the crown shallow; follicle sparingly muricate, lanceolate in outline, to 15 cm. long, brownish. *Vincetoxicum reticulatum* (Gray) Heller. In sandy or rocky soil in open woodlands, along fencerows and in thickets, climbing on other plants, in cen., s. and w. Tex., Apr.-Oct.; also n.e. Mex.

13. *Matelea edwardsensis* Cortell. PLATEAU MILKVINE. Twining vine; stem slender, sparsely short-pubescent with curved or appressed hairs; leaves opposite, sparsely short-pubescent; petioles slender, to 6 cm. long; blade thin, ovate, deeply cordate at the base with the lobes incurved and the sinus truncate to subtruncate at its base across the petiole, acute to abruptly short-acuminate at apex, to 75 mm. long and 7 cm. wide, dark-green on upper surface, pale-green on lower surface; peduncle axillary, much-abbreviated, to 12 mm. long, greatly exceeded by the subtending petiole, short-pubescent, supporting about 6 flowers in an umbelliform inflorescence; pedicels slender, to 1 cm. long; sepals triangular-lanceolate, acuminate, short-pubescent, about 3 mm. long; corolla broadly campanulate, lobed to below the middle; corolla lobes oval, rounded at apex, greenish, with parallel dark green veins below the middle and with reticulate veins above and along the margins to the sinuses, sparsely short-pubescent on outer surface, densely white-puberulent on inner surface, about 8 mm. long (to base) and 4 mm. wide; crown with 5 short distinct rounded spreading appendages, each appendage with a central ventral keel; follicle spiny, lanceolate in outline, long-attenuate at apex, about 1 dm. long. In stony or gravelly soils in open woodlands, climbing on trees and shrubs on the Edwards Plateau, Apr.-May; endemic.

5. PERIPLOCA L. SILK-VINE

About 10 species of the Mediterranean region, Africa and Asia.

1. *Periploca graeca* L. Plant twining; stems to 5 m. long; leaves opposite, petiolate, ovate-lanceolate to oblong, to 1 dm. long; flowers purple-brown, in long-peduncled terminal cymes, 2-2.5 cm. wide; corolla rotate, deeply lobed, the narrowly oblong corolla lobes densely villous on the upper side; crown rotate, adnate to base of corolla, its margin prolonged into 5 short rounded lobes opposite the petals and 5 long ascending linear appendages alternate with the petals; stamens villous on back; follicles linear-cylindric, divaricate. A nat. of Eur.; cult. and escaped in our region.

FAM. 152. CONVOLVULACEAE JUSS.¹⁵³

MORNING GLORY FAMILY

Annual or perennial herbs, vines or shrubs (trees south of our area); leaves alternate, simple or compound, entire, toothed or lobed (wanting in *Cuscuta*), without stipules; flowers axillary or terminal, solitary or cymose, perfect, 5-merous; sepals 5, equal or unequal (often overlapping laterally), separate or united in basal portion; corolla gamopetalous, regular (rarely with curved tube or slightly irregular limb), 5-angled to

¹⁵³ Contributed by Lloyd H. Shinnery; excluding *Cuscuta*.

deeply 5-lobed; stamens epipetalous; ovary 2- (occasionally 1- or 3- to 5-) celled, free from the calyx; fruit a 1- to several-seeded capsule (indehiscent in some species).

About 1,600 species in about 30 to 50 genera, in tropical (chiefly) and temperate regions of both hemispheres.

1. Leafless parasitic annual twiners, not ground-rooting by flowering time 11. *Cuscuta*, p. 1255.
1. Leafy or leafy-bracted ground-rooting annual or perennial twiners, trailers, erect herbs or shrubs (2)
 - 2(1). Stigmas linear or oblong, more than twice as long as broad (3)
 2. Stigmas globose to reniform or flat-topped, as broad as long or broader (minute and scarcely larger than style in some species) (5)
 - 3(2). Corolla nearly rotate when fully expanded, 5-18 mm. across 4. *Evolvulus*, p. 1244.
 3. Corolla funnelform to campanulate, 16-80 mm. across (4)
 - 4(3). Calyx not enclosed by large bracts; stigmas linear, flattened 7. *Convolvulus*, p. 1246.
 4. Calyx enclosed by 2 large bracts; stigmas oblong, slightly or not flattened 8. *Calystegia*, p. 1246.
 - 5(2). Corolla shorter than or up to twice as long as calyx, with prominent lobes one third to three fourths its total length, the lobes as long as wide or longer (6)
 5. Corolla more than twice as long as the calyx, shallowly lobed (lobes broader than long) or merely angled (8)
 - 6(5). Leaf blades orbicular-ovate to orbicular-reniform, cordate, becoming long-petioled 1. *Dichondra*, p. 1242.
 6. Leaf blades elliptic to oblong-lanceolate or reduced to small bracts, very short-petioled or sessile (7)
 - 7(6). Corolla yellow-green, shorter than calyx, its lobes about as long as wide; stems trailing, sometimes rooting at lower nodes 2. *Petrogenia*, p. 1243.
 7. Corolla white, nearly twice as long as calyx, its lobes much longer than wide; stems erect or with decumbent base 3. *Cressa*, p. 1243.
 - 8(5). Style usually 2-branched (rarely 1 branch suppressed); stigmas minute, little larger than diameter of style (9)
 8. Style unbranched; stigmas small to large (10)
 - 9(8). Corolla white or lavender, 10-25 mm. long; sepals 3-7 mm. long; inflorescences long-peduncled 5. *Stylisma*, p. 1244.
 9. Corolla bluish purple, about 30-40 mm. long; sepals 10-12 mm. long; peduncle barely developed, the solitary flowers on pedicels shorter than calyx 6. *Bonamia*, p. 1245.
 - 10(8). Stigma with 2 reniform to elliptic thick but flattened lobes 9. *Jacquemontia*, p. 1247.
 10. Stigma globose and undivided or with 2 or 3 subglobose lobes 10. *Ipomoea*, p. 1247.

1. DICHONDRA FORST. & FORST. F.

PONY-FOOT

Creeping or trailing perennials; leaves long-petioled; blades orbicular-ovate to orbicular-reniform, entire; flowers very small, axillary, solitary or paired, long-pedicelled; sepals 5, united at base; corolla shallowly funnelform, deeply 5-lobed, light-green or white; fruit indehiscent or dehiscent, 2- or 4-seeded.

About 15 species, in tropical and warm-temperate regions of both hemispheres.

1. Plants of central, south and east Texas; fruit deeply 2-lobed, indehiscent (2)
1. Plants of Trans-Pecos mountains; fruit not 2-lobed, dehiscent (4)

- 2(1). Pedicel straight; calyx lobes 2 or 3 times as long as wide 1. *D. carolinensis*.
- 2. Pedicel abruptly recurved near summit; calyx lobes 1.5 to 2 times as long as wide (3)
- 3(2). Calyx 1.5-2 mm. long in flower (to 2.5 mm. in fruit); creeping stems mostly less than 1 mm. thick 2. *D. micrantha*.
- 3. Calyx 2.5-3.2 mm. long in flower (to 3.8 mm. in fruit); creeping stems 1-2 mm. thick 3. *D. recurvata*.
- 4(1). Leaf blades silvery-gray with dense appressed pubescence 4. *D. argentea*.
- 4. Leaf blades yellowish to grayish-green, pubescence relatively loose and thin 5. *D. brachypoda*.

1. *Dichondra carolinensis* Michx. Rooting at the nodes, mat-forming, 1-12 cm. high, sparsely pubescent; pedicels one third to two thirds as long as petioles in flower; corolla nearly as long as calyx, light-green. *D. repens* var. *carolinensis* (Michx.) Choisy. Damp open ground, roadsides and lawns, cen. and e. Tex., Mar.-June; e. and n. to Fla. and Va.

2. *Dichondra micrantha* Urban. Rooting at the nodes, mat-forming, 1-6 cm. high, sparsely pubescent; pedicels one fourth to one half as long as petioles; corolla as long as calyx or slightly longer, white. Damp ground and lawns, s. Tex., Apr.-May; adj. Mex., W.I., Pac. Is., e. Asia.

3. *Dichondra recurvata* Tharp & M. C. Johnst. Rooting at the nodes, mat-forming, 2-17 cm. high, rather sparsely pubescent; pedicels one tenth to one half as long as petioles; corolla nearly one third longer than calyx. Gravelly or sandy open oak woods, cen. Tex., Mar.-May; endemic.

4. *Dichondra argentea* H. & B. SILVER PONY-FOOT. Trailing and rooting at lower nodes, mat-forming, 1-5 cm. high, densely appressed-pubescent; pedicels one sixth to one half as long as petioles; corolla nearly twice as long as calyx, whitish. Dry rocky slopes, Trans-Pecos mts., May-Aug.; also Mex.

5. *Dichondra brachypoda* Woot. & Standl. NEW MEXICO PONY-FOOT. Trailing and rooting at nodes, 2-18 cm. high, rather densely pubescent; pedicels one tenth to one third as long as petioles; corolla about one fourth longer than calyx, whitish. Damp or shady rocky ground, Trans-Pecos mts., July-Aug.; also Ariz., N.M. and Mex.

2. PETROGENIA I. M. JOHNST.

One species.

1. *Petrogenia repens* I. M. Johnst. Trailing woody-based perennial, densely appressed-pubescent throughout; stems usually many, sometimes rooting at lower nodes, 1-5 dm. long; leaves very short-petioled; blades entire, elliptic to oblong-elliptic, 6-14 mm. long; flowers axillary, solitary, subsessile; calyx unequally 5-parted, the lobes laterally overlapping (inner ones narrower); corolla 3-3.5 mm. long, shorter than calyx, greenish-yellow, campanulate, 5-lobed; stamens included; styles 2, united at base, filiform; stigmas capitate; capsule 2-celled, 4-seeded, enclosed by calyx. Dry rocky limestone slopes, Brewster and Terrell cos., Apr.-Aug.; also adj. Mex.

3. CRESSA L.

Low densely appressed-pubescent perennials with deep vertical or oblique branching rhizomes, forming colonies; aboveground stems erect or partly decumbent, freely branched; leaves sessile, small, entire; flowers axillary, solitary, short-pedicelled; calyx bracteolate; sepals 5, united at base, laterally overlapping, elliptic; corolla white, funnel-form to subsalverform, 5-lobed, exceeding calyx; stamens exerted; styles 2; stigma capitate; capsule 1- to 4-seeded.

About 6 species of warm-temperate to tropical regions of both hemispheres.

1. Leaf blades well-developed, broadly elliptic to lanceolate, the larger 5-12 mm. long and 1.5-6 mm. wide, those on main stems crowded and overlapping 1. *C. depressa*.
1. Leaf blades very reduced, at flowering time the plant usually with only small bracts 1-4 mm. long and 0.6-2.8 mm. wide, those on main stems widely spaced 2. *C. nudicaulis*.

1. *Cressa depressa* Goodd. Plant densely leafy, gray-pubescent, 8-25 cm. tall. *C. truxillensis* H.B.K. var. *vallicola* (Heller) Munz. In depressions or damp alkaline soil in Trans-Pecos (one specimen from Calhoun Co. on the Gulf Coast, perhaps mislabelled as to locality), Apr.-July; w. to Calif.; Mex.

2. *Cressa nudicaulis* Griseb. LEAFLESS CRESSA. Plant at first with a few very small leaves, appearing leafless or nearly so at flowering time, with bracts only, 7-20 cm. tall. *C. aphylla* Heller. Coastal cos. from San Patricio Co. s., Apr.-May or Sept.; also Arg.

4. EVOLVULUS L

Low perennials with erect to prostrate stems; leaves sessile or subsessile, entire; flowers axillary, solitary or in few-flowered cymes; sepals 5; corolla rotate to shallowly funnel-form, 5-angled or -lobed, blue or lavender to white; styles 2, each with 2 branches; stigmas filiform; ovary 1- or 2-celled; capsule 1- to 4-seeded.

About 100 species, tropical to temperate regions of both hemispheres.

1. Corolla 5-8 mm. across, bluish-white to deep blue 1. *E. alsinoides*.
1. Corolla 8-18 mm. across, white to lavender (2)
- 2(1). Leaf blades densely pilose on both surfaces with loosely appressed to spreading hairs 2. *E. Nuttallianus*.
2. Leaf blades densely pubescent beneath with closely appressed hairs and commonly some loose ones as well, glabrous or loosely pilose above 3. *E. sericeus*.

1. *Evolvulus alsinoides* L. OJO DE VÍBORA. Stems erect to prostrate, pilose, 6-60 cm. long; leaves rather densely pilose on both surfaces, 4-20 mm. long, 2-8 mm. wide; peduncles exceeding the leaves; pedicels exceeding the calyxes.

Var. *hirticaulis* Torr. Stem hairs both widely spreading and appressed; leaf blades elliptic or ovate to oblong-lanceolate, spreading-pilose. Incl. var. *adscendens* (House) v. Ooststr. and var. *debilis* (H.B.K.) v. Ooststr. Cen., s. and w. Tex., all year s., June-Aug. elsewhere.

Var. *angustifolia* Torr. Stem hairs mostly appressed; leaf blades oblong-lanceolate to linear, loosely appressed-pilose. Incl. var. *acapulcensis* (Willd.) v. Ooststr. Trans-Pecos mts., June-Aug.; also Mex.

2. *Evolvulus Nuttallianus* R. & S. Stems erect or partly decumbent, 5-25 cm. long, usually many from a divided or short-creeping root, densely pilose; leaf blades lanceolate to elliptic-oblong, 6-20 mm. long, 1-8 mm. wide, exceeding the flowers; peduncles absent; pedicels shorter than calyxes; corolla lavender to almost white. *E. pilosus* Nutt., *E. mollis* Small. Rocky or sandy ground, throughout except e. Timber Belt., Apr.-July (-Sept.); Ariz. to Mont. and Tenn.

3. *Evolvulus sericeus* Sw. Stems erect to prostrate, 6-35 cm. long, densely appressed-pilose; leaf blades elliptic to linear (upper usually much narrower than lower), 1-3 cm. long, 1-8 mm. wide, usually exceeding the flowers; peduncles very short (except in the rare f. *pedunculatus* v. Ooststr.); pedicels shorter than calyxes; corolla white. Incl. var. *discolor* (Benth.) Gray. Sandy or silty ground, cen., w. and s. Tex., Apr.-Oct.; Calif. to Fla., s. to Arg.

5. STYLISMA RAF.

Perennials with prostrate or ascending straight or twining stems; leaves short-petioled or sessile, entire; inflorescences axillary, peduncled; flowers solitary or few; sepals 5;

corolla funnellform to campanulate, shallowly 5-lobed or -angled, white or lavender; stamens 5, included or exerted; style branches 2, sometimes short or unequal (rarely 1 obsolete); stigmas capitate, minute; capsule 1- to 4-seeded.

Six species, confined to southeastern United States.

- 1. Filaments glabrous or nearly so (2)
- 1. Filaments densely spreading-pilose in lower portion (3)
- 2(1). Corolla lavender; style divided halfway or more ... 1. *S. aquatica*.
- 2. Corolla white; style with branches less than 2 mm. long or undivided 4. *S. Pickeringii* var. *Pattersonii*.
- 3(1). Sepals glabrous on back 2. *S. humistrata*.
- 3. Sepals pilose on back 3. *S. villosa*.

1. *Stylisma aquatica* (Walt.) Raf. Stems prostrate or twining, short-pubescent, to 15 dm. long; leaves short-petioled; blades oblong-elliptic or oblong-lanceolate, truncate or slightly cordate at base, densely short-pubescent on both surfaces, 1-3 cm. long, 3-10 mm. wide; peduncles exceeding leaves; pedicels shorter than calyxes; corolla lavender, 10-15 mm. long. *Breweria aquatica* (Walt.) Gray, *B. Michauxii* Fern. & Schub., *Bonamia aquatica* (Walt.) Gray, *B. Michauxii* (Fern. & Schub.) K. A. Wils. Sandy open ground, especially damp places, rare in s.e. Tex., May-June; Tex. to Ark., Fla. and N.C.

2. *Stylisma humistrata* (Walt.) Chapm. Stems prostrate or twining, sparsely to densely pubescent, to 25 dm. long; leaves short-petioled; blades oblong-elliptic to oblong-lanceolate, the larger slightly cordate at base, sparsely to rather densely pubescent (especially beneath), 1-6 cm. long, 6-30 mm. wide; peduncles exceeding leaves; pedicels shorter than calyxes; corolla white, 16-20 mm. long, *Breweria humistrata* (Walt.) Gray. In sandy soil in usually dry open woods, e. Tex., June-Aug.; Fla. w. to Ark. and Tex., n. to Va.

3. *Stylisma villosa* (Nash) House. Stems prostrate or twining, densely pubescent, to 2 m. long; leaves short-petioled; blades narrowly oblong-elliptic or oblong-lanceolate, rounded-truncate at base, densely pubescent on both surfaces, 1-5 cm. long, 5-20 mm. wide; peduncles exceeding leaves; pedicels shorter than or equaling calyxes; corolla white, about 2 cm. long. *Breweria villosa* Nash, *Bonamia villosa* (Nash.) K. A. Wils. Loose sand, cen. coastal cos., May-June; also Fla.

4. *Stylisma Pickeringii* (Torr.) Gray var. *Pattersonii* (Fern. & Schub.) Myint. Stems trailing or reclining on other plants, inconspicuously though rather densely pubescent, to 2 m. long; leaves sessile or nearly so; blades linear, usually pubescent beneath, glabrous above, 2-6 cm. long, 1-5 mm. wide; peduncles equaling or exceeding leaves; pedicels shorter to longer than calyxes; sepals densely pubescent on back; corolla white, 10-18 mm. long. *S. Pattersonii* (Fern. & Schub.) G. N. Jones, *Breweria Pickeringii* var. *Pattersonii* Fern. & Schub. Sandy open ground, e. and cen. Tex., May-Sept.; Tex. to Kan., Ia., Ill. and La.

6. BONAMIA THOU.

Between 35 and 40 species in tropics and subtropics of both hemispheres.

1. *Bonamia ovalifolia* (Torr.) Hallier f. Perennial from woody base; stems spreading-ascending, densely pubescent, to 5 dm. long; leaves very short-petioled; blades sub-orbicular to oblong-elliptic, entire, rounded to faintly cordate at base, felty-pubescent on both surfaces, 15-25 mm. long, 1-2 cm. wide; flowers axillary, solitary; peduncles barely developed, less than one half as long as pedicels; sepals 5, elliptic-ovate, somewhat leathery, densely pubescent, laterally overlapping, 10-12 mm. long; corolla funnellform-campanulate, 3.5-5 cm. long, blue-purple; style 2-branched; stigmas capitate; capsule 1- to 4-seeded. *Breweria ovalifolia* (Torr.) Gray. In sand, known only from Brewster Co., July-Nov.; also adj. Mex.

7. CONVULVULUS L

Annual or perennial; stems ascending to trailing or twining; leaves petioled or sessile, entire or lobed; flowers axillary, solitary or in loose or congested cymes, both peduncled and pedicelled; calyx with small slender bracts or usually none; corolla funnelform or funnelform-campanulate, 5-angled or very shallowly 5-lobed, white or variously colored; ovary 2-celled; style simple; stigmas 2, linear, more or less flattened, slightly acute; capsule 2- to 4-seeded.

Over 200 species, chiefly in warm-temperate regions of both hemispheres, the majority Old World.

1. Calyx 3-5 mm. long, inconspicuously pubescent or glabrate; perennial from often deep creeping root, forming extensive beds 1. *C. arvensis*.
1. Calyx 6-12 mm. long, densely pubescent; perennial from taproot, sometimes divided at summit but not creeping 2. *C. equitans*.

1. *Convolvulus arvensis* L. BINDWEED, POSSESSION VINE. Stems trailing or twining, to 1 m. long or more, glabrous to rather densely but loosely pubescent; petioles much shorter than to equaling blades; blades highly variable in shape, from oblong-elliptic or deltoid-ovate to narrowly oblong, commonly indented at base and with spreading basal lobes, otherwise entire, glabrous or more or less pubescent (especially beneath), mostly 1-7 cm. long, 6-40 mm. wide; flowers solitary, on peduncles slightly shorter to longer than the leaves; pedicels slightly or much shorter than peduncles, about 1 to 3 times as long as calyxes; sepals elliptic-orbicular, glabrate or loosely pubescent, scarious-margined; corolla open-funnelform, open during morning, white or occasionally pink or lavender-pink, outside with broad vertical bands or wholly tinged pinkish or brownish-lavender. *Strophocaulos arvensis* (L.) Small. Roadsides, railroads, fields, gardens and waste places, Panhandle to cen. and w. Tex.; introd. and spreading, to be expected elsewhere, late Apr.-Sept.; nat. of Euras., now of world-wide distribution.

2. *Convolvulus equitans* Benth. Stems prostrate or twining, to 2 m. long, densely pubescent; petioles mostly one fourth to three fourths as long as blades; blades extremely variable in shape, ovate-elliptic to triangular-lanceolate or narrowly oblong with projecting bases, usually strongly indented at base, entire (rarely) or variously toothed or lobed or both, densely pubescent on both surfaces with loosely appressed hairs, 1-7 cm. long, 2-40 mm. wide; flowers solitary (occasionally in 2's, rarely 3's); peduncles about one half to one and one half times as long as leaves; pedicels much shorter than peduncles, shorter than or to twice as long as calyxes; calyx densely pubescent; sepals often with slightly shouldered to strongly auricled bases; corolla funnelform with rather narrow tubular base, 5-angled (the angles often prolonged as slender points), 1.5-3 cm. long, white to pink, often with red center. *C. hermannioides* Gray, *C. incanus* of auth., not Vahl. Prairies or disturbed ground, especially in rocky or sandy soil, throughout except e. Timber Belt, Feb. (s.) or Apr.-Oct.; Tex. to Kan., Colo., Ariz. and Mex.

8. CALYSTEGIA R. BR. HEDGE-BINDWEED

About 30 species, chiefly in temperate regions of both hemispheres.

1. *Calystegia sepium* (L.) R. Br. Perennial from creeping rhizomes; stems trailing and twining, to 2 m. long; leaves long-petioled; blades abruptly contracted to deeply cordate at base, acuminate at apex; flowers axillary, solitary or paired; peduncle at first much shorter (later becoming longer) than leaves, 1-flowered; floral bracts 2, elliptic-ovate, laterally overlapping, 12-25 mm. long, about twice as long as calyx and concealing it; corolla funnelform, 5-angled, 4-8 cm. long, white; ovary commonly 1-celled; style simple; stigmas oblong to linear, scarcely or not flattened, obtuse; capsule mostly 2- to 4-seeded. *Convolvulus sepium* L.

Var. *fraterniflora* (Mack. & Bush) Shinn. Leaf blades deltoid-ovate to oblong-ovate, glabrous to rather densely pubescent on both surfaces, mostly 4-8 cm. long, 2.5-5 cm. wide, the basal lobes rather widely spreading with the broad sinus open. *C. fraterniflora*

(Mack. & Bush) Brummitt, *Convolvulus fraterniflorus* Mack. & Bush, *C. septium* var. *fraterniflorus* Mack. & Bush. Stream banks, rare in far n. and n.e. Tex. (known only from Ochiltree, Cooke and Anderson cos.), May-Oct.; cen. U.S.

Var. *repens* (L.) Gray. Leaf blades narrowly deltoid-ovate to deltoid-lanceolate, usually densely soft-pubescent on both surfaces (rarely glabrate), mostly 4-9 cm. long, 2.5-5 cm. wide at base, rather abruptly contracted above base to an oblong-lanceolate main portion 1-2 cm. wide, the basal lobes directed backward (parallel with petiole) or somewhat spreading with the sinus narrow to moderately broad. *Convolvulus septium* var. *repens* (L.) Gray. Rare on Gulf Coast and lower Rio Grande, July; Gulf and Atl. coasts, rarely inland.

9. JACQUEMONTIA CHOISY

About 120 species, tropical and subtropical regions of both hemispheres.

1. *Jaquemontia tamnifolia* (L.) Griseb. Annual, flowering while small and erect; stem and branches becoming elongate and twining, to 2 m. long, sparsely to densely pilose; leaves moderately long-petioled; blades ovate or elliptic-ovate, acute, mostly 3-12 cm. long, 2-9 cm. wide, pilose on margins and sometimes sparsely so on surfaces, the larger ones cordate at base; peduncles at first shorter (ultimately longer) than the leaves; flowers many, in a nearly capitate axillary leaf-bracted cyme; sepals 5, separate, lance-linear, hispid-pilose, about two thirds as long as corolla; corolla blue, funnellform-campanulate, 5-angled, 12-16 mm. long; stamens 5; style simple; stigmas 2, more or less flattened, elliptic or oblong; capsule 4-seeded. *Thyella tamnifolia* (L.) Raf. Roadsides, stream beds, cult. or disturbed ground, e. Tex., July-Oct.; s.e. U.S. to Braz.

10. IPOMOEA L. MORNING GLORY

Annual or perennial herbs or woody vines, shrubs or trees; stems erect to trailing, creeping or twining and climbing; leaves sessile to long-petioled, simple or palmately compound (in one species pinnately cut almost to midrib, appearing compound), entire or toothed or shallowly to deeply lobed; flowers axillary or terminal, solitary to numerous; peduncles and pedicels various; sepals 5, commonly laterally overlapping; corolla 5-angled or shallowly 5-lobed, salverform to funnellform or campanulate, usually large, variously colored, usually open for less than 24 hours (morning, daytime or night); stamens included or exserted; ovary 1- to 3-celled; style simple; stigma globose or with 2 or 3 globose lobes; capsule 1- to several-seeded, variously dehiscent or (a few species) indehiscent.

Over 600 species (often referred to 6 to 10 unsatisfactorily distinguishable genera), warm-temperate and tropical regions of both hemispheres. (Incl. *Batatas*, *Calonyction*, *Exogonium*, *Merremia*, *Mina*, *Operculina*, *Pharbitis*, *Quamoclit*, *Turbina*.)

See explanation at end of key.

1. Corolla more or less strongly salverform, the long narrow tube only slightly widened to near or above middle, rather abruptly flaring near summit, at mid-level 3-7 mm. in diameter, the maximum breadth at summit (corolla rim) 5 to 20 times as great as mid-level diameter (2)
1. Corolla funnellform to campanulate, with short to rather long tube gradually expanding from below middle (but often more sharply flaring near summit), at mid-level 4-20 mm. in diameter, the maximum breadth at summit (corolla rim) 2 to 5 times as great as mid-level diameter (9)
- 2(1). Corolla 6-14 cm. long, lavender or white (partly green outside); flowers open during night and first part of morning (3)
2. Corolla 2-3.5 cm. long, red to orange or yellow (very rarely all white); flowers open all morning or all day (5)
- 3(2). Sepals obtuse3. *I. Tuba*.
3. Sepals with abrupt prominent soft-spiny tips (4)

- 4(3). Corolla white with vertical green bands outside; sepals 14-28 mm. long
 1. *I. alba*.
4. Corolla lavender or pinkish lavender; sepals 8-13 mm. long
 2. *I. muricata*.
- 5(2). Leaf blades divided more than halfway to midrib, with narrowly linear to lanceolate acute segments (6)
5. Leaf blades entire, angled or shallowly to deeply 3- to 7-lobed, the lobes broad or narrow but obtuse (7)
- 6(5). Leaf blades all pinnately cut almost to midrib, the segments narrowly linear (about as wide as narrowly margined midrib), the leaf appearing pinnately compound 4. *I. Quamoclit*.
6. Leaf blades more or less palmately cut, not divided to midrib, the segments lanceolate 5. *I. × multifida*.
- 7(5). Calyx 4-4.5 mm. long 7. *I. hederifolia*.
7. Calyx (5-) 6-8 mm. long (8)
- 8(7). Leaf blades entire or angled-toothed 6. *I. coccinea*.
8. Leaf blades (some or all) distinctly 3- to 7-lobed 8. *I. cristulata*.
- 9(1). Pedicels and peduncles with reflexed hairs (sometimes also some spreading ones) (10)
9. Pedicels and peduncles glabrous or with widely spreading to ascending hairs or soft spreading to slightly down-curved prickles (15)
- 10(9). Sepals soft-pilose or pubescent on back with slender hairs
 9. *I. acuminata*.
10. Sepals hispid-pilose on back, the hairs (at least those toward pedicel) with swollen bases (11)
- 11(10). Perennial with tough or stout root usually divided at summit and producing several main stems (12)
11. Annual with slender to somewhat coarse taproot producing one main stem (13)
- 12(11). Body of outer sepals cordate- or triangular-ovate, 6-12 mm. wide
 10. *I. pubescens*.
12. Body of outer sepals ovate-lanceolate to narrowly lanceolate, 3-9 mm. wide
 11. *I. Lindheimeri*.
- 13(11). Sepals with slightly narrowed green tips shorter to slightly longer than body ..
 14. *I. purpurea*.
13. Sepals with very narrow elongate green tips much longer than body (14)
- 14(13). Sepals abruptly narrowed, the long subacute tips strongly spreading or curved .
 13. *I. hederacea*.
14. Sepals gradually narrowed, the long acute tips suberect, straight, scarcely spreading
 12. *I. Nil*.
- 15(9). Anthers large and strongly spirally twisted when flowers have opened (16)
15. Anthers large or small, straight or merely slightly curved (17)
- 16(15). Sepals with broadly rounded obtuse tips; corolla white
 33. *I. pinnatifida*.
16. Sepals rounded but with abrupt short sharp points; corolla white with purple-red center 32. *I. sinuata*.
- 17(15). Leaf blades divided to base, the lobes or leaflets narrow (18)
17. Leaf blades entire or with broad or irregular lobes, not divided to base (23)
- 18(17). Sepals hispid-pilose on back 15. *I. barbatisepala*.
18. Sepals glabrous or merely warty-roughened on back (19)
- 19(18). Outer sepals ovate-oblong, less than twice as long as wide (20)
19. Outer sepals oblong to oblong-lanceolate, more than twice as long as wide (21)

- 20(19). Corolla 4-6 cm. long16. *I. cairica*.
 20. Corolla 1.5-2.3 cm. long17. *I. Wrightii*.
 21(19). Corolla 4-9 cm. long18. *I. tenuiloba*.
 21. Corolla 1-3 cm. long (22)
 22(21). Corolla 2-3 cm. long; perennial with woody-tuberous root
19. *I. capillacea*.
 22. Corolla 1-1.5 cm. long; annual with slender taproot ... 20. *I. costellata*.
 23(17). Stems rooting at nodes, long-creeping (24)
 23. Stems not rooting at nodes, trailing to erect or twining and climbing (25)
 24(23). Leaf blades mostly irregularly lobed; sepals oblong-lanceolate, much longer
 than wide21. *I. stolonifera*.
 24. Leaf blades entire except for notched apex; sepals suborbicular, nearly as wide
 as long or wider22. *I. Pes-caprae*.
 25(23). Leaf blades linear-lanceolate to narrowly rhombic- or ovate-lanceolate, with
 narrowed base (26)
 25. Leaf blades triangular to cordate-ovate or sagittate, with truncate or indented
 base (27)
 26(25). Leaf blades linear-lanceolate; petioles on flowering branches 2-8 mm. long
23. *I. leptophylla*.
 26. Leaf blades narrowly rhombic- or ovate-lanceolate; petioles on flowering branches
 (except terminal portion) 10-25 mm. long24. *I. Shumardiana*.
 27(25). Sepals with prominent white or pale scarious or subscarious margins (28)
 27. Sepals not with prominent white or pale scarious or subscarious margins (30)
 28(27). Sepals oblong-lanceolate, slightly contracted or rounded-auricled at base;
 woody vine36. *I. corymbosa*.
 28. Sepals triangular-lanceolate, not contracted or auricled at base; herbaceous vines (29)
 29(28). Corolla 1.5-2.5 cm. long; sepals more or less warty-roughened on back; native
 in Trans-Pecos mountains34. *I. cardiophylla*.
 29. Corolla 6-9 cm. long; sepals smooth on back; cultivated
35. *I. tricolor*.
 30(27). Sepals finely gray-pubescent on back; plant an erect coarse perennial herb
 or shrub38. *I. fistulosa*.
 30. Sepals glabrous or hispid-pilose or softly prickly on back; plant trailing or
 twining (31)
 31(30). Sepals about equal in length (32)
 31. Sepals markedly unequal in length, the outer three fourths to five sixths as long as
 the inner (37)
 32(31). Sepals suborbicular, obtuse or broadly rounded at apex (sometimes very
 inconspicuously notched or mucronate)29. *I. amnicola*.
 32. Sepals elliptic to oblong-lanceolate, strongly mucronate or acute to acuminate (33)
 33(32). Petioles and stems with slightly fleshy spreading (but often downwardly
 curved) prickles or bristles37. *I. melanotricha*.
 33. Petioles and stems glabrous or with slender to ascending hairs (34)
 34(33). Sepals hispid on back with widely spreading hairs .15. *I. barbatissepala*.
 34. Sepals glabrous or with slender ascending hairs (35)
 35(34). Sepals 15-22 mm. long in flower; corolla 5.5-9 cm. long
 9. *I. acuminata*.
 35. Sepals 6-13 mm. long in flower; corolla 1.8-5.5 cm. long (36)
 36(35). Corolla 28-55 mm. long30. *I. trichocarpa*.
 36. Corolla 18-23 mm. long31. *I. lacunosa*.

- 37(31). Corolla white with purple-red center 25. *I. pandurata*.
 37. Corolla all lavender-pink to red-purple (38)
 38(37). Sepals distinctly short-awned; cultivated 26. *I. Batatas*.
 38. Sepals merely mucronate or subacute to obtuse; wild (39)
 39(38). Leaf blades acuminate 27. *I. sagittata*.
 39. Leaf blades broadly acute or subacute 28. *I. rupicola*.

NOTE: The species are arranged in artificial groups, to reduce repetition in the descriptions and make possible some identification of fruiting material.

GROUP 1.

Annual or perennial glabrous (but often fleshy-prickly) vines; leaf blades cordate, entire or angled-dentate; flowers large; sepals in nos. 1 and 2 with soft spinelike tips; corolla salverform.

1. *Ipomoea alba* L. MOONFLOWER. High-climbing annual; leaf blades cordate-ovate, acute or acuminate, those on flowering shoots 8-20 cm. long, 7-15 cm. wide; peduncles 1- to several-flowered; pedicels thickened toward summit; corolla white with green vertical bands outside. *I. Bona-nox* L., *Calonyction aculeatum* (L.) House, *C. Bona-nox* (L.) Bojer. Commonly cult., June-Nov.; nat. of trop. Am.

2. *Ipomoea muricata* (L.) Jacq. PURPLE MOONFLOWER. Similar to preceding except for smaller flowers with pinkish-lavender or light-purple corollas. *Calonyction muricatum* (L.) G. Don. Occasionally cult., June-Nov.; nat. of trop. Am.

3. *Ipomoea Tuba* (Schlecht.) G. Don. RAILROAD VINE. Perennial, trailing or low-climbing; leaf blades cordate-orbicular to cordate-ovate, acute to short-acuminate; peduncles rather short, 1- to few-flowered; sepals obtuse; corolla white. *I. violacea* L. in part, *nom. conf.* Sandy beaches, known only from Jefferson Co., Oct.-Nov.; also Fla. and W.I.

GROUP 2.

Annual, glabrous or nearly glabrous vines; leaf blades entire or angled-lobed to deeply divided; peduncles elongate, 1- to many-flowered; flowers small, open all day; sepals with soft spinelike tips; corolla salverform, red (sometimes with yellow center, rarely all yellow), 2-4 cm. long, to 3 cm. broad.

4. *Ipomoea Quamoclit* L. CYPRESS VINE. Rather low-climbing; leaves short-petioled; blades oblong-elliptic in outline, pinnately cut into many narrowly linear segments about as wide as the narrowly margined midrib; peduncles 1- to few-flowered; corolla deep-red. *Quamoclit pennata* Bojer, *Q. Quamoclit* (L.) Britt. Cult.; once collected presumably wild in Brazos Co., July-Nov.; nat. of s.e. U.S.

5. *Ipomoea* × *multifida* (Raf.) Shinn. Leaf blades broadly ovate or ovate-oblong in outline, deeply cut (mostly two thirds to three fourths to midrib or base) into many narrowly lanceolate segments; corolla deep-red, throat changing to yellow. *I.* × *Sloteri* (Nieuw.) v. Ooststr. (Hybrid of *I. Quamoclit* and *I. coccinea*.) Cult., July-Nov.; of garden origin.

6. *Ipomoea coccinea* L. SCARLET CREEPER. Low-climbing vine; leaf blades ovate, shallowly to deeply cordate, entire or angled-toothed, acuminate, those on flowering branches 3-7 cm. long, 3-7 cm. broad; peduncles 1- to several-flowered; corolla orange-red or red with yellow tube. *Quamoclit coccinea* (L.) Moench. Commonly cult., seeding itself and tending to escape, July-Nov.; nat. of s.e. U.S.

7. *Ipomoea hederifolia* L. Similar to *I. coccinea*; leaf blades variable, commonly quadrate-ovate to quadrate-reniform in outline, 3-lobed. *I. coccinea* var. *hederifolia* (L.) Gray, *Quamoclit hederifolia* (L.) G. Don. Damp thickets near the coast, Orange Co. to Matagorda Co., also cult. and escaped inland, July-Nov.; Fla. to Tex.; W.I. and Mex.

8. *Ipomoea cristulata* Hallier f. Similar to *I. coccinea*; leaf blades distinctly lobed, often deeply dissected. In canyons, Trans-Pecos mts., also cult., Aug.-Oct.; Tex. to Ariz. and cen. Mex. This species and *I. hederifolia* have been generally confused with *I. coccinea* and pass for it in cultivation.

GROUP 3.

Annual or perennial vines; leaf blades mostly cordate-ovate in outline, entire or shallowly to deeply lobed; peduncles and pedicels with reflexed hairs (except in *I. barbatisepala* and sometimes *I. acuminata*); corolla funnelform, blue or purple to red or white.

9. *Ipomoea acuminata* (Vahl) R. & S. Low- to high-climbing perennial vine, glabrous or pubescent; leaf blades cordate-ovate, acuminate, entire to deeply 3-lobed, glabrous to densely soft-pubescent beneath, those on flowering shoots 4-16 cm. long, 3-12 cm. wide; peduncles long, several- to many-flowered; sepals narrowly ovate-lanceolate, acuminate; corolla red-purple, 6-9 cm. long. *I. cathartica* Poir., *I. congesta* R. Br., *I. Leari* Paxt., *I. mutabilis* Lindl., *Pharbitis cathartica* (Poir.) Choisy. Damp thickets and waste ground, s. Tex.; also cult., Mar.-Nov.; Fla. to Tex.; W.I., Mex., S.A. and Old World. All Texas collections are of the form with pilose stems and densely soft-pubescent leaves and sepals.

10. *Ipomoea pubescens* Lam. Low-climbing or trailing gray-pubescent perennial vine; leaf blades cordate-ovate to suborbicular in outline, those on flowering shoots 3-7 cm. long and wide, deeply 3- to 7-lobed (rarely subentire), the lobes ovate-lanceolate to narrowly lanceolate and commonly narrowed toward base; peduncles 1- to several-flowered; corolla reddish-purple, 4-6 cm. long. *I. heterophylla* Ort. Rocky slopes and dry stream beds, Trans-Pecos mts., July-Sept.; w. Tex. to Ariz. and Mex.; also n. S.A.

11. *Ipomoea Lindheimeri* Gray. Similar to *I. pubescens*; sepals narrower, long-acuminate; corolla blue-lavender, sometimes with pale or white center, 6-10 cm. long. *Pharbitis Lindheimeri* (Gray) Small. Rocky ground, especially in draws, ravines and stream bottoms, Edwards Plateau to Trans-Pecos, Apr.-Oct. endemic.

12. *Ipomoea Nil* (L.) Roth. MORNING GLORY. Annual low- to high-climbing vine; stems moderately to densely pilose; leaf blades cordate-ovate to oblong-ovate in outline, mostly 3-lobed (often hastate), acuminate, those on flowering shoots 3-16 cm. long, 2.5-15 cm. wide; peduncles short to long, 1- to several-flowered; sepals hispid-pilose on back; corolla variously colored (chiefly red, purple or blue, often with white center), 5-8 cm. long or more. *Pharbitis Nil* (L.) Choisy. Commonly cult., July-Nov.; nat. probably of Braz., early introd. around the world. Japanese Imperial morning glories are descended from this species.

13. *Ipomoea hederacea* Jacq. Similar to *I. Nil*; leaf blades cordate-ovate, entire or usually 3-lobed; peduncles 1- to few-flowered; corolla lavender to blue with white center in wild plants, varying to purple or red in cult. forms, 3-5 cm. long (slightly larger in cult.). Incl. var. *integriuscula* Gray, *I. barbiger* Sims. Gravel bars, stream banks, fields and disturbed ground, e. Tex. w. to West Cross Timbers s. to Rio Grande, locally up river to Big Bend, also commonly cult. and locally escaped, July-Nov.; s.e. U.S. to W.I. and Mex.

14. *Ipomoea purpurea* (L.) Roth. Similar to *I. Nil* and especially *I. hederacea*; corolla blue-purple to red or white, 4-6 cm. long (slightly larger in cult.); July-Nov.

Var. *purpurea*. Leaf blades cordate, entire. *Pharbitis purpurea* (L.) Voigt. Commonly cult., locally escaped in waste places and disturbed ground; nat. of s.e. U.S.

Var. *diversifolia* (Lindl.) O'Donell. Leaf blades (some or all) 3-lobed. Canyons and stream banks, w. Edwards Plateau and Trans-Pecos mts., rare; Tex. to Ariz. and Mex.

15. *Ipomoea barbatisepala* Gray. Low-climbing glabrous (except sepals) annual vine; leaf blades orbicular-ovate in outline, deeply 5- or 7-lobed, the lobes lanceolate and narrowed toward base; peduncles rather short, 1- or 2-flowered; sepals hispid-pilose on back, with elongate narrowly linear tips; corolla light-rosy-purple, about 2-2.5 cm. long. Type collected by Charles Wright in 1849 near El Paso, the only Tex. record; w. Tex. to Ariz.

GROUP 4.

Glabrous annual or perennial vines or erect herbs with palmately compound leaves (or blades so deeply cut as to appear compound); peduncles 1- to few-flowered; corolla pale-lavender-pink to red-purple.

16. *Ipomoea cairica* (L.) Sweet. Low-climbing vine; leaflets 3 to 7, rhombic to lanceolate, acute or obtuse and mucronate, 2-6 cm. long, the lowest often 2-lobed;

peduncles rather short and thick; sepals broadly oblong-elliptic, obtuse. Collected in heavy soil, San Patricio Co., also cult., July; nat. of Afr.

17. *Ipomoea Wrightii* Gray. Vegetative parts and sepals as in *I. cairica*; peduncles slender, short at first and on youngest branches, becoming very elongate and spirally twisted or coiled. *I. heptaphylla* (Roxb.) Voigt, illegit. name, *I. spiralis* House, *I. pulchella* of auth., not Roth. Alluvial or damp silty or clayey soil, locally abundant in cen. and s. Tex., June-Oct.; nat. probably of India, now widespread in warm countries around the world.

18. *Ipomoea tenuiloba* Torr. Low twining perennial; leaves short-petioled; leaflets narrowly linear; peduncles 1-flowered; sepals oblong-lanceolate, acuminate; corolla pale-pink, 5-8 cm. long. Slopes and summits, Trans-Pecos mts., July-Sept.; w. Tex. to Ariz. and Mex.

19. *Ipomoea capillacea* (H.B.K.) G. Don. Perennial from underground tuber; stems ascending to erect, 8-50 cm. long; leaves sessile; segments or leaflets usually 5, narrowly linear, 5-15 mm. long; peduncles short, filiform, 1-flowered; sepals broadly lanceolate, acute; corolla reddish-purple, 3-4 cm. long. *I. muricata* Cav., not (L.) Jacq., *I. patens* (Gray) House, *I. muricatisepala* Matuda. Dry slopes, Trans-Pecos mts., rare, July-Sept.; w. Tex. to Ariz., s. to n.w. S.A.

20. *Ipomoea costellata* Torr. Low annual from slender taproot; stems at first erect, in age trailing and slightly twining, 12-50 cm. long; leaves sessile or subsessile; leaf segments 5 to 9, narrowly linear or linear-lanceolate, 7-25 mm. long; peduncles rather long, slender, 1- or 2-flowered; sepals oblong-lanceolate, acute, scarious-margined; corolla pale-lavender or pink, 1-1.2 cm. long. Rocky slopes, Trans-Pecos mts., July-Sept.; w. Tex. to Ariz.

GROUP 5.

Glabrous perennials of sandy coastal dunes and beaches; stems prostrate and rooting at nodes, not twining; leaf blades rather fleshy or leathery; sepals elliptic-oblong or orbicular; corolla large.

21. *Ipomoea stolonifera* (Cyr.) Gmel. BEACH MORNING GLORY. Leaf blades varying from oblong-ovate or broadly short-oblong and entire with obtuse to truncate or emarginate apex to deeply and unequally 3- to 7-lobed, 2-4 cm. long, 1-4 cm. wide; peduncles 1-flowered; sepals elliptic-oblong; corolla white with yellow center, 4.5-7 cm. long. *I. littoralis* (L.) Boiss., not Bl. Beaches and dunes along Gulf Coast, Apr.-Nov.; warm regions around the world.

22. *Ipomoea Pes-caprae* (L.) Sweet var. *emarginata* Hallier f. RAILROAD VINE, GOAT-FOOT MORNING GLORY. Leaf blades suborbicular, entire but more or less deeply notched at apex, 4-10 cm. long and wide; peduncles 1- or usually several-flowered; sepals elliptic-orbicular; corolla rosy or purple, 5-7 cm. long. Incl. subsp. *brasiliensis* (L.) v. Ooststr. Beaches and dunes along Gulf Coast, June-Nov.; warm regions around the world.

GROUP 6.

Glabrous or pubescent perennials (except *I. lacunosa*); stems erect to trailing or twining; leaf blades linear-lanceolate to cordate-ovate, entire or lobed; sepals markedly unequal in length (except *I. amnicola*); corolla small to large, funnellform or funnellform-campanulate, white to red-purple.

23. *Ipomoea leptophylla* Torr. BUSH MORNING GLORY. Glabrous, decumbent to erect, bushy-branched, to 1.2 m. tall; petioles 1-7 mm. long; leaf blades linear-lanceolate, 3-9 cm. long, 2-8 mm. wide; peduncles short, stout, 1- to several-flowered; sepals elliptic-orbicular-ovate; corolla lavender-pink with dark center or all purple-red, 6-9 cm. long. Sandy prairies or disturbed ground, Panhandle to Edwards Plateau, e. to Clay Co., s.w. to Winkler Co., late May-July; Tex. to Neb., Colo. and N.M.

24. *Ipomoea Shumardiana* (Torr.) Shinn. Glabrous, trailing or ascending to twining; petioles 5-36 mm. long; leaf blades deltoid-ovate to narrowly ovate-lanceolate, 3-8 cm. long, 1-4 cm. wide; peduncles 1- to several-flowered; sepals oblong-elliptic to oblong-orbicular; corolla pink to white with purple-red center, 5-8 cm. long. *I. Carletoni* Holz.;

has been incorrectly referred to *I. longifolia* Benth.; believed by Robert Pearce to be a hybrid of *I. leptophylla* and *I. pandurata*. Sandy or sandy clay prairies, rare, Red River (Cooke Co.) s. to Edwards Plateau, June-Aug.; also Okla.

25. *Ipomoea pandurata* (L.) Mey. WILD POTATO. Glabrous or pubescent, trailing or twining and low-climbing from woody tuberous root; petioles 1-8 cm. long; leaf blades cordate or cordate-ovate, often with indented sides and almost 3-lobed, 3-10 cm. long, 2-9 cm. wide, glabrous to densely soft-pubescent beneath; peduncles 1- to several-flowered; sepals oblong-elliptic; corolla white with purple-red center, 5-8 cm. long. Thickets, fields and roadsides, e. Tex. w. to Bexar, Blanco and Johnson cos., June-Sept.; s.e. U.S.

26. *Ipomoea Batatas* (L.) Lam. SWEET POTATO, YAM. Glabrous, trailing or twining, from soft-tuberous root; leaf blades highly variable, deltoid-ovate in outline, mostly indented at base, entire to deeply 3- or 5-lobed, 4-10 cm. long and wide; peduncles 1- to several-flowered; sepals oblong-lanceolate, acuminate; corolla pink to purplish, 4-7 cm. long. Cult., especially in e. Tex., May-Sept.; known only as a cult. plant, originating in trop. Am.

27. *Ipomoea sagittata* Poir. Glabrous, tightly twining, low-climbing, from creeping root; leaf blades deeply sagittate, deltoid-lanceolate to narrowly ovate-lanceolate in outline, entire, 4-10 cm. long, 1-5 cm. wide (across base); peduncles 1-flowered; sepals oblong-elliptic, apex broadly rounded with an abrupt small point; corolla red-purple, 6-9 cm. long. Beaches and dunes along Gulf Coast, rarely inland up Rio Grande to Val Verde Co., Apr.-Oct.; Tex. to Fla. and W.I.; also w. Medit., where probably an early introd.

28. *Ipomoea rupicola* House. Glabrous, trailing or low-climbing; petioles with small fleshy points; leaf blades cordate-ovate to ovate-oblong, often with indented sides, entire or occasionally lobed-toothed toward base, 3-9 cm. long, 2-7 cm. wide; peduncles 1- to few-flowered; sepals oblong-elliptic to oblong-ovate, subacute; corolla purple to lavender-pink with dark center, 7-9 cm. long. Rocky open ground, Rio Grande Valley from Hidalgo and Duval cos. to Big Bend, June-Oct.; also adj. Mex.

29. *Ipomoea amnicola* Morong. Glabrous, twining, low-climbing, from creeping root; leaf blades cordate-ovate, entire, 2-6 cm. long, 2-7 cm. wide; peduncles several- to many-flowered, rather short; sepals oblong-orbicular; corolla white with purple-red center, 2-4 cm. long. Fields, ditch banks and roadsides, common in lower Rio Grande Valley, locally n. to Bexar Co., Apr.-July; nat. of Parag., introd. in s. Tex., adj. Mex. and n. S.A.

30. *Ipomoea trichocarpa* Ell. Perennial but flowering first year, from branched root, twining and low-climbing; leaf blades very variable, cordate-ovate in outline, entire to deeply 3- or 5-lobed, 2-8 cm. long, 1.5-7 cm. wide; peduncles 1- to several-flowered; sepals oblong-elliptic, acuminate; corolla rosy-lavender to purple-rose with dark center (rarely white), 2.8-5.5 cm. long. *I. commutata* R. & S., *I. carolina* (L.) Pursh, not L.; has been incorrectly referred to the related tropical species *I. triloba* L. and *I. trifida* H.B.K. Thickets, fields, roadsides and disturbed ground, June-Oct.

Var. *trichocarpa*. Sepals hispid-pilose, at least on margins; stem and leaves glabrous to moderately densely hispid-pilose. Common in e. third of Tex. (but absent from cos. near Red River), local w. to Medina and Menard cos.; s.e. U.S.

Var. *Torreyana* (Gray) Shinnery. Sepals glabrous; stem and leaves glabrous. Common in cen. Tex., from Dallas, Throckmorton, Sutton and Val Verde cos. to lower Rio Grande Valley, rare in e. Tex. (Cass and Nacogdoches cos., perhaps introd.); also Mex.

31. *Ipomoea lacunosa* L. Annual from slender taproot, sparsely to rather densely hispid-pubescent, twining and low-climbing; leaf blades variable, cordate-ovate to deltoid-ovate in outline, entire or angled-toothed or 3-lobed, 2-10 cm. long, 1.5-9 cm. wide; peduncles 1- or 2-flowered; sepals oblong-elliptic, acuminate; corolla white (rarely rosy), 1.8-2.3 cm. long. Damp thickets, stream banks and ditches, common in e. Tex., w. and s. to Tarrant, Travis and Matagorda cos., Sept.-Oct.; s.e. U.S.

GROUP 7.

Perennial vines; leaf blades deeply lobed or compound; sepals oblong-elliptic to suborbicular; corolla large, white or white with purple-red center; anthers large, spirally twisted.

32. *Ipomoea sinuata* Ort. ALAMO VINE, CORREHUELA DE LAS DOCE. Trailing to low-climbing; stem and petioles glabrous or spreading-pilose; leaf blades ovate-orbicular in outline, 4-15 cm. long and wide, palmately deeply 5- or 7-lobed, the lobes dentate to pinnatifid, obtuse; peduncles 1- or 2-flowered; sepals oblong-elliptic, mucronate; corolla white with purple-red center, 3.5-5 cm. long. *I. dissecta* (Jacq.) Pursh, not L., *Merremia dissecta* (Jacq.) Hallier f., *Operculina dissecta* (Jacq.) House. Stream banks, open ground and disturbed places, s.-cen. Tex. (Travis to Galveston and Val Verde cos. and s.), also cult., May-Nov.; Tex. and Fla. to W.I., Mex. and S.A.

33. *Ipomoea pinnatifida* (H.B.K.) G. Don. Glabrous, low-climbing; leaf blades orbicular-ovate to oblong-ovate in outline, 3-11 cm. long, 2-9 cm. wide, mostly deeply subpinnately 5- or 7-lobed, the lobes rhombic-elliptic to narrowly lanceolate, usually dentate or again lobed; peduncles 1- or 2-flowered; sepals elliptic-orbicular; corolla white, 3-5 cm. long. *I. ornithopoda* Robins., *Operculina pinnatifida* (H.B.K.) O'Donell. Pastures and open or brushy ground, Nueces Co. southw., rare, July-Sept.; also Mex.

GROUP 8.

Annual or perennial vines, glabrous or (*I. corymbosa* sometimes) pubescent; leaf blades entire; peduncles 1- to many-flowered; sepals with prominent white or pale borders; corolla funnelform.

34. *Ipomoea cardiophylla* Gray. Glabrous low-climbing annual; leaf blades cordate; peduncles 1- or 2-flowered; sepals ovate-lanceolate, acute, warty-wrinkled or roughened on back; corolla blue-purple, about 2-3 cm. long. Trans-Pecos mts., local, Aug.-Oct.; endemic.

35. *Ipomoea tricolor* Cav. MORNING GLORY. Glabrous annual high-climbing vine; leaf blades cordate, acuminate, 5-15 cm. long, 4-12 cm. wide; peduncles several- to many-flowered; sepals ovate-lanceolate, acute; corolla blue or purple to red or white or multicolored, 5-9 cm. long. Commonly cult., July-Oct.; nat. of Mex.

36. *Ipomoea corymbosa* (L.) Roth. CHRISTMAS VINE. Woody high-climbing vine, glabrous or rarely with leaf blades densely pubescent beneath; leaf blades broadly to narrowly cordate-ovate; peduncles many-flowered; sepals oblong-elliptic or oblong-lanceolate, mucronate; corolla white, 2-3 cm. long. *I. sidaefolia* (H.B.K.) Choisy, *Turbina corymbosa* (L.) Raf. Reported from Tex. by Small, but there is no voucher specimen, possibly cult. in extreme s. Tex., Dec.-Feb.; trop. Am., naturalized in s. Fla.

GROUP 9.

Robust annual high-climbing vines, with fleshy soft prickles or bristles; leaf blades suborbicular in outline, deeply 5- to 9-lobed; corolla large, funnelform-campanulate.

37. *Ipomoea melanotricha* Brandeg. Glabrous except for spreading soft prickles on stem and petioles and blackish bristles on sepals; corolla red-purple, 7-9 cm. long. Cult. in Brownsville area; nat. of Mex.

GROUP 10.

Sprawling to erect perennial herb or shrub, glabrous to upper petioles, inflorescence and sepals minutely pubescent; leaf blades narrowly ovate-lanceolate, acuminate, entire, with shallowly to deeply cordate base; flowers terminal, cymose-panicled; corolla large, lavender with dark center.

38. *Ipomoea fistulosa* Mart. SHRUBBY MORNING GLORY. Cult. as far n. as Dallas, where freezing to the ground, becoming to 2 m. tall in growing season; established as an escape in lower Rio Grande Valley, where an arborescent shrub to 5 m. tall; leaf blades 7-30 cm. long, 4-15 cm. wide; corolla 6-9 cm. long. *I. crassicaulis* (Benth.) Robins. All year; nat. of trop. Am., widely cult. and escaped n. to Fla. and Tex.

11. CUSCUTA L.¹⁵⁴

DODDER. LOVE-VINE

Plants leafless and rootless, herbaceous, parasitic; stems yellowish or orange-color, filiform, fleshy-herbaceous, glabrous, twining; flowers small (mostly 2-6 mm. long), sessile or short-pedicellate, in few- to many-flowered cymose clusters, commonly 5-merous but sometimes 3- or 4-merous; perianth parts mostly united; corolla campanulate to cylindric, shallowly or deeply lobed; stamens inserted in the throat of the corolla, alternating with the usually longer lobes; scalelike toothed, fringed or fimbriate appendages commonly present at base of the corolla tube opposite the stamens; ovary 2-celled, stigmas linear to capitate; fruit a capsule, indehiscent or sometimes opening with a regular or irregular line of circumscission near the base; embryo acotyledonous, filiform or more or less enlarged at one end.

About 170 species, mostly in the Americas. Some species may exhibit a host preference, but most will grow upon a wide range of herbaceous or woody plants including pteridophytes and grasses. A few species show a predilection for cultivated crop plants, especially legumes and flax, and sometimes cause considerable damage. While commonly considered to be wholly parasitic, many species show evidences of chlorophyll in the stems, flowers or maturing fruits and are, therefore, at least partly autophytic. Additional vernacular names to those above are "angel's hair," "tangle gut," "witches' shoelaces," "devil's gut," "strangle vine."

- 1. Styles coherent; flowers sessile; infrastamineal scales represented by wings; capsules to 1 cm. long24. *C. exaltata*.
- 1. Styles entirely separate and distinct from each other; capsules much less than 1 cm. long (2)
- 2(1). Capsules not circumscissile (that is, not separating in a regular line of cleavage), when forcibly separated either coming away entirely or breaking very irregularly (3)
- 2. Capsules circumscissile (that is, easily separating near the base in a more or less regular line of cleavage) (22)
- 3(2). Calyx gamosepalous; inflorescence not markedly bracteate or congested (4)
- 3. Calyx deeply divided to form distinct or nearly distinct sepals; inflorescence with numerous bracts, loose or mostly compact (19)
- 4(3). Styles short and subulate; interstylar aperture comparatively large; calyx lobes commonly unequal (5)
- 4. Styles longer and slightly (if at all) subulate (6)
- 5(4). Flowers mostly 5-parted1. *C. obtusiflora* var. *glandulosa*.
- 5. Flowers mostly 3- or 4-parted2. *C. Polygonorum*.
- 6(4). Flowers 3- or 4-parted; withered corolla capping the capsule3. *C. Cephalanthi*.
- 6. Flowers 5-parted; withered corolla not capping the capsule (7)
- 7(6). Calyx conspicuously 5-angled by the projecting lobes where they overlap at the sinuses4. *C. pentagona*.
- 7. Calyx not obviously 5-angled (8)
- 8(7). Capsules depressed-globose or globose, not at all ovoid or evidently thickened about the style bases, commonly about as wide as long or wider (9)
- 8. Capsules globose-ovoid, mostly more or less thickened about the style bases (13)
- 9(8). Corolla lobes half to three fourths as long as the tube; edges of the calyx lobes often more or less revolute9. *C. suaveolens*.
- 9. Corolla lobes about as long as the tube; edges of the calyx lobes not revolute (10)

¹⁵⁴ Adapted from Truman G. Yuncker in C. L. Lundell, Flora of Texas III:123-150. 1943.

- 10(9). Calyx with hornlike spurs 8. *C. Runyonii*.
10. Calyx lacking spurlike projections (11)
- 11(10). Calyx lobes overlapping at the base; withered corolla about the lower part of the smooth capsule 5. *C. campestris*.
11. Calyx lobes scarcely overlapping; withered corolla surrounding the capsule which is typically papillate about the top (12)
- 12(11). Calyx and pedicels not papillate 6. *C. glabrior* var. *glabrior*.
12. Calyx and pedicels papillate 7. *C. glabrior* var. *pubescens*.
- 13(8). Corolla lobes acute, with inflexed tips (14)
13. Corolla lobes obtuse (17)
- 14(13). Flowers commonly smooth; calyx lobes oval-ovate, obtuse; capsules mostly 1- or 2-seeded 10. *C. decipiens*.
14. Flowers fleshy, papillate; calyx lobes triangular-ovate to lanceolate, acute; capsules mostly 2- to 4-seeded (15)
- 15(14). Flowers mostly 4-parted; infrastamineal scales represented by wings that are shorter than the corolla tube 13. *C. Coryli*.
15. Flowers 5-parted; infrastamineal scales well-formed, reaching the filaments (16)
- 16(15). Calyx lobes triangular-ovate 11. *C. indecora* var. *indecora*.
16. Calyx lobes lanceolate 12. *C. indecora* var. *longisepala*.
- 17(13). Withered corolla about the top of the capsule 16. *C. Gronovii* var. *calyptrata*.
17. Withered corolla not at the top of the capsule (18)
- 18(17). Calyx lobes mostly about half as long as the corolla tube 14. *C. Gronovii* var. *Gronovii*.
18. Calyx lobes mostly about as long as the corolla tube ... 15. *C. Gronovii* var. *latiflora*.
- 19(3). Flowers pedicellate, loosely paniculate; sepals and bracts oval-orbicular-ovate 17. *C. cuspidata*.
19. Flowers sessile, in dense compact clusters (20)
- 20(19). Bracts and sepals oblong-lanceolate or oval, loose, more or less squarrose, commonly with recurved tips 20. *C. glomerata*.
20. Bracts closely appressed to the flowers, not squarrose or with curved tips (21)
- 21(20). Sepals and bracts acute 18. *C. squamata*.
21. Sepals and bracts obtuse 19. *C. compacta*.
- 22(2). Flowers 4-parted; infrastamineal scales and calyx not reaching the filaments; calyx papillate 23. *C. leptantha*.
22. Flowers 5-parted; infrastamineal scales mostly reaching the filaments; calyx not papillate, about equaling or surpassing the corolla tube (23)
- 23(22). Calyx lobes triangular-ovate, obtuse, commonly dorsally carinate; flowers subsessile or short-pedicellate 21. *C. applanata*.
23. Calyx lobes triangular-ovate-lanceolate, acute to acuminate; pedicels commonly as long as or longer than the flowers that are in loose umbellate cymes 22. *C. umbellata*.

1. *Cuscuta obtusiflora* H.B.K. var. *glandulosa* Engelm. Flowers 1.5-2 mm. long from base to corolla sinuses, 5-merous, commonly with numerous enlarged pellucid glandlike cells, subsessile in scattered moderately open glomerate-cymose clusters; calyx lobes nearly enclosing the corolla tube, commonly unequal (one smaller than the others), ovate, obtuse, scarcely overlapping at base; corolla lobes somewhat shorter than the tube, ovate

to ovate-oblong, obtuse to acutish, upright to spreading; scales about reaching the filaments, oblong, fringed about the top, sometimes bifid or truncated; styles stoutish and subulate, shorter than or about equaling the ovary; capsule depressed-globose, interstyler aperture large, the withered corolla remaining at the base. *C. glandulosa* (Engelm.) Small. Occasional throughout Tex. but most frequent in the s.e. section; also the Gulf States, W.I., Mex. and S.A.; most frequently on species of *Polygonum* but also on other plants as *Justicia americana*.

2. *Cuscuta Polygonorum* Engelm. SMARTWEED DODDER. Flowers 1-1.5 mm. long from base to corolla sinuses, mostly 3- or 4-merous, subsessile in compact glomerulate clusters; calyx lobes triangular-ovate, often unequal, not overlapping at base, as long as or longer than the corolla tube; corolla lobes triangular, acute, upright, as long as or longer than the tube; scales oblong, about reaching the filaments or commonly shorter, mostly bifid, the processes mostly few and near the top; styles shorter than the ovary, becoming subulate and divergent; capsule globose or obpyriform, commonly depressed, appearing cubical about the maturing seeds, interstyler aperture large and rhombic. From N.E. and Ont., w. and s.w. to Neb., Ark. and Tex. (*vide* Small); mostly on species of *Polygonum* but also on species of *Penthorum*, *Impatiens*, *Lycopus* and others.

3. *Cuscuta Cephalanthi* Engelm. BUTTON-BUSH DODDER. Flowers about 2 mm. long from base to corolla sinuses, 3- or 4-merous, rarely 5-merous, with numerous pellucid glandlike cells, sessile or subsessile in spicate or paniculately cymose clusters, frequently originating endogenously in the regions of the haustoria, the clusters at first open but soon becoming compact as the capsules mature; calyx shorter than the corolla tube, deeply divided, the ovate-oblong lobes obtuse and slightly overlapping at the base, the margins often minutely irregular; corolla lobes much shorter than the tube, ovate, obtuse, erect to spreading; scales narrowly oblong, about reaching the filaments, fringed with scattered processes; styles slender, about equal to or slightly longer than the ovary; capsule depressed-globose or globose, commonly only 1 or 2 seeds maturing, more or less lopsided when but one seed matures, the walls thin, capped by the withered corolla that is easily removed. From Me. and Va., w. to Wash. and Calif., less frequently s. to Mex., rare in n.-cen. Tex.; parasitic on a wide variety of woody and herbaceous hosts including species of *Salix*, *Boehmeria*, *Vicia*, *Justicia*, *Teucrium*, *Physostegia*, *Cephalanthus*, *Vernonia*, *Solidago*, *Aster* and *Sonchus*.

4. *Cuscuta pentagona* Engelm. Flowers 1-1.5 mm. long from base to corolla sinuses, the protruding capsules soon causing the flowers to appear larger, commonly with pellucid glandlike cells, with pedicels about as long as the flowers or commonly somewhat shorter, in loose cymose clusters; calyx mostly about as long as and loose about the corolla tube; calyx lobes broadly ovate, obtuse, commonly as broad as or broader than long, often unequal, widely overlapping at the sinuses to form 5 conspicuous angles; corolla lobes lanceolate, about as long as or slightly longer than the tube, spreading or reflexed, the acute tips inflexed; scales ovate-oblong, reaching the filaments, prominently fringed; styles slender, about equal to or slightly shorter than the ovary; capsule mostly more or less depressed-globose to somewhat ovoid, frequently longer than wide, the withered corolla remaining about the lower part. Frequent in the e. part of the U.S., w. to Okla., Tex., Colo., Mont. and Calif.; parasitic on species of *Justicia*, *Euphorbia*, *Ceanothus*, *Hibiscus*, *Tecoma*, *Solidago*, *Aster*, *Ambrosia*, *Anthemis*, *Artemisia* and many others.

5. *Cuscuta campestris* Yunck. FIELD DODDER. Flowers to about 2.5 mm. long from base to corolla sinuses, appearing much larger when in fruit, smooth or with scattered pellucid glandlike cells, with pedicels mostly shorter than the flowers, in glomerate-cymose clusters; calyx lobes about as long as the corolla tube, overlapping at the base but not markedly angled at the sinuses, ovate to oval-ovate, commonly as long as wide, obtuse; corolla lobes triangular to sublanceolate, about as long as the tube, spreading to reflexed, often granulate, the acute tips inflexed; scales reaching the filaments, ovate-oblong, abundantly fringed; style slender to slightly subulate, as long as or longer than the ovary; capsule depressed-globose, the withered corolla remaining about the lower half. *C. arvensis* Engelm. Distributed over the range of the genus; parasitic on a great variety of mostly herbaceous hosts including species of *Gilia*, *Justicia*, *Xanthium*, *Penthorum*, *Mirabilis*, *Ludwigia*, *Erigeron*, *Trifolium* and *Medicago*.

6. *Cuscuta glabrior* (Engelm.) Yunck. var. *glabrior*. Flowers about 2 mm. long from base to corolla sinuses, white or often reddish, commonly with numerous pellucid gland-

like cells, subsessile or mostly with pedicels no longer than the flowers or rarely longer, in compact or loose globular-cymose clusters; calyx lobes as long as or somewhat shorter than the corolla tube, ovate to oval-ovate, commonly not overlapping at base, the sinuses often obtusish; corolla lobes triangular to sublanceolate, smooth or commonly more or less papillate, about as long as the tube, spreading to reflexed, the acute to acuminate tips inflexed; scales reaching the filaments, oblong-spatulate, abundantly fringed; styles as long as or somewhat longer than the ovary that is more or less scabrous-papillate; capsule depressed-globose, the interstyler aperture large, often with numerous pellucid glandlike cells, scabrous-papillate at least above the middle, rarely smooth, sometimes easily breaking loose from the calyx and thus may be mistaken as circumscissile, surrounded by the withered corolla. Frequent in Tex., ranging from N.M. to Okla. and La., s. into n.e. Mex.; parasitic on a variety of mostly herbaceous hosts including species of *Amaranthus*, *Schrankia*, *Lespedeza*, *Dalea*, *Petalostemum*, *Croton*, *Oenothera*, *Gaura*, *Evolvulus*, *Convolvulus*, *Gilia*, *Verbena*, *Plantago*, *Aster*, *Ambrosia*, *Vicia*, *Bifora*, *Liatris*, *Phyllanthus*, *Lupinus*, *Asclepias*, *Justicia*, *Campsis*, *Condalia* and *Lesquerella*.

7. *Cuscuta glabrior* var. *pubescens* (Engelm.) Yunck. All parts of the flower (including ovary and capsule) and pedicel more or less densely papillate; otherwise similar to var. *glabrior*.

8. *Cuscuta Runyonii* Yunck. Stems smooth or often with scattered papillae near the inflorescences; flowers white or cream-white, drying yellow or reddish, 5-merous, mostly 2-3 mm. long from base to corolla sinuses, with numerous pellucid glandlike cells, with pedicels varying in length but commonly about equal to or somewhat longer than the flowers, in loose umbellate cymes of 2 to 5 or 6 flowers that are also somewhat umbellately arranged; bracts mostly 1-1.5 mm. long, ovate-oblong to triangular, acute, with a short obtuse saccate protuberance near the base; calyx lobes triangular to somewhat ovate, obtuse to acutish, not overlapping at base, about reaching the corolla sinuses or shorter, each with a prominent spurlike protuberance at the base and also frequently with a somewhat smaller one toward the apex; corolla lobes triangular-ovate to lanceolate, about as long as the tube or shorter, reflexed, acute to acuminate with the tips inflexed, papillate; scales prominent, oblong to subspatulate, reaching the filaments, profusely fimbriated; styles slender, equal to or longer than the ovary; capsule depressed-globose, smooth or papillate, enveloped by the withered corolla. Apparently endemic in the Rio Grande Plains and Valley of s. Tex.; host plants include species of *Dalea*, *Thamnosma*, *Spermolepis*, *Nama*, *Coldenia*, *Dyschoriste*, *Erigeron*, *Aster*, *Plantago*, *Melampodium*, *Parthenium* and *Xanthocephalum*.

9. *Cuscuta suaveolens* Sér. Flowers 2-4 mm. long from base to corolla sinuses, with numerous yellow pellucid glandlike cells, with pedicels commonly shorter than or infrequently longer than the flowers, in loose racemose- or paniculate-cymose clusters; calyx lobes shorter than the corolla tube, triangular-ovate, obtuse or acutish, scarcely overlapping at base, margins often revolute, sinuses obtusish; corolla lobes mostly half to three fourths as long as the tube, triangular-ovate, the upright acute tips inflexed; scales about reaching the filaments, ovate-oblong, fringed with medium-length processes; styles slender or slightly subulate, about equal to or sometimes longer than the ovary; capsule globose, mostly 2- to 4-seeded, enveloped by the withered corolla. A nat. of S.A. that has become widely distributed as a contaminant of seeds of *Medicago sativa*; parasitic on a variety of host plants but in the U.S. it is almost always found on *Medicago* and sometimes on *Lupinus*.

10. *Cuscuta decipiens* Yunck. Flowers about 2.5 mm. long from base to corolla sinuses, white or reddish, somewhat fleshy, often with pellucid glandlike cells; subsessile or with pedicels up to nearly as long as the flowers, in loose cymose clusters; calyx lobes shorter than the corolla tube, ovate to oval-ovate, scarcely overlapping at base, obtuse or rarely acutish; corolla lobes shorter than the tube, spreading or reflexed, oval- to triangular-ovate, sparingly serrulate toward the acute or infrequently obtusish inflexed tips; scales more or less spatulate, reaching the filaments or somewhat shorter, fringed with numerous processes; styles slender and mostly shorter than the ovary; capsule globose-ovoid, usually asymmetrical, somewhat umbonate, surrounded by the withered corolla. Rare in the Trans-Pecos, s. to Zac. and Coah.; parasitic on species of *Zinnia* and *Dyssodia*.

11. *Cuscuta indecora* Choisy var. *indecora*. PRETTY DODDER. Flowers variable in size, to 3 mm. long from base to corolla sinuses, white, fleshy, smooth or mostly granulate to

papillate-hispid, with pedicels commonly about as long as or shorter than the flowers or infrequently longer, in loose or rather dense paniculately cymose clusters; calyx lobes mostly shorter than the corolla tube, triangular-ovate, slightly overlapping at base, acute to obtusish; corolla lobes shorter than the tube, upright to spreading, triangular-ovate, inflexed at the acute tip; scales reaching the filaments, oblong to subspatulate, abundantly fringed; styles slender or slightly subulate, about as long as the ovary; capsule depressed-globose, thickened about the interstyler aperture, surrounded by the withered corolla which is eventually split by the enlarging capsule. Abundant in the s. states from Fla. to Calif., n. through the cen. states to Minn., Mich. and S.D., also in n. Mex., the W.I. and S.A.; parasitic on a wide range of herbaceous and woody hosts including species of *Eriogonum*, *Polygonum*, *Clematis*, *Cocculus*, *Fallugia*, *Acacia*, *Sesbania*, *Pithecellobium*, *Petalostemum*, *Prosopis*, *Rhus*, *Condalia*, *Malvastrum*, *Sapindus*, *Solidago*, *Datura*, *Adolphia*, *Cissus*, *Opuntia*, *Cephalanthus*, *Brickellia*, *Chilopsis*, *Vernonia*, *Aster*, *Baccharis*, *Iva*, *Pluchea*, *Ratibida*, *Borrchia*, *Helianthus*, *Lechea*, *Thelesperma*, *Campanula*, *Lesquerella*, *Gilia*, *Celtis*, *Coldenia*, *Eryngium* and *Carlowrightia*.

The size of the flowers, length of the pedicels and the proportionate size of the calyx vary greatly, sometimes even on the same specimen. Most of the flowers are more or less granulate because of the lenticular outer surface of the cells and occasional specimens are papillate-hispid.

12. *Cuscuta indecora* var. *longisepala* Yunck. This variety has the characteristics of the var. *indecora* with the exception of the calyx lobes that are lanceolate and mostly longer than the corolla tube.

13. *Cuscuta Coryli* Engelm. HAZEL DODDER. Flowers fleshy, papillate, 1.5-2 mm. long from base to corolla sinuses, mostly 4-merous, with pedicels shorter or longer than the flowers, in cymose-paniculate clusters, sometimes the flowers originate endogenously in the region of the haustoria and form dense glomerate clusters about the stem of the host; calyx lobes about as long as the corolla tube, triangular-ovate, acute, scarcely overlapping at base; corolla lobes about as long as the tube, triangular-ovate to lanceolate, upright, the acute tips inflexed; scales mostly reduced to toothed wings on either side of the filament attachment, rarely free and bifid or toothed; styles slightly subulate, mostly about as long as the ovary, becoming divergent in fruit; capsule globose, enveloped by the withered corolla the interstyler aperture rather large and thickened. From Mont. and Ariz. eastw.; parasitic on a large variety of herbaceous and woody hosts including species of *Salix*, *Carya*, *Rhus*, *Ceanothus*, *Lechea*, *Daucus*, *Callicarpa*, *Stachys*, *Symphoricarpos*, *Solidago*, *Aster* and *Helianthus*.

14. *Cuscuta Gronovii* R. & S. var. *Gronovii*. Flowers mostly 2-3 mm. long from base to corolla sinuses, rarely smaller or larger, commonly with few to many pellucid glandlike cells, with pedicels varying in length but mostly shorter than the flowers, rarely longer, in loose or dense paniculately cymose clusters, occasionally endogenously formed; calyx lobes commonly reaching to about the middle of the corolla tube, mostly oval-ovate, sometimes suborbicular or oblong, obtuse, overlapping at base, margins more or less uneven; corolla lobes shorter than the tube, mostly oval-ovate, obtuse, spreading; scales shorter than the corolla tube or reaching the filaments, oblong, deeply fringed about the upper part, more shallowly so towards the base and on the bridge; styles stoutish and sometimes somewhat subulate, mostly shorter than or about equal to the ovary, occasionally longer; capsule mostly globose-conic to obpyriform, surrounded by the withered corolla. The most common species of *Cuscuta* found throughout the cen. and n.e. states and the W.I., w. nearly to the Rocky Mts., commonly in low wet areas where it grows on a great variety of hosts including species of *Boehmeria*, *Helianthus*, *Myrica*, *Solidago*, *Salix*, *Hypericum* and *Lycopus*; occasionally reported as damaging ornamentals or other nonweedy hosts.

15. *Cuscuta Gronovii* var. *latiflora* Engelm. The flowers are commonly smaller than in var. *Gronovii*, the calyx lobes are more oblong-oval and less overlapping at the base and reach the corolla sinuses, the corolla tube is broadly campanulate with the throat wider than the tube which tapers towards the base and ordinarily is borne at the base of the maturing and thus protruding naked capsule.

16. *Cuscuta Gronovii* var. *calyprata* Engelm. In this variety the corolla tube is commonly somewhat longer than in var. *Gronovii* and with the lobes less than half as long as the tube, when mature the capsule carries the withered corolla about the top; otherwise similar to the var. *Gronovii*.

17. *Cuscuta cuspidata* Engelm. Flowers membranous in texture, about 3 mm. long from base to corolla sinuses, sessile or commonly pedicellate in loose paniculate clusters, the whole inflorescence more or less bracteate; calyx shorter than the corolla tube, of distinct or very slightly united segments, subtended by one or more ovate-orbicular obtuse to acutish sometimes cuspidate bracts, or these rarely lacking; calyx segments ovate-orbicular, obtuse to acutish and cuspidate, the margins commonly thin and serrulate, sometimes globular-thickened along the median line, broadly overlapping; corolla lobes oval-oblong to subovate, shorter than the funnellform tube, commonly more or less acute and somewhat cuspidate, occasional lobes serrate near apex, sometimes obtuse, commonly with a line of pellucid glandlike cells along the middle, spreading; scales shorter than the corolla tube, oblong, fringed with medium-length processes; styles slender, much longer than the ovary; capsule subglobose, with a thickened ridge or collar about the interstyler aperture, commonly with glandlike cells, enveloped at the top by the withered corolla. Through the cen. states from Ut. and Colo., e. to s.w. Ind.; parasitic on a number of different species of herbaceous hosts but seems to prefer members of the Compositae including species of *Ambrosia*, *Baccharis*, *Helianthus*, *Iva* and *Liatris*.

18. *Cuscuta squamata* Engelm. Flowers about 3 mm. long from base to corolla sinuses, sessile, in scattered few- to several-flowered glomerules, or these densely clustered about the host, subtended by 2 to several ovate acute often cuspidate serrulate closely appressed bracts that are mostly shorter than the calyx; calyx lobes distinct or nearly so, ovate, acute, often cuspidate, closely appressed and widely overlapping at base, commonly serrulate, with pellucid glandlike cells along the middle; corolla lobes ovate-lanceolate or slightly oblong, acute, sometimes cuspidate, shorter than the tube, spreading to reflexed, more or less glandular along the middle; scales about reaching the filaments, oblong, fringed with medium-length processes; styles slender, longer than the ovary; capsule globose to subconic, more or less umbonate, carrying the withered corolla about the top. Rare in the Trans-Pecos, Plains Country and Hardin Co. in s.e. Tex.; also s. N.M. and n. Mex.; parasitic usually on various weedy species of Compositae.

19. *Cuscuta compacta* Juss. Flowers often greenish, to 4.5 mm. long from base to corolla sinuses, sessile or rarely short-pedicellate, in few- to several-flowered scattered glomerules, or these commonly closely clustered about the host, frequently originating endogenously and forming a dense ropelike cluster about the stem of the host, subtended by 2 to several ovate-orbicular fleshy tightly appressed bracts; calyx deeply divided; calyx segments distinct or nearly so, broadly overlapping, fleshy, cupped, rounded, obtuse, tightly appressed about corolla, the margins fringed with short slender filamentous processes; corolla lobes spreading to reflexed, much shorter than the tube, oval-oblong, rounded, obtuse, sometimes fringed with short filamentous processes; scales reaching the filaments, fringed with long processes, small secondary scales often present on the bridge between the larger ones; styles mostly longer than the ovary; capsule globose-conic, upper part with glandlike cells and capped by the withered corolla, thickened at the top about the interstyler aperture. Extending from N.E. to Fla. and w. to Mo., Ark. and Tex.; parasitic on a wide range of herbaceous and woody hosts including species of *Carya*, *Alnus*, *Magnolia*, *Sassafras*, *Lindera*, *Rubus*, *Rosa*, *Rhus*, *Ilex*, *Acer*, *Vitis*, *Cissus*, *Clethra*, *Vaccinium*, *Tecoma*, *Cephalanthus*, *Lycopus*, *Myrica* and *Boehmeria*.

20. *Cuscuta glomerata* Choisy. Stems disappearing early from between the dense stramineous ropelike floral masses (to 5 cm. thick) that are wound tightly about the stem of the host; flowers 4-5 mm. long from base to corolla sinuses, commonly originating endogenously and breaking forth into 2 parallel rows on opposite sides of the stem, sessile, subtended and surrounded by numerous lanceolate scarious serrate or lacerate more or less cymbiform bracts with recurved or sometimes coiled acute tips; calyx segments distinct, about as long as the corolla tube, similar in shape to the bracts, serrate, acute or rather obtusish, the tips spreading but not recurved; corolla lobes much shorter than the cylindrical tube, spreading to reflexed, oblong-lanceolate, commonly acute to obtusish, occasionally mucronate, mostly with glandlike cells along the middle; scales about reaching the filaments, oblong, fringed about the upper part, more sparingly so along the sides; style slender and much longer than the ovary; capsule globose-umbonate or flask-shaped, with a prominent collar about the base of the styles, carrying the withered corolla at the top. Throughout the Prairie States from s.w. Mich. and Ind., s. to Miss. and

w. to the Dakotas, Neb., Kan., Okla. and Tex., s. to the Edwards Plateau; parasitic on numerous herbaceous and woody species from a wide range of genera but exhibiting some preference for weedy members of the Compositae including species of *Vernonia*, *Liatris*, *Solidago*, *Aster*, *Silphium*, *Ambrosia*, *Helianthus* and *Helenium*.

21. *Cuscuta applanata* Engelm. Flowers 1.5-2 mm. long from base to corolla sinuses, membranous or somewhat fleshy, commonly with pedicels shorter than the flowers, in dense glomerulate clusters, or these looser and paniculately cymose; bracts small, obtuse; calyx about as long as the corolla tube and commonly loose about it; calyx lobes broadly triangular-ovate, obtusish, overlapping at base, often irregularly keeled in the median part and below the sinuses down onto the pedicels or (in some specimens) the keel may be lacking; corolla lobes about as long as the tube, spreading, ovate-lanceolate, with slightly irregular margins, obtusish or acute; scales reaching the filaments, oblong, fringed; styles slender, often somewhat longer than the ovary; capsule depressed-globose, somewhat angled about the seeds, slightly thickened and raised about the interstyler aperture, readily circumscissile to leave the obcordate dissepiment in the persistent calyx, surrounded by the withered corolla. Rare in the Trans-Pecos; s.w. U.S. and Mex.; parasitic on various herbaceous hosts including species of *Boerhaavia*, *Chamaesaracha* and *Ambrosia*.

22. *Cuscuta umbellata* H.B.K. Flowers stramineous, smooth or infrequently slightly papillate, commonly with some pellucid glandlike cells, mostly 2-2.5 mm. long from base to corolla sinuses, rarely much longer, with pedicels varying in length from shorter than to much longer than the flowers, in dense or loose compound cymose clusters, the ultimate umbellate divisions of 3 to 7 flowers; calyx lobes scarcely overlapping, triangular-ovate to sublanceolate, acute to acuminate, smooth or slightly papillate, the margins even or sometimes irregular; scales reaching the filaments, oblong-subspatulate, fringed with medium-length processes; styles slender and longer than the ovary; capsule depressed-globose, with a thickened collar about the interstyler apertures, commonly easily circumscissile but some specimens tardily so, surrounded by the withered corolla. Incl. var. *reflexa* (Coul.) Yunck. Mainly in the Trans-Pecos and Rio Grande Plains; s. U.S., the W.I., Mex. and n. S.A.; parasitic on a wide range of mostly low herbaceous hosts including species of *Polygonum*, *Atriplex*, *Suaeda*, *Amaranthus*, *Tidestromia*, *Alternanthera*, *Boerhaavia*, *Sesuvium*, *Trianthema*, *Portulaca*, *Tribulus*, *Kallstroemia*, *Euphorbia* and *Siphonoglossa*.

23. *Cuscuta leptantha* Engelm. Flowers to about 2 mm. long from base to corolla sinuses, mostly 4-merous, with pedicels as long as or longer than the flowers, in loose umbellate clusters; calyx much shorter than the corolla tube, campanulate, somewhat fleshy and papillose; calyx lobes slightly or not at all overlapping at base, triangular-ovate, acute; corolla somewhat fleshy and papillose (at least in the lower part); corolla lobes spreading to reflexed, nearly as long as the tube, lanceolate, acute; scales reaching to about the middle of the corolla tube, oblong, sometimes truncated, fringed with short processes; styles slender, much longer than the ovary; capsule globose, slightly umbonate, 2- to 4-seeded, easily and regularly circumscissile, carrying the withered corolla about the top. From s. Tex. to N.M. and along the Gulf of Calif.; parasitic on low herbs, especially species of *Euphorbia*.

24. *Cuscuta exaltata* Engelm. Stems fleshy, to 3 mm. thick; flowers about 4 mm. long from base to corolla sinuses, sessile or subsessile in spicate-paniculate clusters, the parts thick and fleshy, each flower subtended by an oval-ovate obtuse bract; calyx nearly enclosing the corolla, deeply divided; calyx lobes ovate-orbicular, concave, broadly overlapping, rounded at apex; corolla-lobes oval-ovate to suborbicular, much shorter than the tube, overlapping at base, upright to spreading, the apex rounded; scales half to two thirds as long as the corolla tube, represented by 2 wings (one on either side of the filament attachment), toothed along the upper part but often these may be free at the top and dentate or emarginate; styles about as long as the ovary, mostly of equal length, partially or completely united but easily separating when teased; capsule globose-ovoid to conic, enlarging to 1 cm. in length, carrying the withered corolla at the top, regularly circumscissile. With the exception of one collection from e. Fla. apparently confined to Tex.; parasitic on woody hosts, including species of *Juglans*, *Quercus*, *Ulmus*, *Rhus*, *Vitis* and *Diospyros*.

FAM. 153. POLEMONIACEAE JUSS.¹⁵⁵

PHLOX FAMILY

Perennials, biennials, annuals or rarely subshrubs; leaves either all alternate or opposite, or opposite below and becoming alternate up the stem, undivided to pinnately compound or rarely palmately dissected or lobed, the margin entire to toothed; inflorescence of sparse cymes or glomerules in corymbose or paniculate disposition, sometimes a solitary flower; flowers regular or sometimes irregular; sepals 5, partly united into a herbaceous or scarious calyx; petals 5, convolute in bud, partly united into a rotate, campanulate, funnelform or salverform corolla; stamens 5, partly adnate to the corolla tube; carpels 3, superior, united up to the linear stigmas; fruit usually a trilocular capsule, dehiscent loculicidally; seeds one to many in each cell, rounded, angulate or rarely winged, in some species becoming viscid when wet.

About 300 species in 15 genera, mostly in North America.

1. Calyx wholly herbaceous and accrescent; leaves alternate, pinnately compound with broad entire leaflets1. *Polemonium*, p. 1262.
1. Calyx partly or mostly scarious; leaves not as above (2)
- 2(1). Calyx closely accompanied by multiple veiny bracts; leaves undivided, coarsely toothed, opposite below passing to alternate upward; corolla irregular5. *Loeselia*, p. 1267.
2. Calyx not closely accompanied by multiple bracts (3)
- 3(2). Leaves all alternate (4)
3. Leaves all opposite or opposite below and becoming alternate up the stem (6)
- 4(3). Bracts mostly subtending individual flowers; corolla often salverform, lacking a distinct expanded throat2. *Ipomopsis*, p. 1263.
4. Bracts mostly subtending flower groups; corolla usually with a distinct throat (5)
- 5(4). Leaf tip foliose or (if subacerose) the calyx not woolly3. *Gilia*, p. 1265.
5. Leaf tip acerose; calyx woolly4. *Eriastrum*, p. 1267.
- 6(3). Annuals; leaves palmately parted or undivided, the segments or blade narrowly linear6. *Linanthus*, p. 1267.
6. Perennials or annuals; leaves undivided, entire or essentially so, broadly elliptic-oblong to subulate7. *Phlox*, p. 1268.

1. POLEMONIUM L.

JACOB'S LADDER

About 40 species, mostly in the Northern Hemisphere.

1. *Polemonium pauciflorum* Wats. Perennial to 5 dm. tall, musky-glandular above, the stem sparsely to copiously branched; leaves alternate, to 15 cm. long, with basally expanded petiole and oblong pinnately compound blade; leaflets 11 to 21, the terminal confluent, to 25 mm. long and 6 mm. wide; flowers paired or solitary, projecting horizontally, the peduncle to 45 mm. long; sepals at anthesis about 15 mm. long, enlarging in fruit, united one third their length, tapering to a callous tip; corolla yellowish or greenish, often suffused with purple, funnelform, the tube to 3 cm. long and the limbs to 1 cm. long; stamens zygomorphic, about equaling the corolla tube, pilose at the short-adnate base; stigmas exceeding the anthers; seeds usually fusiform and angulate, several in each cell of capsule. *P. Hinckleyi* Standl. In wooded canyons of Davis Mts. in the Trans-Pecos, July-Aug.; also s. Ariz. and n. Chih.

Our plant has been segregated as subsp. *Hinckleyi* (Standl.) Wherry primarily on the basis of its thinner stem-pubescence and longer sepals than in subsp. *pauciflorum*.

¹⁵⁵ Adapted from E. T. Wherry in C. L. Lundell, *Flora of Texas* I:283-321. 1966.

2. IPOMOPSIS MICHX.

Perennials, biennials, annuals or subshrubs; leaves alternate, usually extending well up the stem, undivided or pinnately dissected or lobed, the tips firm and sharp; flowers often individually bracted, solitary or in sparse glomerules, grouped in stout or slender panicles; sepals sharp-tipped, partly united by scarious membranes; petals red, pink, lavender or white, partly united to form a usually salverform regular or slightly irregular corolla that lacks a definitely expanded throat; stamens usually adnate unevenly well up the corolla tube; seeds elongate and angulate or rarely ovoid, often waxy and becoming viscid when wet.

About 25 species, many of which are in southwestern United States.

- 1. Plants small annuals; corolla regular, lavender to white, the tube 6-8 mm. long (2)
- 1. Plants subshrubs, perennials, biennials or occasionally annuals; corolla varying widely in symmetry, size and color (3)
- 2(1). Leaves distributed more or less uniformly up the stem, asymmetrically dissected above the middle into few linear segments 9. *I. pumila*.
- 2. Leaves aggregated at stem base and tip, almost symmetrically cut above the middle into few lobes 10. *I. polycladon*.
- 3(1). Subshrub; flowers in glomerules at tip of branches, purple-blotched, pink or white; corolla tube 5-7 mm. long (4)
- 3. Herbaceous though firm-textured; inflorescence a leafy panicle; corolla tube 10-40 mm. long (5)
- 4(3). Plant 2.5-5 dm. tall; most leaves undivided 1. *I. Wrightii*.
- 4. Plant 1-2 dm. tall; most leaves dissected 2. *I. Havardii*.
- 5(3). Panicle stout; flowers paired or solitary at tip of branches, lavender to white (6)
- 5. Panicle long and slender; flowers in glomerules (7)
- 6(5). Corolla tube 25-40 mm. long, the lobes 8-12 mm. long 3. *I. longiflora*.
- 6. Corolla tube 15-25 mm. long, the lobes 5-7 mm. long .. 4. *I. laxiflora*.
- 7(5). Corolla purple to pink; basal rosette moderately developed 5. *I. Thurberi*.
- 7. Corolla red, yellow-mottled on face; basal rosette well-developed (8)
- 8(7). Leaf segments filiform; petal lobes blunt 8. *I. rubra*.
- 8. Leaf segments linear; petal lobes pointed (9)
- 9(8). Sepals united less than half their length of around 8 mm., the broadly subulate blade tapering uniformly 6. *I. aggregata*.
- 9. Sepals united over half their length of around 5 mm., the blade abruptly contracted to a subulate tip 7. *I. arizonica* subsp. *texana*.

1. *Ipomopsis Wrightii* (Gray) Gould. Subshrub to 5 dm. tall, the appressed-pilose stems bearing above the middle multiple simple branches; leaves undivided, linear, to 25 mm. long, sometimes with a few basal leaves sparsely pinnatifid; glomerules few-flowered, at branch tips, with large ciliate bracts; sepals 4-6 mm. long, united to about the middle, the blade ciliate and awned; corolla salverform, obscurely irregular, the tube 5-7 mm. long and the white to lavender lobes 3-4 mm. long; stamens adnate well up the tube, uneven, exerted, the filament curved; stigmas exceeding the anthers; seeds 3 or 4 in each cell, viscid when wet. *Gilia Wrightii* Gray, *Navarretia Wrightii* (Gray) O. Ktze. On dry rocky slopes in the Trans-Pecos, summer; a large variant also in Colo. and Ut.

2. *Ipomopsis Havardii* (Gray) V. Grant. Subshrub to 2 dm. tall and broad, villous-pubescent; leaves to 15 mm. long, 1- or 2-pinnately dissected above middle into few narrowly linear segments, passing to undivided above; sepals 5-7 mm. long, united to about the middle, the subulate blade awned; corolla salverform, irregular, the tube 6-8 mm. long and the purple-blotched or pink lobes 3-6 mm. long; stamens unevenly adnate

well up the tube, exerted, the filament curved; stigmas exceeding the anthers; seeds numerous, not affected when wet. *Loeselia Havardii* Gray, *Gilia Havardii* Gray, *Navarretia Havardii* (Gray) O. Ktze. On dry hillsides in the Trans-Pecos, Mar.-Oct.; endemic.

3. *Ipomopsis longiflora* (Torr.) V. Grant. Much-branched biennial or annual to 6 dm. tall, firm-textured and nearly glabrous; leaves distant, to 4 cm. long, dissected into 7 narrowly linear segments, passing to undivided above; flowers paired or solitary, the peduncle to 35 mm. long, often arising from the axil of a linear bract on leafy branches disposed in a stout panicle; calyx dotted with short-stalked glands; sepals 5-8 mm. long, united to well above the middle, the broad-subulate blade long-awned and pilose within; corolla salverform, with slender tube 2.5-4 cm. long; corolla lobes white or lavender, obtuse or apiculate, 8-12 mm. long; stamens adnate unevenly up the tube, 2 or 3 often exerted; stigmas somewhat exceeding the anthers; seeds several in each cell, angulate, viscid when wet. *Gilia longiflora* (Torr.) G. Don. On dry sandy or rocky soil in w. half of Tex., Mar.-Oct.; from Okla. and Tex., w. to s. S.D. and cen. Mex.

4. *Ipomopsis laxiflora* (Coult.) V. Grant. Resembling *I. longiflora* but more delicate with smaller parts; mostly less than 4 dm. tall with leaves at most 5-segmented and less than 3 cm. long; peduncle usually less than 15 mm. long; sepals 6 mm. long; corolla tube 25 mm. long and lobes about 5 mm. long. *Gilia Macombii* Gray var. *laxiflora* Coult. In similar habitats with similar range to *I. longiflora*.

5. *Ipomopsis Thurberi* (Gray) V. Grant. Biennial or short-lived perennial to 75 cm. tall, finely pubescent; leaves to 5 cm. long, dissected into 7 linear segments, passing to undivided above; flowers in glomerules in a long slender panicle; sepals about 7 mm. long, united to about the middle, the blade awn-tipped; corolla salverform, regular, the tube 25-35 mm. long and the purple lobes to 8 mm. long and 5 mm. wide; stamens unevenly long-exserted; styles pilose; stigmas exceeding the anthers; seeds several in each cell, viscid when wet. In Tex. known only from El Paso Co., summer; from w. Tex. to Ariz. and n. Mex.

6. *Ipomopsis aggregata* (Pursh) V. Grant. Coarse biennial with conspicuous basal rosette and firm simple stems to 2 m. tall, moderately glandular-pubescent; leaves numerous, to 5 cm. long, dissected into narrowly linear segments; inflorescence a long slender panicle of sparse glomerules; sepals 6-9 mm. long, united to below the middle, the broadly subulate blade tapering to a short awn; corolla bright-red, salverform, the tube 2-3 cm. long, the lobes 8-10 mm. long and acute; stamens unevenly adnate up the tube, sometimes with 1 or 2 exerted; stigmas exceeding the anthers; seeds many in each cell, angulate, viscid when wet. On dry rocky slopes in the Trans-Pecos, summer-fall; from B.C. to Calif., n. Mex. and w. Tex.

7. *Ipomopsis arizonica* (Greene) Wherry subsp. *texana* (Greene) Wherry. Similar to *I. aggregata* but the sepals are 4.5-6.5 mm. long and united to about or above the middle, with an abruptly contracted blade. *Gilia texana* (Greene) Woot. & Standl., *Ipomopsis aggregata* var. *texana* (Greene) Shinnery. Similar habitat, blooming season and distribution to *I. aggregata* in Tex.; from Colo. to e. Calif., w. Tex. and n. Mex.

8. *Ipomopsis rubra* (L.) Wherry. TEXAS PLUME, STANDING CYPRESS. Coarse biennial with noticeable basal rosette and simple stem to about 2 m. tall, sparsely pubescent, without glands; leaf segments filiform; sepals 8-9 mm. long, united to below the middle, the broadly subulate blade obscurely awned; corolla tube stout, 2-2.5 cm. long; corolla lobes about 9 mm. long and 5 mm. wide, somewhat obtuse to subacute; seed coat swelling but scarcely becoming viscid when wet. *Gilia rubra* (L.) Heller. In sun or partial shade in dry sandy or rocky ground in cen. and e. Tex., summer-fall; from Tex., e. to Fla. and n. to N.C.

This plant has some of the showiest flowers of any species of plant found in Texas.

9. *Ipomopsis pumila* (Nutt.) V. Grant. Finely pubescent annual to 2 dm. tall, branched from base; leaves to 3 cm. long, asymmetrically dissected above middle into 3 or 5 linear spine-tipped segments; flowers solitary or in sparse glomerules that are subtended by woolly-based leafy bracts; sepals 5-7 mm. long, united to the middle or above the middle, with a conspicuous awn-tip; corolla salverform, the tube 7-9 mm. long, the lavender or white lobes about 3 mm. long and 2 mm. wide; stamens adnate up to the tube summit, the free filament curved, short-exserted; stigmas exceeding the anthers; seeds few, viscid when wet. *Gilia pumila* Nutt. Among sparse shrubs in semiarid lands in w.-cen. and far w. Tex., spring; from w. Neb. and s. Wyo., s. to Ut., N.M. and Tex.

10. *Ipomopsis polycladon* (Torr.) V. Grant. A minutely glandular and sparsely villous spreading-branched annual to 1 dm. tall and 2 dm. broad; leaves mainly in a basal cluster but with a few reduced ones at stem nodes and tip, to 25 mm. long, divided above middle into few sharp-tipped segments; flowers in dense glomerules at branch tips, with 3-lobed bracts; sepals 5-6 mm. long, united to about the middle, short-awned; corolla salverform, the tube 3-6 mm. long, the lavender lobes 1-2 mm. long; stamens adnate to tube summit, barely exerted; stigmas equal to the anthers; seeds mostly 2 in each cell, fusiform, viscid when wet. *Gilia polycladon* Torr. Among sparse shrubs in semiarid lands in the Trans-Pecos, spring; from w. Colo. to Ut., s. to Tex. and Chih.

3. GILIA R. & P.

Perennials, biennials or annuals; leaves alternate, borne mainly below mid-stem, pinnately toothed or dissected, the segments herbaceous or rarely subaceroso; flowers in bracted glomerules, unevenly paired or solitary, terminating paniculately disposed branches; sepals partly united, separated and bordered by scarious membranes; petals violet-blue to lavender, often with yellow throat, partly united to a regular rotate to funnel-salverform corolla; stamens even to moderately uneven; seeds viscid when wet.

About 60 species in western North America and South America.

- 1. Corolla funnel-salverform, lavender; plant a delicate annual (2)
- 1. Corolla rotate-campanulate, violet-blue to lavender; plant perennial or (when annual or biennial) heavy-textured (3)
- 2(1). Flowers borne along branches; corolla 8-15 mm. long, the throat elongate; capsule longer than broad5. *G. flavocincta* subsp. *australis.*
- 2. Flowers borne mainly at branch tips; corolla 4-8 mm. long, the throat short; capsule broader than long6. *G. mexicana.*
- 3(1). Petiole of major leaves long and slender; leaf blade and its segments broad, incised-toothed; duration various1. *G. incisa.*
- 3. Petiole of major leaves short and winged or none, or the leaf segments narrow (4)
- 4(3). Sepals united for only one fourth to one third their length, 4-6 mm. long; corolla inconspicuous; leaves pinnatifid into narrow segments2. *G. Stewartii.*
- 4. Sepals united for one third to two thirds their length; corolla showy (5)
- 5(4). Basal leaves persistent, obovate, pinnatifid into about 6 pairs of broad coarse-toothed segments4. *G. ludens.*
- 5. Basal leaves ranging from persistent to short-lived, variously pinnatifid into coarse to fine segments (6)
- 6(5). Sepals 7-9 mm. long; branches widely spreading; herbage glabrescent to moderately glandular; segments of many leaves coarse; corolla 15-25 mm. across3a. *G. rigidula* subsp. *insignis.*
- 6. Sepals 5-7 mm. long; branches moderately spreading to congested; herbage copiously glandular; segments of upper leaves fine; corolla 8-15 mm. across (7)
- 7(6). Segments of lower leaves few, broad and flat, the upper ones subaceroso3b. *G. rigidula* subsp. *rigidula.*
- 7. Segments of lower leaves (like the upper ones) few to numerous, all subaceroso3c. *G. rigidula* subsp. *acerosa.*

1. *Gilia incisa* Benth. A minutely glandular firm-textured perennial, biennial or annual to 5 dm. tall; leaves to 6 cm. long and 15 mm. wide, long-petioled; blade unsymmetrically incised, often pinnate at base and conspicuously reduced up the stems; flowers solitary or unevenly paired on peduncles to 35 mm. long; sepals about 4 mm. long, united to about or below the middle, the scarious membranes running extended up as blade

margins; corolla tube 3-4 mm. long, the lavender to whitish lobes about 8 mm. long and spreading to a subrotate limb 10 mm. across; stamens subuniform, short-exserted; stigmas exceeding the anthers; seeds few in each cell, narrowly winged. *G. Lindheimeriana* Scheele. On gravelly or sandy slopes in the s.w. half of Tex., spring; Tex. and N.M. s. to Hgo.

2. *Gilia Stewartii* I. M. Johnst. Woody-based minutely glandular biennial or short-lived perennial to 3 dm. tall; basal leaves to 5 cm. long, bipinnately dissected, forming an early-withering rosette; stem leaves pinnately dissected into mostly linear segments, noticeably reduced upward; flowers paired or solitary on peduncles to 3 cm. long; sepals 4-5 mm. long, united to well below the middle, the scarios membranes extending up as narrow blade margins; corolla 8-10 mm. long, lavender; petals only shortly united, their blades 2.5-5 mm. wide; stamens short-exserted; stigmas exceeding the anthers; seeds numerous, minute. On rocky open slopes in the Trans-Pecos, spring; also Mex.

3a. *Gilia rigidula* Benth. subsp. *insignis* Brand. Glabrescent spreading-branched woody-based perennial to 4 dm. tall and broad; lower leaves numerous, to 4 cm. long and 15 mm. wide, obscurely petioled; blade asymmetrically dissected into few coarsely dentate segments, rapidly reduced above; flowers in sparse glomerules or solitary on peduncles to 4 cm. long; sepals 7-9 mm. long, with distinct awn-tip, united to about the middle or slightly below the middle, the scarios membranes extended up as broad blade margins; corolla 18-25 mm. long, opening in sunlight to a rotate violet-blue limb with yellow eye; stamens 8-10 mm. long, the filaments short-adnate, the large anthers sagittate; stigmas exceeding the anthers; seeds numerous, minute. *G. insignis* (Brand) Cory & Parks. On dry rocky slopes, rare in the Trans-Pecos, spring; also Coah.

3b. *Gilia rigidula* subsp. *rigidula*. A fine-glandular spreading-branched perennial to 25 cm. tall; lower leaves to 35 mm. long, unsymmetrically dissected into few oblong often dentate segments that pass to linear or filiform segments above; flowers laxly glomerate to solitary, on peduncles to 25 mm. long; sepals 5-7 mm. long, obscurely awned, united to about or below the middle, the scarios membranes running up as blade margins; corolla 8-15 mm. long, opening in sunlight to a rotate violet-blue limb with yellow eye; stamens 5-7 mm. long, the filaments short-adnate and the anthers sagittate; stigmas exceeding anthers; seeds small. In dry rocky and sandy land in w. half of Tex., blooming in spring and sometimes again in fall; from Tex. to Colo., Ariz. and s. to Dgo.

3c. *Gilia rigidula* subsp. *acerosa* (Gray) Wherry. This entity differs from subsp. *rigidula* in its more compact habit, being mostly under 1 dm. tall, the leaves to 2 cm. long and with the segments subulate and rather sharp-tipped. *G. acerosa* (Gray) Britt. Most frequent in n.w. Tex.; also w. Neb. to Ariz. and Son.

4. *Gilia ludens* Shinnars. Resembling *G. rigidula* in many respects but differs from that species primarily in developing a persistent rosette of obovate leaves that are pinatifid into about 6 pairs of broad coarse-toothed segments. Rio Grande Plains in Duval, Jim Wells and Webb cos., spring; endemic.

5. *Gilia flavocincta* A. Nels. subsp. *australis* (A. & V. Grant) Day & V. Grant. Winter annual with lax basal rosette, to 3 dm. tall, the herbage flocculent-hairy toward base and passing upward to sparse-glandular or glabrous; stems few or solitary; leaves extending to above mid-stem, to 3 cm. long, 1- or 2-pinnately lobed, the length of the linear lobes over 3 times the rachis width; inflorescence elongate; flowers in unsymmetrical 2- to 4-flowered glomerules on glabrous or sparse-glandular pedicels to 14 mm. long; sepals 3-4.5 mm. long, united to above the middle, the tip acute; corolla funnel-salverform, lavender with yellow throat, the short tube plus the long throat 8-15 mm. long and the lobes 3-6 mm. long; stamens subequal, short-exserted; stigmas near anthers; capsule broadly ovoid. *G. ophthalmoides* Brand subsp. *australis* A. & V. Grant. In dry sandy land in extreme w. Tex., spring; from Tex. across N.M. into Ariz.

6. *Gilia mexicana* A. & V. Grant. Habit similar to *G. flavocincta* but differing in its well-developed compact rosette, stems often multiple, inflorescence chiefly terminal, corolla relatively small (4.5-7.5 mm. long) with the tube and part of the throat included in calyx, and the capsule narrowly ovoid. Rare in w. tip of Tex., spring; Tex., N.M., Ariz. and Chih.

4. ERIASTRUM WOOT. & STANDL.

About 15 species in western North America.

1. *Eriastrum diffusum* (Gray) Mason. Spreading-branched annual to 1 dm. tall and 15 cm. broad, glabrous except at the base and around the inflorescence; leaves few, alternate, to 35 mm. long, the lower leaves asymmetrically dissected into 3 filiform segments, the upper leaves undivided; glomerules woolly, exceeded by 3- to 5-parted bracts; sepals 5-6 mm. long, uneven in length, united to about the middle, with sharp awn-tip; corolla regular to irregular, salverform, the tube expanded upward into a throat, the tube about 6 mm. long, the throat 1-2 mm. long, the lavender to white lobes 2-3 mm. long; anthers and stigmas reaching the tube orifice; seeds few to one in each cell, ovoid, brown, often viscid when wet. On dry slopes in the Trans-Pecos, spring; from w. Tex. to s. Calif. and n. Mex.

Eriastrum filifolium (Nutt.) Woot. & Standl. (*Gilia filifolia* Nutt.), of the California coast, has been mistakenly reported from Texas.

5. LOESELIA L.

Subshrubs, perennials or annuals with pubescent herbage; leaves opposite below and either nearly so throughout or passing to alternate upward, undivided, ovate to oblong or lanceolate, serrate to dentate; flowers in lax glomerules or solitary, axillary; calyx usually scarious, accompanied by toothed veiny bracts; corolla funnelform to salverform, irregular; corolla lobes purple, red, pink or white; stamens irregular, adnate well up the corolla tube, exserted; stigmas usually exceeding the anthers; seeds viscid when wet.

About 10 species from southwestern United States to South America.

1. Corolla pink, about 15 mm. long; bracts ovate 1. *L. scariosa*.
1. Corolla red, about 25 mm. long; bracts elliptic 2. *L. mexicana*.

1. *Loeselia scariosa* (Mart. & Gal.) Walp. Branched subshrub to 5 dm. tall; leaves to 25 mm. long and 1 cm. wide, sharply dentate with aristate teeth; inflorescence 1- to 3-flowered; bracts ovate, imbricated, aristate-toothed, green- to bronzy-reticulate, the areoles scarious; sepals coarsely toothed; corolla tube about 1 cm. long, pubescent on outer surface; corolla lobes pink with a white base, about 4 mm. long and 3 mm. wide; filaments adnate to above mid-tube, pilose. *L. Greggii* Wats. Rare on rocky slopes in the Trans-Pecos, fall; also in Mex. s. to Pue.

2. *Loeselia mexicana* (Lam.) Brand. Similar to *L. scariosa* but differing in leaves to 35 mm. long, the flowers solitary, corolla red and the tube about 2 cm. long with lobes 8 mm. long. Rare in the s. Trans-Pecos; also over much of Mex.

6. LINANTHUS BENTH.

About 35 species in western North America.

1. *Linanthus Bigelovii* (Gray) Greene. Nearly glabrous annual to 3 dm. tall; leaves opposite, mostly linear and undivided but a few lower ones sometimes palmately 3-parted, to 3 cm. long; flowers solitary or paired, subtended by a pubescent linear bract in stem forks; sepals somewhat uneven, about 1 cm. long, united nearly to tip by conspicuous broad membranes; corolla funnel-salverform, about 15 mm. long, white with bronze stripes, vespertine; stamens uniform, shortly adnate, the elongate anthers deep-included; styles less than half united; seeds angulate, swelling when wet. *Gilia Bigelovii* Gray. Among scattered shrubs on dry rocky slopes in far w. Tex., spring; from Tex. to Calif.

Linanthus aureus (Nutt.) Greene of New Mexico westward has been reported from Texas but no material has been seen from the state. It may occur in the Trans-Pecos, and may be distinguished from *L. Bigelovii* by its diffusely branched stem, palmately parted leaves with linear to oblanceolate divisions mostly less than 1 cm. long, diurnal flowers with turbinate calyx and broadly funnelform corolla with a usually bright-yellow limb.

7. PHLOX L. PHLOX

Subshrubs, perennials or annuals, the herbage pubescent with glandular or glandless hairs or rarely glabrous; leaves all opposite or opposite below passing to alternate upward, undivided, broadly elliptic to ovate or subulate, entire or nearly so; flowers in variously grouped glomerules or cymes or solitary; sepals united for three eighths to three fourths their length by scarious membranes, the lobes often pubescent within and cuspidate to aristate; petals united to form a salverform regular corolla, the lobes obtuse to apiculate or notched, purple, red, pink, lavender, white or rarely yellow; stamens markedly uneven; seeds one or rarely several in each cell, ellipsoidal, unchanged when wet.

A genus of 50 or more species in America. When the ranges of annual Phloxes overlap hybridization may occur. In our area *P. cuspidata* and *P. Drummondii* frequently form hybrid swarms that are readily recognized in the field.

- 1. Styles exceeding the sepals, the united part elongate . . . 12. *P. carolina* subsp. *angusta*.
- 1. Styles shorter than sepals, the united part only slightly or not exceeding the stigmas (2)
- 2(1). Habit subshrubby; petal lobes notched (3)
- 2. Habit perennial or annual (4)
- 3(2). Petal lobe about as broad as long; leaves mostly linear 1. *P. oklahomensis*.
- 3. Petal lobe longer than broad; leaves mostly subulate . . . 2. *P. nivalis*.
- 4(2). Corolla tube constricted at orifice; cells multiovulate (5)
- 4. Corolla tube not constricted; cells usually uniovulate (8)
- 5(4). Annual; most leaves alternate 6. *P. Roemeriana*.
- 5. Perennial; most leaves opposite (6)
- 6(5). Pubescence glandless; calyx membranes subcarinate; leaves narrowly linear 5. *P. triovulata*.
- 6. Pubescence mostly glandular; calyx membranes flat or wrinkly (7)
- 7(6). Nodes few; leaves narrowly to broadly linear, some over 5 cm. long 3. *P. mesoleuca*.
- 7. Nodes numerous; leaves narrowly elliptic to lanceolate, none over 4.5 cm. long 4. *P. nana*.
- 8(4). Perennial; leaves mostly opposite (9)
- 8. Annual; leaves opposite below passing to alternate upward (10)
- 9(8). Leaves relatively broad; sepals barely awned 7. *P. divaricata* subsp. *Laphamii*.
- 9. Leaves relatively narrow; sepals definitely awned 8. *P. pilosa*.
- 10(8). Plant delicate with relatively fine pubescence and small parts; petal lobes mostly less than 7 mm. wide 11. *P. cuspidata*.
- 10. Plant robust with relatively coarse pubescence and large parts; petal lobes mostly over 7 mm. wide (11)
- 11(10). Major leaves less than 10 times as long as broad; corolla tube usually more than 1.4 cm. long 9. *P. Drummondii*.
- 11. Major leaves more than 10 times as long as broad; corolla tube 1-1.4 cm. long 10. *P. glabriflora*.

1. *Phlox oklahomensis* Wherry. Spreading subshrubby perennial to 2 dm. tall and broad; leaves linear to lanceolate, subevergreen, ciliate and the upper pilose, to 6 cm. long and 5 mm. wide; the herbage copiously pubescent with hairs varying from fine-glandular to glandless flowers in sparse cymes; sepals 7-10 mm. long, united to about the middle, the blades broad-subulate and cuspidate, the membranes flat to somewhat plicate; corolla tube

8-12 mm. long; corolla lobes lavender, pink or white, sometimes with paired striae at base of lobe, obovate, 8-10 mm. long and broad, with a terminal notch to 4 mm. deep; styles 2-3 mm. long, united to about the middle; ovules and seeds often 2 in each cell. *Phlox bifida* Beck var. *induta* Shinnars. In sandy woods in n.e. Dallas Co., spring; from s. Kan. to n.w. Okla. and s. to Tex.

2. *Phlox nivalis* Lodd. subsp. *texasensis* Lundell. Subshrub with long decumbent persistent leafy shoots and erect deciduous flowering shoots to 3 dm. tall; leaves on sterile shoots subulate and on fertile shoots short-lanceolate and to 25 mm. long, the herbage pubescent; hairs fine-glandular to glandless; flowers mostly 3 to 6 in cymes; sepals 6-10 mm. long, cuspidate, united to about the middle, the membrane flat or wrinkly; corolla tube 11-17 mm. long; corolla lobes to 12 mm. long and 7 mm. wide, shallowly notched or rarely entire; styles 3-4 mm. long, united for less than half their length; ovule and seed usually solitary. *P. texensis* (Lundell) Lundell. In open grassy pinelands in s.e. Tex., spring; endemic.

3. *Phlox mesoleuca* Greene. Moderately glandular-pubescent perennial varying markedly in stature and leaf-size from year to year in relation to climatic conditions, to about 6 dm. tall, with about 5 nodes below the inflorescence; major leaves narrowly to broadly linear, to 9 cm. long and 5 cm. wide; flowers in sparse cymes, the pedicels to 45 mm. long; sepals 13-18 mm. long, united to about the middle, the membranes flat or wrinkly; corolla tube 12-18 mm. long, constricted at orifice, sparsely pilose to glabrous; corolla lobes 11-14 mm. long and to 1 cm. wide, entire or erose, purple to pink, white or rarely pale-yellow, often with a conspicuous white eye; styles 2-4 mm. long, less than half united; ovules often 2 or 3 in each cell. On rocky slopes in the Trans-Pecos, blooming throughout its growing season; from Tex. to e. Ariz. and n. Mex.

4. *Phlox nana* Nutt. Apparently derived from *P. mesoleuca* but differs in the copiously glandular herbage, less than 3 dm. tall with 6 to 12 close-set nodes; major leaves narrowly elliptic to lanceolate and to 45 mm. long and 5 mm. wide; pedicels rarely over 15 mm. long. It has about the same range and occurs in similar habitats as *P. mesoleuca*.

5. *Phlox triovulata* Torr. Apparently derived from *P. mesoleuca* but differs in having pubescence of long glandless hairs, the calyx membranes often plicate-carinate. It has the same range and occurs in similar habitats as *P. mesoleuca*.

6. *Phlox Roemeriana* Scheele. GOLD-EYE PHLOX. Showy winter annual to 35 cm. tall; leaves oblanceolate and opposite below but passing upward to lanceolate and alternate, eglandular-pubescent and ciliate, the largest to 5 cm. long and 1 cm. wide; flowers in asymmetric cymes, the herbage coarsely eglandular-pilose; pedicels to 35 mm. long; sepals 11-17 mm. long, united to below the middle, the lobes linear with obscure costa and membranes flat; corolla tube constricted at orifice, glabrous, 9-13 mm. long, the apiculate lobes averaging 14 mm. long and 11 mm. wide, purple, pink or rarely white with a conspicuous yellow eye; stamens included; styles 1.5-2 mm. long, united to about or below the middle, the stigmas below the anthers; seeds 3 to 5 in each cell. On dry rocky slopes and limestone barrens on the Edwards Plateau and adj. High Plains of Tex., spring; endemic.

7. *Phlox divaricata* L. subsp. *Laphamii* (Wood) Wherry. Perennial with subevergreen decumbent sterile shoots, sending up flowering shoots to 45 cm. tall, with about 6 well-spaced nodes; sterile shoot-leaves elliptic, to 5 cm. long and 25 mm. wide; fertile shoot-leaves broadly to narrowly lanceolate, smaller; inflorescence a compound cyme, its herbage minutely glandular; sepals 7-11 mm. long, united to about or below the middle, the lobes barely awned; corolla tube 12-18 mm. long, glabrous; corolla lobes lavender to white, averaging 13 mm. long and 8 mm. wide, the tip obtuse or apiculate but never notched; stamens deep in tube; styles 1.5-3 mm. long, about half-united, the stigmas adjacent to some anthers. Incl. var. *Laphamii* Wood. In humus-rich woodland soil along the e. Tex. border, spring; from e. S.D. to Wisc., Tex. to w. Fla.

8. *Phlox pilosa* L. Herbaceous perennial, in our region to 6 dm. tall and with 7 to 15 nodes, the occasional sterile shoots erect; leaves linear, passing upwards to lanceolate, to 12.5 cm. long near mid-stem and to 1 cm. broad near inflorescence base; flowers in small cymes aggregated into an ample panicle; longest pedicels to 2 cm. long; sepals 8-15 mm. long, united to about or below the middle, the lobes with a terminal awn to 3 mm. long; corolla tube 1-2 cm. long, varying from pubescent with glandular or eglandular hairs to

glabrous; corolla lobes purple, pink, lavender or white, 8-16 mm. long, obtuse to apiculate; styles 1.5-4 mm. long, about half-united, the stigmas below the anthers; cells normally uniovulate. In various habitats in e. to s.w. Tex., spring.

This species is markedly variable and is here divided into several taxa based on the following key characters.

1. Pubescence copious, glandular at least upward (2)
1. Pubescence sparse or obsolete (4)
- 2(1). Sepals subulate with the awn 1.5-3 mm. long8a. subsp. *pilosa*.
2. Sepals linear-subulate with the awn 1-2 mm. long (3)
- 3(2). Stem tending to be simple and moderately glandular8b. subsp. *latisejala*.
3. Stem tending to be branched and copiously glandular8c. subsp. *riparia*.
- 4(1). Hairs fine, glandular upward; sepal awn averaging 2 mm. long; corolla relatively small, the tube averaging 12 mm. long and the lobes 10 mm. long8d. subsp. *detonsa*.
4. Hairs coarse, eglandular; sepal awn averaging 1 mm. long; corolla relatively large, the tube averaging 17 mm. long and the lobes 12 mm. long8e. subsp. *pulcherrima*.

8a. *Phlox pilosa* subsp. *pilosa*. Herbage glandular, at least upward; major leaves 4-8 cm. long and 3-9 mm. wide; sepals 8-12 mm. long, the lobes subulate with an awn 1.5-3 mm. long; corolla tube 1-1.6 cm. long, varying from pubescent to glabrous without correlation with other characters. In the e. third of Tex. (Harris, Austin, Burnet and Williamson cos.); from Wisc. to Conn., s. to Fla. and Tex.

8b. *Phlox pilosa* subsp. *latisejala* Wherry. Stem pilose, to 45 cm. tall, the upper herbage glandular; major leaves to 6 cm. long and 8 mm. wide; sepals 8-12 mm. long, with a 1-2 mm. terminal awn, the blade linear-subulate and foliaceous with obscure costa and plicate membranes; corolla tube 11-17 mm. long, pilose; corolla lobes 1-1.2 mm. long; styles 3-4 mm. long, about half united. *P. pilosa* var. *aspera* (E. Nels.) Wherry. In open woods on dry slopes and less commonly in grassland, often over calcareous rocks, on and near the Edwards Plateau; endemic.

8c. *Phlox pilosa* subsp. *riparia* Wherry. Creeping woody rhizome well-developed, producing multiple erect or ascending often branched stems to 3 dm. tall with often crowded nodes, densely pubescent with many hairs glandular; leaves opposite and linear below, passing to lanceolate and alternate upward, the major ones to 45 mm. long and 8 mm. wide; inflorescence compact; sepals linear-subulate, the awn 1-2 mm. long and membranes somewhat plicate-carinate; corolla tube 1-1.5 cm. long, often glandular-pubescent. *P. villosissima* (Gray) Whiteh. On gravel deposits along streams and on talus slopes on and near the Edwards Plateau; endemic.

8d. *Phlox pilosa* subsp. *detonsa* (Gray) Wherry. Inflorescence-herbage sparsely glandular-pubescent passing to glabrous; stem and all except the uppermost leaves glabrous; measurements as in subsp. *pilosa*. In woods and thickets in e. Tex.; also e. to Ga. and Fla.

8e. *Phlox pilosa* subsp. *pulcherrima* Lundell. Pubescence of long coarse eglandular hairs, often sparse or even obsolete; major leaves to 12.5 cm. long; sepal awn averaging 1 mm. long. In grasslands and open pinelands in e. Tex.; from Tex. to La. and n. to s.w. Ind.

9. *Phlox Drummondii* Hook. Pubescent annual varying with environment from 1 to 5 dm. tall and from simple to branched; leaves opposite, subpetiolate and relatively narrow at 3 to 5 nodes, passing to alternate, sessile or clasping and broader upward; flowers in asymmetric glomerules of 2 to 6, grouped in a somewhat spiral inflorescence; sepals 7-12 mm. long, united for one third their length; corolla tube 1-2 cm. long, pubescent or exceptionally glabrous; styles 2-3 mm. long, united to about or below the middle, the stigmas below anthers; ovules normally solitary in the cells. In grasslands and open woodlands in neutral to moderately acid sandy soils in e. Tex., rare westw. and n.w., spring.

This species is highly variable and is here divided into several taxa based on the following key characters.

1. Stems relatively stout, tall and branched; leaves short and broad; corolla-hue varying markedly within colonies; introduced cultivars9c. var. *peregrina*.
1. Stems not markedly stout, tall or branched; corolla-hue varying little within colonies (except in manifest hybrids); native plants (2)
- 2(1). Corolla-hue bright-red, with dark-red eye-ring or star, the pigment persistent; corolla tube averaging 16 mm. long9b. subsp. *wilcoxiana*.
2. Corolla-hue purple, the pigment fugacious (3)
- 3(2). Eye pale with at most a narrow-rayed purple star; range northern (4)
3. Eye well-filled by a dark-red star or ring; range southern (5)
- 4(3). Herbage sparsely or not glandular; major leaves 4 to 5 times as long as wide; corolla tube 13-15 mm. long9d. subsp. *Mcallisteri*.
4. Herbage copiously glandular; major leaves 6 to 7 times as long as wide; corolla tube 18-22 mm. long9e. subsp. *Johnstonii*.
- 5(3). Corolla tube 12-16 mm. long; major leaves about 7 times as long as wide9a. subsp. *Drummondii*.
5. Corolla tube mostly 14-19 mm. long, rarely shorter; major leaves about 10 times as long as wide9f. subsp. *Tharpia*.

9a. *Phlox Drummondii* subsp. *Drummondii*. Major leaves 5 to 10 (averaging 7) times as long as wide; sepals 7-10 (averaging 8.5) mm. long; corolla tube pilose, 12-16 mm. long; corolla-hue purple, the eye nearly filled by a dark-red ring or star. In s.-cen. Tex., s. of a line connecting Guadalupe and Brazos cos., extending from the former down to San Patricio-Jackson, and from the latter to Austin-Harris cos.

9b. *Phlox Drummondii* subsp. *wilcoxiana* (Bogusch) Wherry. Major leaves 5 to 10 (averaging 7) times as long as wide; sepals 8-11 mm. long; corolla tube pilose, 15-17 mm. long; corolla-hue intense red, the eye filled with a dark-red ring or star. Incl. var. *wilcoxiana* (Bogusch) Whiteh., *P. Goldsmithii* Whiteh. Nat. in an area bounded by lines connecting Comal, Milam, Jackson and Goliad cos.

9c. *Phlox Drummondii* var. *peregrina* Shinnars. Stem tending to be stouter, taller and more branched than the above two subspecies that are supposed to have produced var. *peregrina* through hybridization; major leaves about 5 times as long as broad; corolla tube 15 mm. long; corolla-hue highly variable, from red to pink, purple, violet, lavender, white and even pale-yellow, with occasional monstrosities. Escaped from gardens and planted for roadside beautification in many parts of Tex.; escaped in many warm-temp. regions throughout the world.

9d. *Phlox Drummondii* subsp. *Mcallisteri* (Whiteh.) Wherry. Herbage not glandular or sparsely so; many leaves 4 to 5 times as long as wide; pedicels to 15 mm. long; sepals 8-11 mm. long; corolla tube 13-15 mm. long; corolla-hue light purple, with pale eye marked by a slender-rayed purple star. Incl. var. *Mcallisteri* (Whiteh.) Shinnars. Mainly in n.e. Tex., w. to Wichita Co. and s. to Leon Co.

9e. *Phlox Drummondii* subsp. *Johnstonii* (Wherry) Wherry. Stem branching; herbage pubescent throughout, with many of the hairs gland-tipped; leaves to 6 cm. long, with many 6 to 7 times as long as wide; sepals 8-10 mm. long; corolla tube slender, 18-22 mm. long, glandular-pilose; corolla-hue pink, with faintly striate pale eye. *P. Johnstonii* Wherry. Endemic in sandy open soil in a small area in n.w. Tex.

9f. *Phlox Drummondii* subsp. *Tharpia* (Whiteh.) Wherry. Stem simple or sparingly branched; leaves narrowly oblanceolate passing to linear-elliptic, the major ones averaging 10 times as long as wide; corolla tube to 2 cm. long; corolla-hue purple, with red eye-star. *P. Tharpia* Whiteh. Endemic in s.w. Tex. from Maverick and Dimmit e. to Bexar cos.

10. *Phlox glabriflora* (Brand) Whiteh. RIO GRANDE PHLOX. Villous-pubescent low annual, with multiple decumbent basal branches; leaves opposite at 4 or 5 nodes, passing to alternate upward, the major leaves ribbonlike, to 8 cm. long and mostly less than one tenth as wide; flowers in sparse asymmetric glomerules, the pedicels to 2 cm. long; sepals 7-12 mm. long, united for slightly less than half their length, tipped with an awn 0.5-1 mm. long; corolla tube 9-14 mm. long; corolla-hue light-purple to pink, with pale eye, at most faintly striate. Along the Gulf Coast and the lower Rio Grande Valley, extending inland to Atascosa and Duval cos.

The following two taxa are known.

1. Corolla tube glabrous; range Duval and Jim Hogg to Kleberg and Cameron cos.10a. subsp. *glabriflora*
1. Corolla tube pilose; range (with the preceding) Webb and Duval to Kenedy and Hidalgo, and isolated Atascosa to Aransas and Calhoun cos. [*P. Drummondii* var. *littoralis* Cory, *P. littoralis* (Cory) Whiteh., *P. Drummondii* subsp. *glabriflora* var. *littoralis* (Cory) Erbe & B. L. Turner]10b. subsp. *littoralis* (Cory) Wherry.

11. *Phlox cuspidata* Scheele. Delicate sparsely pubescent annual, varying with environment from 5 to 55 cm. tall, simple to branched; leaves opposite and oblanceolate at 4 to 6 nodes, passing to alternate and elliptic to linear upward, to 35 mm. long and 8 mm. wide; flowers in sparse asymmetric glomerules in a somewhat spiral cyme; pedicels to 6 mm. long; sepals finely glandular, 7-10 mm. long, one third to one half united, tipped with an awn 1-1.5 mm. long; corolla tube 8-15 mm. long, pilose with some hairs glandular; limb purple to pink with faintly striate pale eye; styles 1.5-2.5 mm. long, united to about or below the middle. In moderately acid sandy loam soils in grasslands and open oak woodlands, over much of e. Tex. except the pinelands, spring; also adj. Okla.

This taxon is divisible into three variants, the differentiating characters of which are given in the following key.

1. Leaves mostly less than 3 mm. wide; corolla tube 9 mm. long, the lobes 3 mm. wide11c. var. *humilis* Whiteh.
1. Leaves in part over 3 mm. wide (2)
- 2(1). Corolla tube 11-15 mm. long, the lobes 11 mm. long and 8 mm. wide11a. var. *grandiflora* Whiteh.
2. Corolla tube 9-12 mm. long, the lobes 7 mm. long and 5 mm. wide11b. var. *cuspidata*.

12. *Phlox carolina* L. subsp. *angusta* Wherry. Glabrescent perennial to 9 dm. tall; leaves linear to narrowly oblong-lanceolate, the lower ones to 15 cm. (rarely 17.5 cm.) long and 1 cm. wide, rapidly reduced in size and widely spaced above middle of plant; flowers short-pedicelled in a compound cyme; sepals 6-8 mm. long, united to above middle, separated by weak membranes that early become plicate, scarcely awn-tipped; corolla tube glabrous, to about 2 cm. long, the limb purple; anthers in part exerted; styles elongate, united nearly throughout, the stigmas equal to the anthers. Rare in meadows in n.e. Tex., spring; chiefly in the Coastal Plain from S.C. to Fla., Ill. and La.

FAM. 154. HYDROPHYLLACEAE R. BR.¹⁵⁶

WATERLEAF FAMILY

Herbs, less commonly shrubs, with alternate or opposite entire to variously divided or compound exstipulate leaves; flowers regular, perfect, 5-merous, gamopetalous, cymose to solitary; calyx deeply lobed; corolla tubular to rotate but usually campanulate; stamens epipetalous, as many as the corolla lobes and alternate with them, usually with a pair of scales at the base of each filament; ovary 1- or 2-celled, usually free from calyx; fruit a few- to many-seeded capsule.

About 300 species in 18 genera, chiefly in the warm-temperate regions of North America and South America.

1. Aquatic or marsh herbs; capsules truly bilocular; styles quite distinct6. *Hydrolea*, p. 1279.
1. Terrestrial herbs; capsule unilocular, often somewhat divided by intrusion of placenta; style solitary but usually shallowly lobed to bipartite (2)

¹⁵⁶ Contributed by Lincoln Constance.

- 2(1). Leaves entire; stamens unequal and/or unequally inserted; placentation axial ... 5. *Nama*, p. 1276.
2. Leaves variously toothed, lobed or divided; stamens equal and subequally inserted; placentation parietal (3)
- 3(2). Flowers numerous in scorpioid and often congested cymes; placentae narrow ... 4. *Phacelia*, p. 1274.
3. Flowers solitary or several in loose simple non-scorpioid clusters; placentae broad and lining capsule (4)
- 4(3). Herbage viscid and scented; ovules borne on both axial and abaxial faces of placentae ... 3. *Eucrypta*, p. 1274.
4. Herbage neither viscid nor scented; ovules borne only on axial face of placentae (5)
- 5(4). Auriculate appendages alternating with calyx lobes; corolla exceeding calyx; seeds provided with an elaiosome ... 1. *Nemophila*, p. 1273.
5. Calyx unappendaged; corolla shorter than or equaling calyx; seeds without elaiosomes ... 2. *Ellisia*, p. 1273.

1. NEMOPHILA NUTT.

BABY BLUE-EYES

Annual herbs with alternate, oblong to orbicular, pinnately lobed or divided leaves and large blue or purplish or small white flowers; calyx with 5 auriculate appendages, accrescent in fruit; corolla subrotate to campanulate, exceeding calyx; stamens included, a pair of scales at the base of each filament (or these rarely obsolete); style cleft about one half; capsule globose, 1- to 4-seeded; seeds subglobose or ovoid, regularly pitted, and provided with a reduced but persistent elaiosome.

Approximately 11 species; 2 in eastern, 9 in western North America.

1. Corolla showy, 10-30 mm. broad, blue or purplish; terminal flowers often cymose; capsule equaled or exceeded by the strongly accrescent calyx ... 1. *N. phacelioides*.
1. Corolla inconspicuous, to 5 mm. broad, white; flowers all solitary; capsule exceeding the weakly enlarged calyx ... 2. *N. microcalyx*.

1. *Nemophila phacelioides* Nutt. Stems rather stout, hirsute or glabrate; leaves oblong, 6-8 cm. long and 2.5-5 cm. wide, pinnately divided with 9 or 11 ovate divisions; flowers showy, solitary on axillary pedicels or in a terminal cyme; capsule 5-9 mm. in diameter. Sandy soil, usually in open woodlands in e. and s.e. Tex., Mar.-May; from Ark. and Okla. to s.e. Tex.

2. *Nemophila microcalyx* (Nutt.) Fisch. & Mey. Stems weak, sparsely hispid; leaves ovate to orbicular, 1-3.5 cm. long and 1-2.5 cm. wide, pinnately divided with 3 or 5 obovate divisions; flowers small, solitary; capsule 3-5 mm. in diameter. Damp woods, e. Tex., Mar.-May; from Fla. to Tex., n. to Va., Tenn., Ark. and Mo.

2. ELLISIA L.

AUNT LUCY

Monotypic in temperate North America.

1. *Ellisia Nyctelea* L. Delicate annual herb; stems very slender, retrorsely hispid; leaves mostly alternate, oblong to ovate, 3-8 cm. long and 1-3 cm. wide, pinnately divided into 7 to 13 oblong divisions; flowers small, white or bluish, solitary or several in a terminal cyme; calyx normally unappendaged, accrescent in fruit; corolla narrowly campanulate, shorter than to about equaling the calyx; stamens included, a pair of minute scales at the base of each filament; styles cleft less than one third; capsule globose, usually 4-seeded, 5-6 mm. in diameter, exceeded by the strongly accrescent subrotate calyx; seeds globose, regularly reticulate, without an elaiosome. Damp soil, often in woodlands, or weedy along roadsides and in cult. land, reportedly introd. in Tex.; from N.Y. and Pa. s. to Va., w. to Mich. and Okla. and as a weed as far w. as Sask., Wyo., and N.M.

3. EUCRYPTA Nutt.

Two or three species of southwestern United States and adjacent Mexico.

1. *Eucrypta micrantha* (Torr.) Heller. Viscid scented annual herb; stems weak and diffuse, often glandular; leaves mostly alternate, oblong to oval, 1-3 cm. long and 5-20 mm. wide, pinnatifidly divided into 7 or 9 oblong or spatulate lobes; flowers only 2-4 mm. broad, white or blue, clustered terminally; corolla campanulate, exceeding the calyx; scales 0 but a V-shaped fold between each filament pair; capsule globose to ovoid, 2-3 mm. in diameter; seeds 7 to 15, homomorphic and transversely corrugated. Damp shade, often about rocks, El Paso Co., Feb.-May; w. to Ariz., s.e. Calif. and adj. Mex.

4. PHACELIA Juss.

Perennial, biennial or annual herbs with prevalently alternate, simple to variously divided leaves and usually conspicuous blue to lavender or white flowers borne in scorpioid cymes; calyx unappendaged, accrescent in fruit, or not; corolla tubular to rotate, usually exceeding the calyx; stamens included or exerted, a pair of scales at the base of each filament or these sometimes obsolete and the filament bases dilated (or a gland bordered by parallel flaps between each filament pair); style shallowly bifid to nearly bipartite; capsule globose to ovoid, 2- to very many-seeded; seeds oblong to globose, terete to flattened, reticulate, pitted or transversely corrugated, sometimes excavated on each side of a salient ridge.

A polymorphic American genus of perhaps 200 species, mostly of the western United States and adjacent Mexico.

1. Delicate and mostly nonglandular annuals; corolla scales 0 but a gland bordered by parallel flaps between each filament pair; ovules 4 to 14 to each placenta; seeds not excavated (*Cosmanthus*) (2)
1. Robust, viscid, and scented annuals, biennials or perennials; corolla scales paired at base of each filament, glands 0; ovules 2 or rarely more to each placenta; seeds excavated on each side of a salient ridge (*Crenulatae*) (6)
- 2(1). Branches, pedicels and summit of ovary essentially glabrous 5. *P. glabra*.
2. Branches, pedicels and summit of ovary conspicuously pubescent (3)
- 3(2). Basal leaves forming a conspicuous rosette, shallowly toothed or lobed; fruiting pedicels usually strictly erect, short in comparison with calyx 1. *P. strictiflora*.
3. Basal leaves scarcely rosulate, pinnate or pinnatifid; fruiting pedicels spreading-ascending to reflexed, slender (4)
- 4(3). Stem leaves all or nearly all petiolate; pubescence sparse 3. *P. laxa*.
4. At least upper stem leaves sessile; pubescence dense (5)
- 5(4). Stem leaves dentate or shallowly lobed; ovules 6 to 12 to each placenta; seeds usually 10 to 15 2. *P. patuliflora*.
5. Stem leaves deeply lobed to pinnatifid; ovules usually 4 to each placenta; seeds 6 to 8 4. *P. hirsuta*.
- 6(1). Ovules 10 to 12 to each placenta; seeds more than 4 6. *P. infundibuliformis*.
6. Ovules regularly 2 to each placenta; seeds no more than 4 (7)
- 7(6). Stamens included or equaling corolla; corolla 3-4 mm. long and broad; calyx conspicuously glandular 7. *P. coerulea*.
7. Stamens conspicuously exerted (8)
- 8(7). Corolla narrow, funnellform or salverform, 5-7 mm. long and broad; seeds not corrugated (9)
8. Corolla broader, campanulate; seeds corrugated or not (10)

- 9(8). Basal leaves oblong to narrowly ovate, 7-25 mm. wide; corolla funnelform, 5-6 mm. long; seeds oval 8. *P. integrifolia*.
9. Basal leaves broadly ovate to orbicular, 30-70 mm. wide; corolla salverform, 6-7 mm. long; seeds oblong 9. *P. robusta*.
- 10(8). Leaves 1- to 2-pinnate or pinnatifid; seeds without transverse corrugations (11)
10. Leaves sinuate-dentate or crenately lobed; seeds transversely corrugated (12)
- 11(10). Corolla lobes crenulate or dentate; calyx lobes oval, hispid
..... 10. *P. Popei*.
11. Corolla lobes essentially entire; calyx lobes narrow, softly hirsute
..... 11. *P. congesta*.
- 12(10). Inflorescence cymose or paniculate; corolla 5-6 mm. long and broad
..... 12. *P. intermedia*.
12. Inflorescence thyrsoid; corolla 7-8 mm. long, 6-7 mm. broad
..... 13. *P. texana*.

1. *Phacelia strictiflora* (Engelm. & Gray) Gray. Hirsute or hirsutulous annual, branching or simple from a basal rosette; leaves oblong to oval, 1-6 cm. long, 5-30 mm. wide, with 1 to 6 pairs of teeth or lobes, the cauline leaves sessile; flowers purplish-lavender, rotate-campanulate, 8-20 mm. broad; capsule globose-ovoid, 3-6 mm. in diameter; seeds 10 to 20. Sandy soil of woods and fields, cen. and e. Tex., Mar.-May; e. to Ala., n. to Okla.

Several varieties are distinguishable on the basis of pubescence, leaf lobing and shape of calyx. The following key distinguishes these, all of which occur sympatrically in Texas.

1. Basal leaves bright-green, glabrate beneath, persistently rosulate; calyx of lower flowers disproportionately enlarging in fruit var. *Lundelliana* Const.
1. Basal leaves grayish, pubescent beneath, the rosettes withering early; calyx of all flowers enlarging subequally (2)
- 2(1). Pubescence loosely spreading; calyx lobes broad .. var. *strictiflora*.
2. Pubescence appressed; calyx lobes narrow (3)
- 3(2). Stem leaves crowded, deeply saliently lobed, the lobes acute
..... var. *connexa* Const.
3. Stem leaves rather remote, subpinnatifid, with obtuse lobes
..... var. *Robbinsii* Const.

2. *Phacelia patuliflora* (Engelm. & Gray) Gray. Densely hirsute to finely strigulose, branching, frequently decumbent annual, without an evident basal rosette; leaves oblong to broadly oval, 2-10 cm. long, 1-4 cm. wide, pinnately lobed to pinnatifid with 1 to 7 pairs of lobes, the cauline leaves mostly sessile; flowers lavender to purplish-violet, often white-centered, broadly campanulate 8-20 mm. broad; capsule globose, 4-6 mm. in diameter; seeds 10 to 15. Var. *teucrifolia* (I. M. Johnst.) Const. (*P. teucrifolia* I. M. Johnst.) is distinguished by its rather stiffly ascending branches and fruiting pedicels and acute calyx lobes. Sandy soil of woodlands and alluvial terraces, cen. and s.e. Tex., Mar.-May; s. to adj. Mex.

3. *Phacelia laxa* Small. Diffuse, sparsely hirsute annual; leaves oblong-oval to oval, 2-8 cm. long, 12-35 mm. wide, pinnate or pinnatifid with 1 or 2 pairs of small basal leaflets and a much larger terminal leaflet or lobe, the cauline leaves mostly prominently petiolate; flowers pale-bluish-lavender with a whitish center, broadly campanulate, 8-12 mm. broad; capsule globose, 3-5 mm. in diameter; seeds 4 to 8. *P. prostrata* Brand. Moist heavy soil of shaded alluvial thickets, s.e. Tex., Mar.-May; endemic.

4. *Phacelia hirsuta* Nutt. Densely pubescent, erect or ascending annual; leaves oblong, 2-4.5 cm. long, 8-25 mm. wide, pinnate or pinnatifid with 2 to 4 pairs of lobes; flowers bluish-lavender with a whitish center, rotate-campanulate, 8-13 mm. broad; capsule subglobose, 3.5-4 mm. in diameter; seeds 6 to 8. Sandy soil of borders and openings in deciduous woods, n.e. Tex., Mar.-May; La. to Tex., n. to s. Mo. and s.e. Kan.

5. *Phacelia glabra* Nutt. Glabrescent, slightly succulent, erect or ascending annual; leaves oblong to oblong-oval, 1.5-4 cm. long, 5-15 mm. broad, pinnate or pinnatifid with

2 to 4 pairs of lobes; flowers bluish-lavender with a whitish center, rotate-campanulate, 5-12 mm. broad; capsule globose, 3-4 mm. in diameter; seeds 4 to 8. Sandy loam of prairies and borders of deciduous woods in n.e. Tex., Mar.-May; n. to Ark. and e. Okla.

6. *Phacelia infundibuliformis* Torr. Rather stout viscid-canescens branched annual; basal leaves oblong, 3.5-10 cm. long, 25-65 mm. wide, pinnate and the leaflets often petiolulate or pinnatifid, the cauline often petiolate; flowers purplish, funnellform, 6-7 mm. long and 5-6 mm. broad; capsule oblong, 5 mm. long; seeds usually 8 to 15, not corrugated. Rock crevices along the upper Rio Grande of w. Tex.; Tex., N.M. (?), Coah. and Chih.

7. *Phacelia coerulea* Greene. Slender viscid many-stemmed annual; leaves broadly ovate to oblong-ovate, 3-8 cm. long, 1-2.5 cm. wide, shallowly cleft to pinnatifid, the cauline often long-petiolate; flowers blue or white, campanulate; capsule ovoid, 2-3 mm. long; seeds 4, corrugated. *P. invenusta* Gray. Rocky slopes in extreme w. Tex., Mar.-May; w. to Ariz. and s.e. Calif., s. to Chih.

8. *Phacelia integrifolia* Torr. Stout viscid mostly unbranched annual or biennial; basal leaves oblong to narrowly ovate, 2-7 cm. long, 7-25 mm. wide, crenate to shallowly pinnatifid, the cauline usually sessile; flowers purplish-lavender, funnellform; capsule ovoid-globose, 3.5 mm. long; seeds 4, not corrugated. *P. arenicola* Brandeg. Rocky or sandy soil, particularly gypsum or limestone, in w. and n. Tex., Mar.-May; n. to Okla. and Kan., w. to Ut. and Ariz., s. to Chih.

9. *Phacelia robusta* (Macbr.) I. M. Johnst. Stout viscid mostly unbranched annual or biennial; basal leaves broadly ovate to orbicular, 3-15 cm. long, 3-7 cm. wide, irregularly crenate to shallowly lobed, the cauline often petiolate; flowers pink or pale-lavender, salverform; capsule ovoid-globose, 3-4 mm. long; seeds 4, not corrugated. *P. integrifolia* var. *robusta* Macbr. The relationship of this to the preceding taxon deserves further study. Rocky places in the mts. of w. Tex. to n. Tex. (?), May-Aug.; s. to Coah. and Chih.

10. *Phacelia Popei* T. & G. Low diffuse viscid-pubescent annual, branching from base; leaves narrowly oblong, 2-15 cm. long, 1-3 cm. wide, 1- to 2-pinnate with linear or lanceolate divisions; flowers blue to purplish [var *similis* (Woot. & Standl.) J. Voss] or white (var. *Popei*), campanulate, 3.5-7 mm. long and broad; capsule globose, 2 mm. in diameter; seeds 4, not corrugated. Sandy or rocky soil, often limestone or gypsum, w. Tex., Apr.-May; Tex., N.M. and Chih.

11. *Phacelia congesta* Hook. Diffuse or erect, variously pubescent and usually somewhat viscid annual or biennial; leaves ovate, 3-10 cm. long, 3-4 cm. wide, 1- to 2-pinnate or pinnatifid; flowers blue or purplish, or white (var. *rupestris* Macbr.), campanulate, 5-7 mm. long and 3-6 mm. broad; capsule ovoid, 2-3 mm. long; seeds 4 or 2 (var. *dissecta* Gray), not corrugated. Sandy, gravelly or rocky soil, distributed almost throughout the state except e. Tex., Mar.-June; Tex., N.M., Ariz., Chih., Coah. and N.L.

12. *Phacelia intermedia* Woot. Viscid erect annual, branching from base or simple; leaves lanceolate to oblong, 3-14 cm. long, 5-20 mm. wide, crenately lobed, the lobes again crenate; flowers purplish, campanulate, 6 mm. long and broad; capsule globose, 3-3.5 mm. in diameter; seeds 4, corrugated. Perhaps only a phase of the widespread and variable *P. crenulata* Torr. Sand, gravel and rocky slopes, sometimes on limestone, w. Tex., Feb.-Apr.; w. to N.M., Ut. and Ariz.

13. *Phacelia texana* J. Voss. Stout erect glandular-viscid biennial, with small ascending branches; leaves narrowly lanceolate to oblong, 8-12 cm. long, about 2 cm. wide, coarsely sinuate-dentate; flowers purplish to pink, campanulate, 7-8 mm. long, 6-7 mm. broad; capsule globose, 2.5-3 mm. in diameter; seeds 4, oblong, transversely corrugated. Except for the corrugated seeds, this closely resembles *P. integrifolia* and *P. robusta*. On clay shale in the Trans-Pecos, Mar.-May; endemic.

5. NAMA L.

Low, pubescent annual or occasionally perennial herbs with mostly alternate, essentially entire leaves and conspicuous or inconspicuous white to purplish-violet flowers in non-scorpioid terminal cymes or solitary; calyx usually divided nearly to base, unappendaged, little-acrescent; corolla tubular to broadly funnellform or campanulate, usually exceeding calyx; stamens included, usually unequal and unequally inserted, filament base usually

mm. wide; flowers lavender, solitary or in small terminal clusters; calyx lobes linear, 4-5 mm. long; corolla tubular-funnelform, 6-8 mm. long; stamen bases dilated into free-margined, toothed scales much shorter than the free filament; seeds yellow, reticulate. Rock crevices in the mts. of extreme w. Tex., July-Sept.; endemic.

3. *Nama serpylloides* Hemsl. Prostrate, diffusely branched, subsericeous perennial, the slender, leafy branches 1-4 dm. long; leaves mostly opposite, obovate or obovate-spatulate, somewhat revolute, 7-15 mm. long and 2-4 mm. wide; flowers pink, solitary or paired; calyx lobes linear, 2-3 mm. long; corolla funnelform-campanulate, 5-10 mm. long; stamen bases slightly dilated into narrowly free-margined scales much shorter than the free filament and extending to base of corolla; seeds brown, shallowly pitted. Gravelly soil of brushland, s. Tex., Mar.-Apr.; also Coah.

4. *Nama parvifolium* (Torr.) Greenm. Prostrate, diffusely branched, subsericeous annual or perennial, the slender leafy branches 2-20 cm. long; leaves alternate or opposite at least toward tips of branches, oblanceolate to obovate, somewhat revolute, 5-24 mm. long, 3-10 mm. wide; flowers pink or purplish, 1 or 2 in leaf axils; calyx lobes linear-lanceolate, 5-7 mm. long; corolla funnelform-campanulate, 7-12 mm. long; stamen bases slightly dilated into narrowly free-margined scales much shorter than the free filament and extending to base of corolla; seeds brown, shallowly pitted. Rocky limestone slopes of Rio Grande Plains and Edwards Plateau, Apr.-July; also Tam. and N.L.

5. *Nama jamaicense* L. Prostrate or ascending, strigose-hirsute, leafy annual, branching from base, the branches 1-5 dm. long; leaves alternate, spatulate to obovate, 15-80 mm. long, 5-35 mm. wide, plane, conspicuously decurrent at base to form a winged stem; flowers white, usually solitary in upper leaf axils; calyx lobes linear or linear-spatulate, enlarging and adherent to ovary in fruit; corolla nearly tubular, 6-7 mm. long; stamen bases dilated into free-margined scales shorter than the free filament; seeds brown, finely alveolate. Moist places under shrubs and elsewhere in e. and s.e. Tex., Apr.-July; e. to Fla. and s. to W.I. and C.A.

6. *Nama stenocarpum* Gray. Prostrate to ascending or erect sparsely hirsute annual, branching from base, the leafy branches 1-3 dm. long; leaves alternate, oblong to spatulate, 1-4 cm. long, 2-10 mm. wide, often undulate, sometimes clasping; flowers lavender, solitary or paired at nodes; calyx lobes linear-spatulate, 4-7 mm. long, calyx tube adnate to the inferior ovary; corolla tubular-campanulate, 5-7 mm. long, little longer than calyx; stamen bases dilated into free-margined scales about equaling the free filament; seeds yellowish, finely alveolate. Mud of poorly drained clay soil in s. and s.e. Tex., Mar.-May; w. to Ariz. and Calif., s. to adj. Mex.

7. *Nama undulatum* H.B.K. Prostrate or ascending, villous-hirsute, glandular annual, branching from base, the branches 1-3 dm. long; leaves alternate, oblong-lanceolate to spatulate, 15-20 mm. long, 2-12 mm. wide, undulate, often clasping; flowers pink, clustered in few-flowered terminal and lateral cymes; calyx lobes linear-spatulate, enlarging but free in fruit; corolla funnelform-campanulate, 6-9 mm. long; stamen bases dilated into free-margined scales about equaling the free filament and extending to base of corolla; seeds yellow, finely alveolate. Gravelly soil in brushland and elsewhere from the Rio Grande Plains and Edwards Plateau to the Trans-Pecos, June-Aug.; s. to cen. Mex. and in Chile and Arg.

8. *Nama torynophyllum* Greenm. Prostrate, matted, leafy, densely villous annual, with very short branches; leaves alternate, spatulate, revolute and spoon-shaped, 1 cm. long, 1.5-4 mm. wide; flowers white or pinkish, numerous, arranged singly along the branches; calyx lobes linear-spatulate, 3-3.5 mm. long; corolla tubular, 3-4 mm. long; stamen bases not dilated, the adnate portion much shorter than the free filament; seeds brown, shallowly pitted. Gravel bars along the Rio Grande and tributaries in Brewster Co., Feb.-Apr.; also Coah.

9. *Nama Havardii* Gray. Erect, villous, leafy, persistent annual, stoutly branching from near base, 1.5-4 dm. tall; leaves alternate, oblong to oval-spatulate, strongly revolute to plane, petiolate, 2-4 cm. long, 4-13 mm. wide; flowers pale-pink or white, numerous in small terminal and lateral clusters; calyx lobes linear-spatulate, 6-9 mm. long; corolla funnelform-campanulate, 8-12 mm. long; stamen bases dilated into broadly free-margined scales much longer than the free filament; seeds brown, shallowly pitted. Gravelly bars, washes and slopes in the Big Bend area of w. Tex., Apr.-June; endemic.

10. *Nama Stevensii* C. L. Hitchc. Grayish-strigose, erect or ascending annual, usually branched from base and forming dense rounded clumps; leaves alternate, linear-lanceolate, strongly revolute, sessile, 1-3 cm. long, 1-3 mm. wide; flowers lavender, in small axillary clusters usually exceeded by the leaves; calyx lobes linear-lanceolate, 5-8 mm. long, corolla funnelform-campanulate, 8-10 mm. long; stamen bases dilated into narrowly free-margined scales about equaling the free filament; seeds yellow, alveolate. Perhaps only a gypsophilous phase of *N. hispidum*. On sandy gypsum soils of the Rolling Plains and Trans-Pecos, May-July; also Okla.

11. *Nama hispidum* Gray. Strigose-hispid and hirsute erect or ascending annual, freely branched from base or only above, 1-5 dm. tall; leaves prevalently alternate, linear-oblong to obovate, plane to strongly revolute, mostly narrowed at base, 1-7 cm. long and 1-8 mm. wide; flowers pink to bright-purple, solitary or in small terminal clusters; calyx lobes linear-lanceolate, 4-7 mm. long; corolla funnelform-campanulate, 8-15 mm. long; stamen bases scarcely dilated, the adnate portion shorter than the free filament; seeds yellow, finely alveolate. A widespread and extremely variable species; the described varieties, based on habit and foliar characters, are confused. In sand and on gravelly soil in diverse habitats almost throughout Tex., Mar.-July; n. to Okla., w. to Ariz. and Calif.

12. *Nama dichotomum* (R. & P.) Choisy. Erect or ascending, sparsely leafy, usually dichotomously branching annual 5-20 cm. tall; leaves alternate, linear to narrowly oblanceolate or spatulate, plane, petiolate, 1-3 cm. long, 2-5 mm. wide; flowers pale-lavender, borne singly or in pairs in the upper branches; calyx lobes linear to narrowly spatulate, 5-10 mm. long; corolla tubular-campanulate, about 5 mm. long; stamen bases dilated into free-margined scales shorter than the free filament; seeds brown, prominently large-pitted. Gravelly summit of Mt. Livermore, Jeff Davis Co., 8,000 ft. elev., Aug.-Sept.; w. to Colo., N.M. and Ariz.; highlands of Mex. and in temp. S.A.

6. HYDROLEA L.

Annual or perennial, usually spiny, aquatic or marsh herbs with alternate entire leaves and corymbose or cymose blue flowers; calyx unappendaged, not conspicuously accrescent; corolla rotate-campanulate, exceeding or equaling the calyx; stamens included or exserted; corolla scales 0; styles distinct; capsule ovoid or globose, many seeded, often dehiscing irregularly; seeds minute, striate or rugose.

Approximately 20 species, pantropical, but predominantly subtropical America.

1. Plants essentially glabrous; leaves lanceolate; flowers in small axillary clusters, the calyx essentially glabrous 3. *H. uniflora*.
1. Plants conspicuously pubescent; leaves oblong to ovate; flowers in terminal clusters, the calyx hirsute (2)
- 2(1). Foliage and inflorescence finely hirtellous; anthers slightly exserted 1. *H. ovata*.
2. Foliage and inflorescence hirsute and usually glandular; anthers included 2. *H. spinosa*.

1. *Hydrolea ovata* Choisy. Stout erect spiny hirtellous perennial; leaves 3-6 cm. long, 15-25 mm. wide; flowers showy, 15-25 mm. broad; sepals shorter than corolla. Edges of ponds and streams in e. and s.e. Tex., Sept.-Oct.; La. to Tex., n. to Miss. and Ark.

2. *Hydrolea spinosa* L. Stout erect usually very spiny perennial, hirsute and usually glandular; leaves 3-12 cm. long, 5-30 mm. wide; flowers showy, 1-1.5 cm. broad; sepals shorter than corolla. Cameron Co., June; s. to Mex., W.I., and C.A. and S.A.

3. *Hydrolea uniflora* Raf. Slender weakly erect spiny glabrous perennial; leaves 5-8 cm. long, 1.5-2 cm. wide; flowers rather inconspicuous, 1-1.5 cm. broad; sepals equaling corolla. *H. affinis* Gray. Edges and shallow water of ponds and streams in e. and s.e. Tex., Sept.-Oct.; n. to Ark., Mo. and s. Ill.

A colony of plants found in Red River County represents what is undoubtedly the product of crossing between *H. uniflora* and *H. ovata*. The plants are strikingly intermediate between these two species in pubescence and corolla.

FAM. 155. BORAGINACEAE JUSS.¹⁵⁷

BORAGE FAMILY

Plants herbaceous, shrubby or arborescent, usually bristly; leaves simple, alternate; flowers perfect, regular, solitary or cymose; cymes glomerate-racemose or spicate, frequently unilateral and coiled (scorpioid), usually with bracts between, to one side of, or opposite the flowers; calyx usually deeply lobed, somewhat irregular; corolla 5-lobed, commonly with folds or saccate-intruded appendages in the throat; stamens 5, borne on the corolla tube alternate with the lobes; ovary superior, bicarpellate, usually 4-ovulate, entire or lobed, becoming tough or bony at maturity; fruit commonly breaking up into 4 single-seeded lobes (achenelike mericarps) or remaining intact but the mesocarp becoming fleshy and the fruit thus drupaceous; style lobed or entire, seated in the pericarp at the apex of the fruit or borne between the fruit lobes (nutlets) on the receptacle, or on an upward prolongation thereof (gynobase); endosperm absent or scarce.

The classification of this large family is based primarily upon the structure of the fruit. In many cases it is very difficult to recognize the genus and almost impossible to obtain a precise identification of the species if the specimens lack mature fruiting structures. *Cordia* and *Ehretia* are now commonly placed in the segregate family Ehretiaceae. Numerous species are cultivated as ornamentals, notably in the genera *Heliotropium* (heliotrope), *Anchusa*, *Echium*, and *Myosotis* (forget-me-not).

1. Ovary entire or shallowly lobed, the style terminal (2)
 1. Ovary deeply 4-lobed, the style borne on the gynobase and arising between the lobes of the ovary (6)
 - 2(1). Style cleft twice, the four branches each bearing a stigma1. *Cordia*, p. 1281.
 2. Style cleft or divided once or simple or none (3)
 - 3(2). Style distinctly cleft or divided (4)
 3. Style simple, very short or absent; stigma annular-peltate, surmounted by a conical or cylindrical, simple or lobed appendage (5)
 - 4(3). Style shallowly cleft or two-lobed2. *Ehretia*, p. 1282.
 4. Style deeply cleft or divided to the base3. *Coldenia*, p. 1282.
 - 5(3). Fruit with a fleshy mesocarp; large shrubs4. *Tournefortia*, p. 1285.
 5. Fruit dry, without a fleshy mesocarp; herbaceous or small subshrubs5. *Heliotropium*, p. 1285.
- 6(1). Mericarps spreading apart at maturity, attached to the gynobase by their apical ends; attachment scar (areola) not extending below middle of the ventral surface of the mericarp (7)
 6. Mericarps more or less erect and parallel at maturity, attached basally, basilaterally or medially to the gynobase (8)
 - 7(6). Dorsal surface of mericarp without glochidiate prickles; mericarps with a cupulate margin6. *Omphalodes*, p. 1291.
 7. Dorsal surface of mericarp armed with glochidiate prickles; mericarps with a raised margin or the margin indistinct or absent7. *Cynoglossum*, p. 1291.
 - 8(6). Mericarps attached medially or basilaterally, if nearly basal, the attachment scar always small or with a substipitate prolongation (9)
 8. Mericarps attached basally to the broad, low gynobase; attachment scar large and broad, sometimes surrounded by a low rim (14)
 - 9(8). Mericarps conspicuously armed with glochidiate prickles (10)
 9. Mericarps smooth or roughened, lacking glochidiate prickles (11)
 - 10(9). Pedicels erect or ascending in fruit; racemes bracteate; mericarps attached to the subulate gynobase all along their ventral keel, free near the base; plants mostly annuals8. *Lappula*, p. 1292.

¹⁵⁷ Adapted from I. M. Johnston in C. L. Lundell, *Flora of Texas* I:123-221. 1964. See Appendix.

10. Pedicels recurved or deflexed in fruit; racemes naked or sparsely bracted; mericarps attached medially to the broadly pyramidal gynobase by a broad areola; plants mostly perennials or biennials 9. *Hackelia*, p. 1293.
- 11(9). Corolla lobes convolute in bud; in ours the calyx tube with spreading uncinat hairs; mericarps smooth, attached near the base, the scar very small 12. *Myosotis*, p. 1302.
11. Corolla lobes imbricate in bud; calyx tube with straight hairs; mericarps mostly roughened (excepting a few species in *Cryptantha*), variously attached (12)
- 12(11). Mericarps without a ventral keel, but with a closed or narrowly open ventral groove extending most of the length of the mericarp, the groove forked at the base or ending in a depressed areola 10. *Cryptantha*, p. 1294.
12. Mericarps with a ventral keel, not grooved (13)
- 13(12). Annuals; corolla bright-orange or yellow, throat open or constricted; mericarp with an elevated carunclelike inframedial attachment scar lying below the ventral keel 11. *Amsinckia*, p. 1301.
13. Perennials; corolla blue to whitish, throat closed by appendages; mericarp with a broad inframedial areola or with a substipitate basal prolongation of the ventral keel 13. *Antiphytum*, p. 1303.
- 14(8). Corolla irregular, the upper lobes usually longer than the lower ones; stamens not all equal in length 17. *Echium*, p. 1311.
14. Corolla regular; stamens all equal in length (15)
- 15(14). Corolla lobes acute or acuminate, erect; style long-exserted 16. *Onosmodium*, p. 1309.
15. Corolla lobes rounded or obtuse, ascending or spreading or recurved; style included or short-exserted (16)
- 16(15). Inside of corolla throat without guide lines; stipitate glands or faucal appendages or both present, scattered or localized in groups 14. *Lithospermum*, p. 1304.
16. Inside of corolla throat with 5 well-developed elongate, vertical guide lines consisting of crowded hairs and stipitate glands 15. *Buglossoides*, p. 1309.

1. CORDIA L.

Trees or shrubs; leaves small to large, usually evidently petiolate, margin entire, crenate, serrate or rarely even lobulate; cymes ebracteate, mostly corymbose; flowers homomorphic or heterostyled or functionally more or less unisexual (functionally male flowers with style and stigmas much reduced or completely undeveloped); corolla campanulate to funnelform, small to large, white, yellow, orange, or red, usually 5-merous but occasionally 4- to 8-merous, lobes ascending to recurved, tube short to long, cylindrical or expanding; stamens exserted or included, filaments often hairy towards the base, usually well-developed; style terminal on ovary, dichotomous, a simple column at base, then dividing into two branches which in turn fork to produce the four ultimate branches each bearing a stigma; stigmas 4, clavate to spatulate or capitate; fruit a drupe with watery or glutinous mesocarp or rarely without fleshy mesocarp and hence a nut; endocarp bony, 1- to 4-seeded; seeds without endosperm; cotyledons plicate.

About 250 species of tropical or warm temperate trees and shrubs having the majority of its species and its center of greatest diversity in America.

1. Large shrub or tree over 1 m. tall; leaf margin entire or minutely toothed; corolla 35 mm. or more long 1. *C. Boissieri*.
1. Small shrub less than 1 m. tall; leaf margin coarsely serrate or sinuately toothed or lobed; corolla less than 20 mm. long 2. *C. podocephala*.

1. *Cordia Boissieri* A. DC. ANACAHUTTE. Shrub or small tree to 8 m. tall and with a trunk to 2 dm. in diameter, the thick bark gray and ridged; leaves with a petiole to 4 cm. long, thick, firm, ovate to lance-ovate, to 2 dm. long and 15 cm. wide, rounded to shallowly cordate at base, broadly obtuse to acute apex, scabrous on upper surface, softly

tomentose on lower surface; flowers heterostylic, crowded into 6- to 8-flowered cymes that are grouped into a corymbose inflorescence; calyx tube cupulate or cylindric, 8-16 mm. long, the teeth acute; corolla funnellform, white with a yellow throat, 35-45 mm. long, the lobes rounded and crispate-erose; fruit ovoid, 2-3 cm. long, reddish-brown, shiny, the flesh sweet. In thickets, chaparral, fencerows, on gravelly slopes and along stream banks of the Rio Grande Plains and brushlands of extreme s. Tex. (n. to Jim Hogg, Hidalgo and Willacy cos.), throughout the year; Tex. s. to Coah., Tam., N.L. and S.L.P.

Often planted as an ornamental as far north as Corpus Christi and San Antonio but tending to freeze back in cold winters.

2. *Cordia podocephala* Torr. Small fruticose perennial, from a woody reddish-brown root; stems few, erect, simple or with few strictly ascending branches, 3-6 dm. tall, 1-2 mm. thick, antrorsely strigose; leaves to 9 cm. long and 25 mm. wide, narrowly lanceolate to oblanceolate or sometimes somewhat ovate, acute to obtuse at apex, the base acute and contracted into a short petiole, pinnately veined, strigose on both surfaces and paler on the lower surface, the margin coarsely serrate or sinuately toothed or lobed; inflorescence a globose dense head before anthesis, 5-10 mm. thick, on a naked peduncle to 18 cm. long, terminal on the shoot or extra-axillary along the leafy stem; calyx strigose, just before opening 3-4 mm. long, ovoid, the apex obtusely pointed, lobes triangular, valvate, with the tip sharply acute but not appendaged; corolla white, delicate, 12-18 mm. long, funnellform, coarsely emarginate; drupe included and tightly invested by the saclike calyx. On rocky hills and outcrops, in wooded arroyos, on mesquite plains, and similar situations in s. Tex. (n. to Bexar and Medina cos.), May-Oct.; Tex., Tam., N.L. and Coah.

2. EHRETIA L.

This genus consists of about 50 species in Africa, southern Asia, the East Indies and several in America.

1. *Ehretia Anacua* (Teran & Berl.) I. M. Johnst. SUGARBERRY, KNOCK-AWAY, ANACUA. Tree to 15 m. tall, usually with multiple trunks and thick furrowed bark separating into thin gray or reddish scales, the foliage somber-green, evergreen or seasonally partially deciduous in northern parts of its geographic range; leaves distinctly petiolate, elliptic to ovate or less commonly broadly lanceolate, 3-12 (usually 3-6) cm. long and 1.5-8 (usually 2-3) cm. wide, the margin entire or rarely coarsely toothed above the middle, frequently somewhat revolute, rounded to obtuse at base, at apex usually obtuse and frequently with the very tip apiculate, upper surface bearing abundant mineralized disks from which arise short stout sharply pointed minute antrorsely appressed hairs that make the surface decidedly scabrous, lower surface paler than the above surface and thinly velvety or glabrous except for short slender scattered hairs along the midrib and veins and for the hair clusters in the axils of the principal veins; inflorescence terminal on the younger leafy twigs, 1.5-7 cm. long; flowers fragrant; calyx lobed almost to the base, the lobes lanceolate, slightly unequal with the abaxial one largest, at anthesis lobes 2.5-3.5 mm. long and 0.5-1 mm. broad, almost doubling in size at maturity; corolla white, 6-7 mm. long, becoming 2.5-4 mm. broad at summit, the lobes ovate or elliptic; drupe orange-color or dark-yellow, globose, 5-8 mm. thick, containing 2 hemispheric stones (each 2-seeded) surrounded by a thin juicy edible flesh. *E. elliptica* A. DC. In thickets, forests, palm groves and open forests, along fencerows and brushlands in s. Tex. (n. to Hays and Travis cos.), June-Oct.; also Tam. and N.L.

Often planted as an ornamental as far north as Dallas where it may die back in excessively cold winters.

3. COLDENIA L.

Herbaceous or suffruticose plants with slender, forking, usually prostrate or widely spreading stems; leaves small and numerous, subsessile or petiolate; flowers generally extra-axillary, along leafy twigs or at the forks of the branches, sometimes glomerate, commonly opening late in the afternoon; corolla mostly small, with cylindric or ampliate tube and spreading lobes, throat naked or sometimes appendaged; style terminal on ovary,

short to long, bilobed or biparted; stigmas 2, not conspicuously differentiated from the style branch; fruit dry, pyramidal or hemispheric or more or less obviously 4-lobed, dividing into usually 4 single-seeded achenelike mericarps; mericarps more or less broadly united ventrally or joined to a central prolongation of the receptacle.

Except for a single Old World species, the remaining 19 are entirely confined to arid regions of America.

1. Plant a small erect bush; flowers and fruit aggregated into dense globose clusters terminating the leafy branches and branchlets; bracts inconspicuous, simulating the filiform, plumose, very elongate calyx lobes; fruit normally maturing only a single ovule 1. *C. Greggii*.
1. Plant low and spreading, usually prostrate; flowers and fruit borne in the leaf axils or mixed among leaves in leaf clusters borne along the leaf-bearing branches and branchlets (2)
 - 2(1). Fruit nearly globose, unlobed, at maturity breaking apart into quarter sections, each quarter forming a mericarp; leaf blades commonly elliptic or ovate; plant pallid, tomentose 2. *C. canescens*.
 2. Fruit deeply 4-lobed, the lobes joined only by their inner angle, each lobe forming a mericarp (3)
 - 3(2). Leaves with a slender elongate petiole, half to nearly as long as the usually elliptic or ovate blade, not conspicuously broadened, thickened and indurate below the middle; plant pallid, tomentose (4)
 3. Leaves with a narrow elongate blade borne on a short broadened ovate or triangular petiole which is always thickened and indurate in age (5)
 - 4(3). Corolla in the bud minutely glandular, but otherwise glabrous 3. *C. mexicana* var. *mexicana*.
 4. Corolla in the bud distinctly villulose, not at all glandular or only very sparsely and inconspicuously so; corolla perhaps averaging smaller than in the typical form and the older stems possibly becoming somewhat more fruticulose 3a. *C. mexicana* var. *tomentosa*.
- 5(3). Corolla bud bearing abundant minute stipitate glands, otherwise glabrous; attachment scar on mericarp entirely closed or opened only above the middle; leaves usually cinereous, blade as broad or slightly broader than the broad petiole, lower surface not entirely covered by the inrolled margins 4. *C. gossypina*.
5. Corolla bud villulose, or rarely also sparsely glanduliferous; attachment scar on mericarps open for its entire length or at least below the middle; leaves usually green, the blade usually very slender and narrower than the broad base of the petiole, only the midrib on the lower surface not covered by the strongly inrolled leaf margins 5. *C. hispidissima*.

1. *Coldenia Greggii* (T. & G.) Gray. Shrub more or less globose, 1-3 dm. but at times 5 dm. or more tall, becoming much-branched, very twiggy and compact in age; leaves numerous, shortly petiolate, ovate to elliptic, 5-9 mm. long, 2.5-6 mm. wide, usually densely tomentulose and pale on the lower surface, usually pale or slightly tawny and densely tomentulose with an admixture of stout coarse usually appressed hairs on upper surface; flower clusters 1-2 cm. in diameter; calyx sessile, eventually with the mature fruit tightly embraced by the base of the lobes detaching and the whole calyx functioning as a means of wind dissemination, the lobes very slender and elongate, subulate-filiform, decidedly unequal, 5-9 mm. long, plumose with an abundance of very slender long spreading hairs and bearing also minute inconspicuous gland-tipped hairs, usually somewhat smoke-colored or more or less purplish at maturity; corolla pink to magenta, 6.5-8 mm. in total length; fruit at maturity lance-ellipsoidal, 2-2.5 mm. long, 1-1.2 mm. thick near the middle, by abortion always one-celled and one-seeded, thin-walled (not at all bony!), indehiscent, dorsal side usually lustrous and above the middle sparsely hispidu-

lous, ventral side bearing dull pale papery tissue representing the three aborted cells of the fruit. Usually found only on and about exposures of limestone in the Trans-Pecos, Mar.-Aug.; also N.M., e. Chih., w. and s. Coah., to n. Zac. and Dgo.

2. *Coldenia canescens* DC. OREJA DE FERRO. Plant from a woody taproot, suffrutescent, to 1 dm. tall and 3 dm. thick, the usually numerous leaf stems and branches pallid, tomentose; leaves numerous, shortly petiolate, ovate to elliptic or elliptic-lanceolate, obtuse or broadly acute at the ends, 7-15 mm. long, 2.5-9 mm. broad, thickish, the margins narrowly somewhat revolute, densely pale tomentose on lower surface, with a thinner tomentum intermingled with short stiffish usually appressed hairs that arise from discoid or thickened bases on upper surface; calyx sessile, persistent, at anthesis 3-4 mm. long, the lobes about as long as the corolla tube, unequal, united above the base; lobes of the fruiting calyx lanceolate, usually long-attenuate, 4-7 mm. long, below the middle 1-1.5 mm. broad and scarious margined, and tightly embracing the ovoid-globose fruit almost to its apex; corolla 5-6 (-8) mm. in total length, pink, rose or rarely white, the broadly rounded lobes 1.8-3 (-4.5) mm. broad and 1.5-2 (-3.5) mm. long, the margins frequently erose; fruit at maturity glabrous or hairy, 2.5-3 mm. in diameter, 2-2.5 mm. high, the pericarp marked by 4 equispaced longitudinal grooves. In the Trans-Pecos, e. to Mitchell and Tom Green cos. and s.e. to Hidalgo Co., Mar.-Aug.; also s. N.M. and Mex. (extending s. to the states of Hgo. and Qro.).

A very pronounced calciphile, growing on limestone, caliche or rocky calcareous soils.

It is quite possible that the more western plant (Calif. to N.M., s. to n. Mex.), segregated as var. *subnuda* I. M. Johnst., may be found in Brewster and Presidio cos. It is a coarser and less depressed plant with usually larger, more rounded, greener leaves, and a more sparsely tomentose indument that contains coarser, more spreading hairs.

3. *Coldenia mexicana* Wats. var. *mexicana*. Plant forming mats from a woody taproot, tomentose, usually pale, 2-5 dm. broad, the older stems fruticulose but never very strong and rigid; leaves white tomentose, clustered, borne mostly on short branchlets along the main stem and branches, thickish, veinless, elliptic to somewhat ovate or broadly lanceolate, to 1 cm. long and 6 mm. broad, acute to broadly obtuse at both ends, the margins revolute, both surfaces white tomentose, the upper surface also sparsely hispid (discoid bases of bristles hidden in the tomentum); calyx sessile, firmly affixed, at anthesis 4-4.5 mm. long, the lobes slender, gradually attenuate, villose and sparingly hispidulous; corolla pink to magenta, 7-9 mm. in total length, the lobes rounded and spreading, 2-2.5 mm. long and 2.3-3.2 mm. broad; nutlets to 1.4 mm. long and 0.9 mm. thick, dusky, back convex, papillate. Usually on or about exposures of Upper Cretaceous beds and most commonly on silty or only moderately rocky soils in the Trans-Pecos, Apr.-June; from Tex., s. and s.e. across Coah.

3a. *Coldenia mexicana* var. *tomentosa* (Wats.) I. M. Johnst. Usually in areas of Upper Cretaceous beds and most frequently on rocky soils w. of the lower Pecos in s. Val Verde and Terrell cos., Apr.-July; s. through Coah.

4. *Coldenia gossypina* (Woot & Standl.) I. M. Johnst. Plant forming mats 2-4 dm. broad from a woody taproot, the young branchlets densely villulose; leaves clustered mostly on very short branchlets along the main stems and branches, oblong or oblanceolate, to 8 mm. long and 2 mm. broad, in age detaching from the persistent petiole; upper leaf surface cinereous, bearing spreading pungent bristles arising from a thickened mineralized base and also a fine villulose indument composed of small pallid slender hairs; lower leaf surface only partially covered by the loosely revolute leaf margins, villulose and usually retrorsely so along the lower half of the prominent midrib; calyx sessile, at anthesis 3-3.5 mm. long, permanently affixed, the lobes lanceolate, densely short-villose and hispidulous; corolla pink to magenta, 7-8 mm. in total length, the lobes rounded, up to 2 mm. long and 3 mm. broad; nutlets dusky, ovoid, to 1.2 mm. long and 0.8 mm. broad below the middle, covered with grayish vesicular papillae of unequal size. Usually on gypseous soils in the Trans-Pecos and along the Rio Grande n.w. to El Paso, Apr.-July; Tex., N.M., Chih. and Coah.

5. *Coldenia hispidissima* (T. & G.) Gray. Plants forming matted growths 2-4 dm. in diameter spreading from a woody taproot, the younger branchlets villulose-hispidulous with minute spreading or retrorse hairs and sometimes with pungent bristles; leaves clustered mostly on very short branchlets along the main stems, usually linear but rarely ovate or elliptic, to 1 cm. long and 1 mm. wide, usually distinctly narrower than the

indurated petiole base, the upper surface usually green and bearing scattered spreading pungent hairs that arise from bulbous or discoid bases; calyx sessile, broadly and permanently attached in a leaf axil, at anthesis about 3 mm. long; calyx lobes narrowly lanceolate, villous-ciliate below the middle, frequently terminated by a stiff bristle, the back minutely hispidulous, at maturity with a thickened slightly prominent midrib; corolla usually pink, about 7.5 mm. in total length, the lobes rounded and spreading, about 2 mm. long and 3 mm. broad; mericarps ovoid, usually only one or two maturing, to 1.4 mm. long and 1 mm. broad below the middle, papillate or vesicular-papillate. Usually on gypsum or strongly gypseous soils in the Trans-Pecos and e. of the Pecos River through Loving, Ward and Crane cos. to Ector and Irion cos., May-Aug.; also widely distributed in N.M.

4. TOURNEFORTIA L.

A genus of about 150 species composed chiefly of scandent shrubs and occurring mainly in the American tropics.

1. *Tournefortia volubilis* L. Twining vine; stems slender, frutescent, sparsely and minutely strigose or tomentulose when young; leaves lanceolate to ovate or elliptic, pinnately veined, to 9 cm. long and 4 cm. broad, with a slender petiole 5-13 mm. long, base acute to rounded, apex acute or attenuate, above glabrous or minutely strigose, below paler and more densely hairy; inflorescence terminal or not infrequently lateral, bearing 3 to 10 very slender scorpioid cymes 3-8 cm. long; calyx 5-fid, about 2 mm. long, borne on a very short stout pedicel, the lobes cuneate; calyx in fruit with much-thickened pedicels and slightly enlarged lobes, embracing base of drupe, persistent, not falling with fruit; corolla greenish-yellow, the tube 2-3 mm. long, strigose outside, the lobes linear, 1-2 mm. long, spreading, broad only at the base; stamens included; fruit a drupe; exocarp white, with 1 to 3 black spots on the side, blackening on drying; endocarp usually roughly 2- or 3-lobed (2- or 3-seeded) or simple and 1-seeded. In open forests climbing on trees and in arroyos in Cameron Co., Feb.-July; from n. S.A., n. through the W.I., C.A. and Mex. to Fla. and southernmost Tex.

A very variable species in leaf shape and indument.

5. HELIOTROPIMUM L.

TURNSOLE. HELIOTROPE

Annual or perennial, herbaceous or more or less shrubby plants; leaves small to large, sessile or petiolate; cymes unilateral and generally distinctly scorpioid, with or without bracts; corolla white, yellow or purple, variable in form, throat frequently pubescent inside; anthers included, filaments extremely short; style present or absent; stigma usually frustrumlike or conic, mostly sterile, receptive only in a band around the base; fruit dry, at maturity breaking up into 4 1-seeded or 2 2-seeded mericarps; seeds usually with a thin endosperm.

About 250 species widely represented in the warmer parts of the world. The species are particularly numerous in arid regions.

1. Mature fruit breaking up to form 2 mericarps, each one 2-seeded; leaves evidently veined; cymes bractless (2)

1. Mature fruit breaking up into 4 1-seeded mericarps; leaves may or may not be evidently veined; cymes with or without bracts (5)

2(1). Stems and younger parts glanduliferous; corolla tube very hairy inside; an escape from gardens1. *H. amplexicaule*.

2. Stems and younger parts not glanduliferous; native species (3)

3(2). Mericarps with two seminiferous cells and no sterile ones, the surface warty with pale minute vesicular epidermal appendages; corolla tube sparsely but distinctly strigose inside; plant erect, fruticulose, from a taproot2. *H. angiospermum*.

3. Mericarps with two seminiferous cells and one or more sterile cells, the surface densely fine hairy, more or less velvety; corolla tube glabrous inside; plants herbaceous, rhizomatous, the stems spreading (4)

- 4(3). Plant with simple hairs; leaf blades ovate to broadly lanceolate or somewhat cordate, 3-6 cm. long, 1-4 cm. wide; veins numerous, evident, branched; fruit with a corky mesocarp; each mericarp with a single sterile cell 3. *H. molle*.
4. Plant with malpighiaceae hairs on stems and leaves; leaf blades lanceolate, 2-4.5 cm. long, rarely more than 1 cm. wide; veins few or none, obscure, always simple; fruit lacking a corky mesocarp; each mericarp with 3 sterile cells of which the 2 larger are partially filled with corky tissue 4. *H. glabriusculum*.
- 5(1). Plant very succulent, glabrous, usually glaucous (6)
5. Plant not succulent, hairy, never glaucous (7)
- 6(5). Corolla white, the limb 1.5-3 mm. in diameter; leaves 8 mm. wide or less 5. *H. curassavicum* var. *curassavicum*.
6. Corolla white and often purple-tinged at throat, the limb 5-10 mm. in diameter; leaves to 17 mm. wide 5. *H. curassavicum* var. *obovatum*.
- 7(5). Plant perennial (Doubtful cases should be keyed under both alternatives) (8)
7. Plant annual (10)
- 8(7). Corolla greenish-yellow, tubular, the lobes elongate, attenuate, acute; stigmatic head elongate, cylindric; anthers not coherent; plant bushy, fruticose; inflorescence bractless 6. *H. Torreyi*.
8. Corolla white, funnelform, the lobes broad; stigmatic head short; anthers with tips coherent; plants not noticeably fruticose and bushy (9)
- 9(8). Plants rhizomatous, the parts above ground renewed annually; inflorescence with a few inconspicuous bracts; leaves green, 10-24 mm. long, 2-5 mm. wide 7. *H. Greggii*.
9. Plants with a prostrate shrubby caudex; inflorescence abundantly leafy-bracted; leaves small, usually gray, very numerous and usually crowded and overlapping, usually 3-5 mm. long and 0.7-1 mm. wide 8. *H. confertifolium*.
- 10(7). Cymes bractless; leaves usually with evident veins (11)
10. Cymes with leafy bracts; leaves veinless or the veins few and obscure (13)
- 11(10). Throat of corolla pubescent just below the limb; corolla lobes narrow and acute; mericarps coarsely strigose 9. *H. procumbens*.
11. Throat of corolla glabrous; the shallow corolla lobes broad and rounded; mericarps glabrous or at most very finely strigose or puberulent (12)
- 12(11). Fruit 2-lobed, with lobes widely divergent; mericarps smooth, strongly ribbed 10. *H. indicum*.
12. Fruit 4-lobed, the lobes not widely divergent; mericarps strongly tuberculate 11. *H. europaeum*.
- 13(10). Corolla lobes longer than broad and narrowed below the middle; fruiting calyx with slender pedicels 2-10 mm. long; stigmatic head slender and elongate, borne on a very short style 12. *H. tenellum*.
13. Corolla lobes broader than long or only obscurely developed; fruiting calyx pedicels short and stout or none, usually evidently less than 5 mm. long; stigmatic head short and stout (14)
- 14(13). Fruit not compressed laterally, radially 4-lobed; style stout, 0.6-0.9 mm. long; stigmatic head lacking a conspicuous terminal tuft of hairs; southern Texas 13. *H. texanum*.
14. Fruit strongly compressed laterally, 2-lobed; styles slender and elongate, 2.5-4 mm. long; stigma bearing a conspicuous terminal tuft of hairs (15)
- 15(14). Corolla limb 15-20 mm. in diameter, pentangular in outline, obscurely and very broadly if at all lobed; flowers apparently scattered along the elongate leafy stems 14. *H. convolvulaceum*.

15. Corolla limb 6-17 mm. in diameter, star-shaped, the lobes triangular and acute; flower and fruit crowded into readily delimited racemose inflorescences 5-10 cm. long, forming the outer half of the leafy branchlets produced by the main stem and its primary branches; coastal plain of southern Texas . . 15. *H. racemosum*.

1. *Heliotropium amplexicaule* Vahl. Perennial from a deep woody root, 2-5 dm. tall, more or less abundantly and minutely pubescent and sometimes sparsely villous or hispid; stems usually several from the root, ascending or decumbent, loosely and ascendingly branched; leaves oblong to oblanceolate, to 9 cm. long and 18 mm. wide, acute to rounded at apex; inflorescence terminal on the leafy branches or lateral and extra-axillary, forked, consisting of a cluster of 2 to 5 scorpioid cymes; peduncle naked, 1-10 cm. long; calyx sessile, evidently shorter than corolla tube, usually glandular-pubescent, persistent, the lobes nearly equal, linear to lanceolate, at anthesis 2.5-5 mm. long, spreading after fall of fruit; corolla funnelform, blue or purple or rarely white, the limb 4-8 mm. in diameter, the lobes short and broad, the tube well-developed, about 5 mm. long; fruit glabrous, 1.5-2.5 mm. high, 2-3 mm. long, slightly compressed laterally. Frequently cult., occurring erratically in fields and waste places, Apr.-Aug.; nat. of Arg. and Urug., now widely adv. and escaped.

2. *Heliotropium angiospermum* Murr. A loosely branching coarse weedy annual or short-lived perennial, becoming somewhat fruticose at maturity, erect or decumbent, 3-8 dm. tall; stems loosely and ascendingly branched above the base, moderately or even sparingly hispidulous; leaves mostly alternate, frequently dotted with very minute pale mineralized warts, ovate to broadly lanceolate, to 6 cm. long and 25 mm. wide, above sparingly hispidulous, below paler with hairs confined mostly to the midrib and veins, apex acute, base acute to rounded, abruptly contracted into a petiole 2-9 mm. long; inflorescence scorpioid, simple or geminate, evidently pedunculate, bearing crowded 2-ranked flowers and fruits, terminal on the leafy shoot or borne extra-axillary and lateral along the leafy shoot, in maturity slender and elongate, to 15 cm. long, stiff and erect, carried on a naked peduncle 1-5 cm. long; calyx sessile, the lobes equal or nearly so, lanceolate to lance-oblong, usually 1.5-2 mm. long, only moderately accrescent in fruit; corolla white, the limb 2-3 mm. broad; fruit strongly compressed laterally, usually 1.5-2 mm. high, 2-3 mm. long. In sandy and gravelly soils in chaparral, thickets and open fields in s. Tex., throughout year; from Bol. and n. Chile, n. through C.A. and the W.I. to Fla. and s. Tex.

3. *Heliotropium molle* (Torr.) I. M. Johnst. Low perennial, occurring in colonies; stems decumbent, loosely branched, 1-3 dm. long, developing anew each year from the root or from a small weakly developed caudex, gray or tan, appressed hispid-villose; leaves numerous, with a petiole 1-3.5 cm. long, densely hispid-villose with appressed hairs, the margin moderately to coarsely crenate and visually crisped, apex acute to obtusish, base usually broadly asymmetric; inflorescence terminal on the leafy stems or opposite leaves, consisting of 2 or 3 densely flowered scorpioid cymes borne at the apex of a naked peduncle 2-4 cm. long; calyx subsessile, at anthesis 2-3.5 mm. long, the lobes at maturity 3-5 mm. long, linear-lanceolate, hairy, embracing the fruit; corolla white or slightly stained with purplish, in throat yellow, total length 6-10 mm. long, funnelform, the lobes rounded and separated by well-developed plaited inflexed sinuses; fruit dry, ovoid-globose, 3.5-4 mm. high, dorsiventrally 4.5-5 mm. long. Growing in valley soils, on flats, usually in places where water collects and stands for a short time after rain storms, and most commonly in places in the vic. of Upper Cretaceous outcrops, in Tex. only from Brewster Co. and from along the Rio Grande in w. Presidio Co., Apr.-Sept.; also Coah. and Chih.

It is worthy of note that another Texan species of this genus, which also grows on clay flats in places where there is a shallow pooling of water after rains, likewise has what appears to be buoyant corky tissue developed in the mericarp. This corky tissue in the mericarps of *H. molle* and *H. glabriusculum* may be useful in the dissemination of the fruit by water and may be adaptations for the specialized habitat these plants affect.

4. *Heliotropium glabriusculum* (Torr.) Gray. COLA DE ALACRÁN. Perennial, forming colonies; stems usually several, springing from the root crown or from a small caudex, renewed annually, grayish strigose with the hairs all malpighiaceous, loosely decumbent

and branched, 1-3 dm. long; leaves numerous, green, minutely and abundantly dotted, firm, usually glabrous except on the petiole and along the prominent midrib on the lower surface, the margin weakly revolute and usually more or less evidently crisped, apex acute, base narrowed into a petiole 1-6 mm. long; inflorescence terminal on the leafy stems and branches, consisting of 2 or sometimes 3 densely flowered scorpioid cymes borne clustered on a naked peduncle 1-3 cm. long; flowers fragrant; calyx sessile, 2-3 mm. long, the lobes lanceolate, attenuate, moderately unequal, with a few malpighiaceus hairs down the middle line and sparingly ciliate with simple hairs on the margin; corolla white with a greenish-yellow throat when fresh, becoming cream-colored with a purplish throat when dry, 4-5.5 mm. long, the sinus between the short corolla lobes simple, closed with neither plaits nor lobules; fruit grayish from a dense pubescence of minute simple hairs. *Heliohytum glabriusculum* Torr. Growing on valley soils, usually on clay in limestone areas, and particularly in places subjected to temporary flooding after rain storms, in Tex. it has been collected most frequently in s. Brewster and s. Pecos cos., but it is also known from Val Verde, Maverick, Webb and McMullen cos., May-Aug.; from Tex. s. to e. Dgo. and n. Zac.

The malpighiaceus hairs distinguish *H. glabriusculum* from all other Texan Boraginaceae.

5. *Heliotropium curassavicum* L. var. *curassavicum*. SEASIDE HELIOTROPE, COLA DE MICO. Perennial, usually with a deep rhizome; stems prostrate or laxly decumbent, rubbery, to 4 dm. long and 5 mm. thick, ascendingly branched; leaves oblanceolate, often narrowly so, thick and juicy, strongly compressed, to 4 cm. long and 8 mm. wide, the apex obtuse or rounded; inflorescence terminal or extra-axillary and lateral along the leafy stems, single or paired or rarely ternate, densely flowered, entirely bractless, scorpioid cymes, in fruit elongating, becoming as much as 1 dm. long and the rachis usually more or less broadened and flattened; calyx sessile or nearly so, lobed almost to the base, the lobes lanceolate or oblong, equal or nearly so, fleshy, at anthesis 1-1.4 mm. long, moderately accrescent in fruit; corolla white, small, 1.2-3.5 mm. long, entirely glabrous, the lobes rounded, the tube shortly surpassed by the calyx lobes; fruit 4-lobed, 2-2.5 mm. high, 2-3 mm. thick, obscurely compressed laterally, embraced by the somewhat accrescent calyx lobes, smooth and glabrous; mericarps bearing a thick layer of firm vesicular exocarp which apparently functions as a float-organ in water dissemination. In sandy soil along beaches, about ponds, saline flats and similar areas throughout Tex., most of the year; from Fla., n. to Del., w. to Okla., Tex. and N.M., s. in the W.I., Mex. and C.A. to Surinam and Col. and thence s. along the Pac. Coast of S.A. to Chile and Arg.; introd. in s. Eur.

Var. *obovatum* DC. The corolla limb of var. *obovatum* is 5-10 mm. wide, at most only purplish-tinged at the throat, and the fruit is 2.5 mm. wide. The oblanceolate to spatulate leaves are also to 2 cm. wide. *H. spathulatum* Rydb. Rare, Dallam Co. in the Plains Country, on the edge of a large old buffalo wallow (playa lake) e. of Texpline, June-July; w. U.S.

6. *Heliotropium Torreyi* I. M. Johnst. Small shrub, 1-5 dm. tall, gray-green, usually stiff and bushy; stems slender, ascendingly branched, frutescent; branchlets strigose, frequently densely so and pallid; leaves abundant, linear, to 3 cm. long and 3 mm. wide, sparsely strigose, acute, scattered along the branchlets or sometimes in axillary fascicles, subsessile or with a petiole less than 1 mm. long, the margins revolute; racemose cymes terminal on the leafy branchlets, slender, 1-2 or rarely as much as 1 dm. long; calyx lobes linear, strigose, to 5 mm. long and 0.4 mm. wide, acute, moderately unequal; tubular portion of corolla about 4 mm. long, not surpassing the calyx, densely strigose outside, glabrous inside, with an annular linear constriction just above base, the throat with weak pleats above the middle, the limb 3-4 mm. in diameter; fruit 3 mm. thick, 2 mm. high. *H. angustifolium* Torr., non Raf. Mostly on open or brushy limestone slopes or mesas, in the Trans-Pecos, the Edwards Plateau, along the Balcones Escarpment, from Presidio and Pecos cos. e. in cos. along the Rio Grande to Edwards, Kinney and Uvalde cos., also on limestone and caliche beds from McMullen and Bee cos. through Duval, Jim Wells and Jim Hogg to Hidalgo Co., Apr.-Nov.; from Tex. s. in N.L., Coah. and e. Chih. to S.L.P.

Said to be a good browse for sheep.

7. *Heliotropium Greggii* Torr. Plant from a deep rhizome, strigose, pale-green; stems usually numerous, prostrate or loosely decumbent, ascendingly branched, leafy, to 15 cm. long; leaves numerous, thickish, lanceolate to linear, sessile or with petioles to 3 mm. long, midrib prominent but veins absent, the margin revolute; inflorescence at first glomerate and then elongating into a loose racemose cyme to 5 cm. long, commonly 5- to 10-flowered; calyx lobes about equal, 2-3 mm. long, lanceolate; corolla white with a yellow throat, fragrant, the limb 7-12 mm. broad, shallowly lobed with 5 broad rounded principal lobes and (alternating with these) 5 smaller somewhat triangular incurved lobes, the throat with hairy inflexed plaits, the tube inside bearing an inconspicuous nectariferous ring about 0.5 mm. above the base; fruit very hairy, about 3 mm. thick and 1.5 mm. high. Usually forming colonies in places where water collects temporarily, frequent along roadside shoulders and ditches, in sand, gravel or on clay flats, lacking in volcanic areas, frequent and widely distributed in the Trans-Pecos and also e. in Loving, Ward, Crane and Upton cos., with outlying stations in Knox and Medina cos., Apr.-Sept.; N.M., Tex., Coah., Chih., Dgo. and Zac.

8. *Heliotropium confertifolium* (Torr.) Gray. Plant usually less than 1 dm. tall, with a woody taproot, the herbage grayish or somewhat silvery, clad with fine abundant, pale, loosely and antrorsely appressed hairs that are intermixed with some coarser spreading hairs, forming rounded masses of crowded leafy stems and at times cespitose or even pulvinate; caudex dichotomously branched, sometimes as much as 4 cm. thick, annually expanding by the addition of generous portions of some of the leaf-bearing stems of the previous season, older branches of the caudex decorticated and becoming rough and brown and its oldest principal branches as much as 8 mm. thick; leaves small, alternate or the lowermost on the shoot opposite, usually bunched and more or less fasciculate at the apex of the shoot, several to many times longer than the adjoining stem internodes, strictly ascending and usually somewhat imbricate, strigose and commonly bearing also some long spreading hairs, narrowly lanceolate; inflorescence terminal on the stems and branches, simple, 2- to 10-flowered, usually glomerate, foliaceous, 2-4 mm. long; calyx subsessile, densely strigose, 3-4 mm. long, the lobes moderately unequal, linear to linear-oblong, foliaceous; corolla white with a yellow throat, funnellform, 5-8 mm. in length, densely strigose outside, the limb 5-8 mm. in diameter, the narrowed lobes separated by a broad but strongly plaited sinus, the throat puberulent inside, with inflexed puberulent plaits below each sinus; fruit about 1.5 mm. thick and 1 mm. high. In w. Tex. usually associated with Upper Cretaceous limestones perhaps because of the trace of gypsum they contain, in s. Tex. in areas where mildly gypseous soils occur, ranging from w. Pecos Co. and the Big Bend s.e. in cos. fronting on the Rio Grande to Webb, Zapata, Starr and Hidalgo cos., also from Jim Wells and Jim Hogg cos., Mar.-Oct.; also n. Mex.

9. *Heliotropium procumbens* Mill. Plant erect to loosely decumbent, 1-5 dm. tall, moderately to abundantly strigose or appressed hispid-villose, pale-green or somewhat cinereous or even canescent; stems one to several, when single usually loosely and ascendingly branched above the base; leaves numerous, with petioles to 1 cm. long, narrowly oblanceolate to elliptic, plane or more or less evidently revolute, to 4 cm. long and 2 cm. wide, apex usually acute, base cuneate, upper and lower surfaces consimilar in coloration and indument; inflorescence consisting of usually numerous scorpioid cymes; cymes solitary or geminate, densely flowered, borne terminal or extra-axillary along the leafy stems, 3-10 cm. long, on naked peduncles 1-3 cm. long; calyx at anthesis 1-1.2 mm. long, the lobes unequal, especially in width, linear to broadly lanceolate, as long as or slightly longer than the corolla tube, at maturity nearly doubling in size and becoming more unequal; corolla white, 1.5-3 mm. long, the tube sparsely strigose outside, the limb 2-3 mm. broad; fruit 1-2 mm. thick, 1-2 mm. high. A weedy species, usually growing in damp situations or on land subject to flooding, n. to Jefferson, Hays, Bexar and Brewster cos., Apr.-Nov.; in Fla., La. and Tex., mostly on the Coastal Plain, widely distributed in the W.I., C.A. and trop. S.A.

10. *Heliotropium indicum* L. TURNSOLE, ALACRANCILLO. Coarse annual herb, villose or hispid or hispidulous, to 1 m. tall; stems loosely branched, leafy, frequently fistulose; leaves with a petiole 4-10 cm. long, ovate to elliptic, drying thin, to 15 cm. long and 1 dm. wide, the margin repand or undulate, apex acute, base obliquely acute to obtuse or

subcordate; inflorescence a simple, very elongating scorpioid cyme to 3 dm. long, bearing two ranks of crowded flowers and fruits; calyx broadly sessile, 1.5-2 mm. long, the lobes linear or linear-lanceolate, unequal; corolla blue or violet (or rarely white), puberulent or strigose outside, the limb to 4.5 mm. in diameter, the tube elongate, evidently surpassing the calyx, usually about 3 mm. long, constricted at the throat; fruit miter-shaped, glabrous or puberulent. Along river banks and bottoms, ditches, lake shores and along creeks, e. half of Tex. w. to Dallas, Bexar and Hidalgo cos., June-Oct.; widely distributed in the warmer parts of Am. from n. Arg. to s. U.S.; also in the trop. of the Old World; probably a nat. of Am.

11. *Heliotropium europaeum* L. Erect or decumbent herb, 1-5 dm. tall, loosely and ascendingly branched; stems minutely and antrorsely hairy; leaves densely and minutely hairy, usually somewhat velvety, the hairs with thickened bulbous bases, elliptic to ovate or obovate, to 5 cm. long and 3 cm. wide, apex obtuse, base abruptly contracted into a slender petiole to 25 mm. long; inflorescence a simple or forked scorpioid cyme, becoming as much as 1 dm. long at maturity, borne on a naked peduncle 1-5 cm. long, terminal on the leafy branches or extra-axillary along their length; calyx sessile, at anthesis about 2 mm. long, hairy, the lobes subequal, lanceolate, persistent and spreading or reflexed after the fall of the mericarps; corolla white or somewhat bluish, yellow in the throat, minutely hairy outside, about 3.5 mm. long, the limb 2-3.5 mm. broad, with short rounded ascending lobes and strong reflexed pleats at and below the sinus. Rare (collected once in Hays Co.), introd. weedy species (seen from N.J., Pa., Va., Fla., Ga., Ala., Miss., La. and Tex.); nat. of s. and cen. Eur., N. Afr., and e. to the Caucasus and Iran.

12. *Heliotropium tenellum* (Nutt.) Torr. Plant erect, 2-5 dm. tall, usually simple below and abundantly and loosely branched above or about the middle; stems and branches slender, minutely strigose; leaves linear, to 5 cm. long and 5 mm. wide, narrowed toward both ends, minutely strigose, the margins revolute; flowers borne in slender, elongate, very loose terminal racemose cymes; calyx lobes extremely unequal, linear, with revolute margins, foliaceous, longest one about 4 mm. long at anthesis, becoming at least 5 mm. long and sometimes as much as 1 cm. long at maturity, twice as long as the shortest lobe; corolla funnelliform, white with a yellow throat, 6 mm. long, the limb 5-6 mm. in diameter, deeply lobed (the lobes obovate to elliptic), the tube glabrous inside, upper portion narrowed with inflexed pleats; fruit 3 mm. broad, 1.5 mm. high. *H. Nuttallii* House, *Lithospermum tenellum* Nutt., *L. gracile* Raf. On rocky or gravelly soils in the open or in cedar-oak woods or brushlands, mostly limestone, in the e. two thirds of Tex., May-Oct.; from Ky., Mo. and Kan. s. to Ga., Ala. and Coah.

13. *Heliotropium texanum* I. M. Johnst. Plant 1-4.5 dm. tall, simple and erect or with few to numerous ascending leafy stems; stems usually scantily branched, antrorsely short-strigose; leaves firm, thickish, rather bright-green, mostly alternate, strigose, oblanceolate to broadly lanceolate, to 3 cm. long and 9 mm. wide, apex acute, base narrowing into a slender petiole 2-5 mm. long, the margin usually revolute; inflorescence terminal on the leafy stems and branches, scorpioid, bearing numerous crowded 2-ranked flowers; calyx lobes very unequal with 2 lobes evidently longer and broader than the other three, the largest lobe oblong at anthesis and to 3.5 mm. long and 1.5 mm. wide, becoming slightly larger in fruit; corolla white with a yellow throat, sparsely strigose outside, funnelliform, 5-10 mm. long, the limb to 12 mm. broad; fruit hispidulous, 2 mm. thick, 1 mm. high. In sandy soils of the Rio Grande Plains to Atascosa Co., June-Oct.; Tex. s. to S.L.P.

14. *Heliotropium convolvulaceum* (Nutt.) Gray. Plant 1-4 dm. tall; stems at first usually simple and erect and later developing elongate ascending branches, less commonly becoming widely branched and sprawling or decumbent, strigose, the younger parts densely so and cinereous; leaves shortly petiolate, numerous, firm, appressed-strigose, the hairs arising from mineralized bulbous or discoid bases, lanceolate to ovate, to 4 cm. long and 15 mm. wide, the margin flat or very narrowly revolute, apex acute, base cuneate to rounded; flowers extra-axillary; calyx at anthesis 4-6 mm. long, becoming 6-8 mm. at maturity, the lobes linear-lanceolate or subulate-linear, unequal, with the two largest lobes evidently broader and 0.5-1 mm. longer than the shortest lobe; corolla pure-white with a yellow throat, fragrant, opening during morning and evening, the

limb widely funnellform and 15-22 mm. broad, the tube 8-11 mm. long, strigose outside, inflexures in the throat alternating with vertical bands of hairs borne along the principal veins; fruit 3-4 mm. long, 2-2.5 mm. thick, and 2-2.5 mm. high. In dunes and sandy places in w. Tex. and extending e. along the Rio Grande Valley to Grayson Co. and along the Brazos Valley to McLennan Co., June-Oct.; from Neb. and Wyo. s. to s. Nev., Ariz., Tex. and n. Chih.

15. *Heliotropium racemosum* (Rose & Standl.) I. M. Johnst. Plant 1-4 dm. tall; stems at first simple and erect but later developing elongate branches and usually becoming sprawling or decumbent, coarsely strigose, the young parts densely so; leaves shortly petiolate, numerous, firm, strigose (the hairs stiff, straight and closely appressed and parted left and right on either side of the midrib, their bases bulbous or discoid), lanceolate or rarely oblong to elliptic, to 4 cm. long and 11 mm. wide, apex acute; flowers and fruit extra-axillary; calyx strigose, 4-5 mm. long in anthesis and becoming 5-6 mm. long in fruit, the lobes unequal, linear to linear-lanceolate; corolla pure-white, fragrant, usually opening at night or on cloudy days, the limb when expanded funnellform and 6-17 mm. broad, tubular portion of corolla 4-8 mm. long, strigose outside, the inflexed fold from the sinus of the corolla limb extending down into the mouth of the corolla and continuing only as very weak inflexures in the upper half of the throat; fruit usually 2 mm. high, 3-3.5 mm. long, and about 2 mm. thick at maturity. *H. convolvulaceum* var. *racemosum* (Rose & Standl.) I. M. Johnst. Sandy places in the Coastal Plain of s. Tex., s. and s.e. of San Antonio; also known from Travis Co., May-Oct.; endemic.

Closely related to the more northern and western *H. convolvulaceum*, and differing only in its smaller flowers, its star-shaped corolla limb with acute lobes, and its denser and more readily delimited inflorescences.

6. OMPHALODES MILL.

About 28 species, mostly in the Mediterranean region and Asia.

1. *Omphalodes aliena* Gray. Weak decumbent annual; stems loosely few-branched, very slender, 1 mm. or less thick, to about 6 dm. long, sparingly hispidulous or strigose, ascending mostly from near the base of plant, soon spreading; leaves few, long-petioled, alternate, borne mostly below the middle of the plant, ovate, cordate at base, apiculate, 1-4 cm. long and about as wide, sparsely hispidulous, drying thin; petiole 1-4 cm. long; inflorescence slender, racemose, terminal, at maturity very elongate and remotely flowered, bractless or rarely with a single small foliaceous bract; flowers with slender pedicels at anthesis 1-5 mm. long, at maturity to 3 cm. long; calyx lobes 5, lanceolate, strigose, 1.5 mm. long at anthesis, acute, doubling in size at maturity; corolla rotate, sky-blue or sometimes white, yellow in the throat, the tube very short, the limb 8-10 mm. in diameter; faucal appendages well-developed, trapeziform, puberulent, protrudent; mericarps 4, depressed, forming a pyramid, attached to the small carpophore by their inner faces, their margins broad and thin, entire to serrate or ciliate, reflexed over the back of the mericarps so as to form on each a small nearly closed cell opening outwards by a small hole, the mericarps smooth on the back. Limestone areas in s. Val Verde, Terrell, Presidio and Brewster cos., Mar.-Apr.; also n. Mex.

7. CYNOGLOSSUM L.

HOUND'S TONGUE. BEGGAR'S-LICE

Biennial or perennial or rarely annual plants; leaves alternate, the basal ones long-stalked; racemes elongating, usually ebracteate, rarely bracted at the base; calyx cut to beyond the middle, somewhat accrescent at maturity and spreading or reflexed; corolla cylindrical or funnellform; lobes broad, spreading, imbricate; throat with trapeziform, oblong or sublunate appendages; stamens included, affixed in the tube; filaments short; anthers oblong or elliptic; ovules 4; mericarps 4, depressed-ovoid or orbicular, glochidiate, ascending or divaricate, back flat or convex, frequently with an elevated margin, attached by a small or large medial to apical scar to a convex or pyramidal gynobase and frequently with a free subulate prolongation decurrent on the short entire style.

A cosmopolitan genus of about 55 species.

1. Mericarps 5.5-7 mm. long; plant perennial 1. *C. virginianum*.
 1. Mericarps 2.5-4 mm. long; plant biennial 2. *C. zeylanicum*.

1. *Cynoglossum virginianum* L. WILD COMFREY. Plant erect, the simple stems conspicuously hirsute, 3-8 dm. tall; basal leaves elliptic-oblong, tapering at base and decurrent upon the long petiole, 1-2 dm. long; cauline leaves sessile, progressively smaller, some broadly clasping at base, some often narrowed below and more or less expanded at the very base; racemes 1 to 4, usually 3, at maturity 1-2 dm. long, terminating a long, erect, terminal peduncle; calyx at anthesis 3-4 mm. long, the lobes to 2.5 mm. long in fruit; corolla blue to white, the tube 1.5-3 mm. long, the broadly rounded lobes more or less overlapping; fruiting pedicels 5-15 mm. long, recurved; mericarps globose-obovoid, uniformly bristly over the exterior surface; style obscured by the mericarps, 1-2 mm. long. Upland deciduous woods in e. Tex., Mar.-Apr.; from s. N.E. s. to Fla. and w. to e. Tex.

2. *Cynoglossum zeylanicum* (Vahl) Thunb. Plant erect, depressed-strigose, the stems without spreading or lax hairs, 3-9 dm. tall; radical leaves large, long-petioled, persistent at the time of flowering; cauline leaves oblong, sessile, entire, softly hairy, to 1 dm. long and 25 mm. wide, acute, frequently subdecurent, glabrous or very minutely but scarcely scabrous on the upper surface, the nerves beneath often prominent, the upper leaves with a narrowly cuneate base; racemes furcate, the branches long-fulvous toward their tips; pedicels of lower flowers often 3-6 mm. long; calyx lobes ovate, in fruit often 3 mm. long and broadly oblong; corolla small, 4-5 mm. long; mericarps 2.5-4 mm. long, outer face of mericarps 3 mm. with no distinct medial line and with scattered glochidia often not much shorter than the marginal ones; carpophore linear, hardly conical at the base. Rare in e. Tex., May; nat. of India, Ceylon and Malaysia, introd. in various parts of the world.

The silky indumentum and tawny young racemes are distinctive.

8. LAPPULA FABR. STICKSEED

Small annual or rarely perennial herbs; leaves alternate, usually narrow, firm and veinless; flowers small, blue or white, on usually erect pedicels or rarely sessile, in bracted racemes; calyx 5-parted into spreading lanceolate lobes; corolla with a rather short tube; lobes rounded, ascending, imbricate; throat closed by intruded appendages; stamens affixed in the tube, included; filaments slender, short; anthers oblong, obtuse; style short, surmounting the subulate-columnar gynobase, commonly surpassing the mature mericarps; stigma subcapitate; ovules 4; mericarps 4, erect, smooth or verrucose, narrowly but firmly attached to a slender elongate gynobase along the length of the well-developed ventral keel, back angulate or margined by a single row of prickles which by confluence frequently form a winglike or cupulate border.

A difficult genus whose species are mainly critical ones, being largely separated by technical characters of the fruit, such as size and form of the mericarps, their surface and the characters of the dorsal margin. About 50 species in Eurasia, Australia and America.

1. Mericarps with marginal prickles in at least two rows . . 1. *L. echinata*.
 1. Mericarps with marginal prickles definitely in a single row (2)
 2(1). Marginal prickles distinct to base or nearly so, not confluent to form a cupulate structure 2. *L. Redowskii*.
 2. Marginal prickles confluent, forming a conspicuous smooth cupulate structure on back of some or all the mericarps 3. *L. texana*.

1. *Lappula echinata* Gilib. Erect annual, 1.5-8 dm. tall, the stems simple to freely branched, harshly appressed-pubescent and canescent; leaves linear to linear-oblong or the lowest oblanceolate, acute to obtuse, narrowed to a sessile base, closely ascending, 2-5 cm. long, roughly pubescent like the stem, passing above into the linear or lanceolate bracts of the usually numerous racemes; pedicels 1-3 mm. long; calyx lobes broadly linear, appressed-bristly, in fruit spreading, 2.5-3 mm. long; corolla bright-blue, the limb 2-4 mm. broad, the tube surpassing the calyx; mericarps 3-4 mm. long, sharply verrucose or muricate dorsally, with 2 marginal rows of long slender bristles not confluent at base, these sometimes irregularly distributed over most of the back. *L. Lappula* (L.) Karst.

Occasionally in waste places and cult. ground; nat. of Euras.; widespread as a weed in n. U.S. and Can. Reported from Texas 65 years ago but we have seen no specimens.

2. *Lappula Redowskii* (Hornem.) Greene. Annual, 1-5 dm. tall, usually somewhat cinereous, hispid-villose, the hairs spreading or loosely ascending; stems usually single but not infrequently with several minor stems springing from the base of the major stem; leaves narrowly oblanceolate to spatulate, the basal leaves to 5 cm. long and 8 mm. wide, clustered into a rosette which usually persists (at least in the dried state) until some time after anthesis, the stem leaves gradually reduced in size upwards along the stem; cymes racemose, terminating the stems and branches, abundantly and conspicuously bracted, becoming loosely flowered and to 3 dm. long at maturity; calyx at anthesis 2-3 mm. long, the mature calyx with unequal linear or lanceolate usually spreading lobes 3-5 mm. long; pedicels of fruiting calyx stiff, usually strictly ascending, 1-3 mm. long; corolla blue, surpassing the calyx 1 mm. or less, funnellform, the tube cylindric, about 1.2 mm. long; faucal appendages well-developed, borne at the base of the throat, intrusive, invaginate. Widely distributed in cen. and w. Tex., usually in sunny places in disturbed soils, Mar.-May; throughout w. U.S., in Arg. and Asia.

3. *Lappula texana* (Scheele) Britt. Annual, 1-4 dm. tall, hispid-villose, the pale hairs very slender and loosely ascending; stems single or several to many, simple and branched only above the middle; leaves narrowly oblanceolate or spatulate, rounded to obtuse at apex, the basal leaves crowded into a rosette which persists at least in a dried state for some time after anthesis, to 8 cm. long and 5 mm. wide, the cauline leaves gradually smaller up the stem; cymes racemose, solitary at the ends of the stems and its branches, becoming loosely flowered and 1-3 dm. long at maturity; calyx at anthesis 2-3 mm. long, at full maturity its lobes usually spreading, unequal, linear to lanceolate, 3-5 mm. long; pedicel becoming 1-4 mm. long, stiff, usually strictly ascending; corolla blue, funnellform, commonly 3 mm. long, surpassing the calyx lobes 1 mm. or less, the tube cylindric, usually about 1.2 mm. long; faucal appendages borne at the base of the deep throat, invaginate, intrusive. In fields, prairies, waste places and rocky soils, from Wichita Co. s. to Webb Co. and w. to n.e. Panhandle and s.w. to Davis Mts., Mar.-June; from Kan. to Ida., s. to Tex., N.M., and n. Ariz.

9. HACKELIA OPIZ STICKSEED

Coarse biennial or perennial or rarely annual herbs; leaves alternate, broad and veiny; flowers in naked or inconspicuously bracted racemes paniculately disposed; pedicels slender, recurving in fruit; calyx cut to the base into spreading ovate to oblong or lanceolate lobes; corolla white or blue, with a short or elongate tube; lobes rounded, imbricate; throat with trapeziform intruded appendages; stamens included, affixed at middle of tube; filaments slender, short; anthers oblong to elliptic; style slender, scarcely if at all surpassing the mericarps; stigma capitate; ovules 4; mericarps 4, erect, ovoid, affixed ventrally to the pyramidal gynobase by a broad medial or submedial areola, margin with subulate glochidiate appendages that are frequently confluent at the base, back smooth or with glochidiate appendages.

A genus centering in western North America with outlying species in South America and Eurasia.

- 1. Mericarps subequally prickly over the whole back or face 1. *H. virginiana*.
- 1. Mericarps only marginally prickly, smooth, verrucose or with several small glochidiate prickles on back or face (2)
- 2(1). Flowers about 2.5 mm. long; nutlets about 2.5 mm. long, the prickles free to the base 2. *H. grisea*.
- 2. Flowers 4-6 mm. long; nutlets 3-4 mm. long, the prickles usually somewhat united at base (3)
- 3(2). Cauline leaves linear-oblong, sessile or nearly so; dorsal surface of mericarps smooth 3. *H. floribunda*.
- 3. Cauline leaves narrowly elliptic to lanceolate, noticeably petiolate; dorsal surface of mericarps with several minute glochidiate prickles .. 4. *H. pinetorum*.

1. *Hackelia virginiana* (L.) I. M. Johnst. Plant to about 1 m. tall, hirsute throughout, the stem freely branched above; radical leaves broadly ovate to cordate, narrowed to a slender petiole, to 2 dm. long; cauline leaves ovate-oblong to oblong-lanceolate, acuminate at apex, tapering to the sessile base, to 15 cm. long, progressively reduced above and passing into the bracts; the numerous loosely paniculate racemes divaricate, with small bracts; pedicels and flower each about 2 mm. long, frequently supra-axillary; corolla whitish, about 2 mm. wide; mericarps of the globose fruit equally short-glochidiate over the whole back, 3-4 mm. long. In rich woods and open thickets in n.e. Tex. and the Panhandle, July-Sept.; from Que. and Me., w. to S.D., s. to Ga., Ala., La. and Tex.

2. *Hackelia grisea* (Woot. & Standl.) I. M. Johnst. Plant biennial from a short thick taproot; stems stout, 8 dm. tall or less, simple below, canescent; basal leaves numerous, narrowly oblanceolate, obtuse, 3-5 cm. long; cauline leaves narrowly oblanceolate to linear-oblong, obtuse to acute, 2.5-4 cm. long, the upper sessile, the lower attenuate to a broad winged petiole; all leaves densely canescent on both surfaces, the hairs with large white bulbous bases; inflorescence sparse, with slender loosely few-flowered erect branches; bracts very small, lanceolate; pedicels 3-4 mm. long; sepals ovate, obtuse; corolla blue, 2.5 mm. long; mericarps 2.5 mm. long, the spines as long as the body, free to the base, the back papillose. In open woods of mt. canyons in the Trans-Pecos and N.M., July-Sept.

Its relatively small corollas, with ascending lobes, readily distinguish this species from other west American annual and biennial species in this genus.

3. *Hackelia floribunda* (Lehm.) I. M. Johnst. Plants erect, stout, from a short-lived perennial root, 5-12 dm. tall, the rough pubescence deflexed, mixed with some spreading hairs; leaves oblanceolate to linear or oblong, hirsutulous-appressed, the basal leaves petiolate, with spreading hairs, the stem leaves sessile above; racemes many, rather strict, densely flowered; pedicels 5-7 mm. long in fruit; corolla blue, 4-7 mm. broad; appendages small, obscurely papillate, not closing the throat; mericarps 3-5 mm. long, face of mericarp with a median ridge, muriculate, hirsutulous, without short glochidiate prickles, the marginal spines much-flattened at base, distinct or somewhat confluent, 4 to 6 on each side, mostly exceeding in width the face of the mericarp. Brushy slopes and edge of woods in the Trans-Pecos, July-Aug.; mostly w. U.S. and Can., e. to Ont. and Minn.

4. *Hackelia pinetorum* (Greene) I. M. Johnst. Stems erect-spreading, several from a woody rootstock, to 7 dm. high; cauline leaves petiolate, narrowly elliptic to lanceolate, obtuse-apiculate to subacute, to about 6 cm. long and 15 mm. wide; racemes simple or sparsely branched, erect or ascending, laxly many-flowered, elongate; flowers about 4 mm. long; mericarps 3-4 mm. long, the smooth disk with several minute glochidiate prickles. On sheltered ledges on summit of Mt. Livermore, Davis Mts., rare, Aug.-Oct.; also N.M.

10. CRYPTANTHA LEHM.

Annual or perennial¹ herbaceous or fruticlose plants, usually with coarse stiff pubescence; leaves opposite at base, firm, veinless; flowers white or very rarely yellow, in bractless or bracted spikes or racemes; calyx usually cut to the base, the lobes erect or connivent, linear or oblong; mature calyx investing the mericarps falling away individually; corolla with usually a short cylindrical tube, with or without scales at the base inside, the throat with intruded appendages; corolla lobes imbricate, rounded, spreading; style slender, short or long, included; stigma capitate; ovules 2 to 4; mericarps 1 to 4, erect, ovate to triangular, roughened or smooth, margined or marginless, affixed laterally through a medial ventral and commonly basally forked groove to a usually columnar subulate or pyramidal gynobase.

One of the largest and most perplexing genera in the family, consisting of 100 or more species. It is exclusively American, mostly in western United States. Several of the species are reported to have value as forage for sheep.

1. Plants annual; stems slender (Doubtful cases should be keyed under both alternatives) (2)
1. Plants perennial; stems usually rather stout (12)

- 2(1). Cymes with numerous evident bracts (3)
- 2. Cymes bractless or having only a few very inconspicuous bracts (6)
- 3(2). Gynobase elongate, slender, surpassing the mericarps; mericarps smooth, grooved on the venter; plants small, with very slender wiry stems and small leaves (less than 1 cm. long and 1 mm. broad); roots and base of plants usually charged with a purple dye1. *C. micrantha*.
- 3. Gynobase evidently much shorter than the mericarps; some or all the mericarps with a warty surface and their venter largely occupied by a triangular excavated attachment scar; plants moderate-sized, the stems 1-7 mm. thick and not wiry; leaves 2-6 mm. broad (4)
- 4(3). Mericarps strongly heteromorphic, the adaxial one differing from the other three in being much larger and more firmly affixed, only the three smaller mericarps coarsely warted and their venter occupied by a large triangular excavated attachment scar; calyx lobes at maturity with conspicuously thickened and indurated midribs2. *C. minima*.
- 4. Mericarps all alike, all coarsely warted and all having the venter occupied by a large triangular excavated attachment scar; calyx lobes at maturity with only moderately thickened midribs (5)
- 5(4). Plant spring-flowering; stems dichotomously branched from the base outward; plant usually low (5-15 cm. high) and spreading, commonly greener and more coarsely hispid than in *C. albida* and the calyx larger and having a broader base3. *C. mexicana*.
- 5. Plant summer-flowering; main stems straight and erect, forming a central axis producing dichotomously branching laterals; plant usually taller (15-40 cm. high) and having more slender branches than *C. mexicana*4. *C. albida*.
- 6(2). Mericarps with a conspicuous marginal wing5. *C. pterocarya* var. *cycloptera*.
- 6. Mericarps not winged (7)
- 7(6). Back of mericarp distinctly rimmed by a narrow slightly thickened pallid margin; mericarps glossy, vitreous, bent6. *C. pusilla*.
- 7. Back of mericarp unrimmed; mericarps dull, not bent (8)
- 8(7). Fruit consisting of 4 or fewer mericarps; adaxial (not abaxial) mericarp always present, densely covered with abundant, very crowded and very minute warts; when 2 or more mericarps are matured the adaxial one differs from the others in being noticeably larger and more firmly affixed and in having a different shape and very different surface markings (9)
- 8. Fruit consisting of 4 mericarps; abaxial (not adaxial) mericarp usually the largest and most firmly attached but not differentiated from the other mericarps within the fruit in either shape or surface markings; mericarps all coarsely but not very abundantly warted (11)
- 9(8). Mericarp one, only rarely more; adaxial mericarp bearing only crowded, abundant, very minute warts; fruiting pedicels 0.2-0.5 mm. long8. *C. texana*.
- 9. Mericarps usually 4; adaxial mericarp with slightly taller papillae or spicules mixed among the more abundant, crowded, very minute warts covering its surface; fruiting pedicels 1-2 mm. long (10)
- 10(9). Corolla 4.5 mm. in maximum length, limb 3-6 mm. broad, lobes rounded, 1.5-2 mm. broad, tube 1.7-2 mm. long and 1 mm. thick; anthers 0.5 mm. long, borne about 1.2 mm. above base of corolla tube7. *C. crassisejala* var. *crassisejala*.
- 10. Corolla 2-3 mm. in maximum length, limb 2.5 mm. broad, lobes rounded, 0.6-0.8 mm. broad, tube 1.5-2 mm. long; anthers 0.4 mm. long, borne 1 mm. above base of corolla tube7. *C. crassisejala* var. *elachantha*.

- 11(8). Calyx in fruit 2-4 mm. long, the lobes not villose; mericarps heteromorphic, triangular-ovate, usually dark-colored, 0.7-1.2 mm. long 9. *C. angustifolia*.
11. Calyx in fruit 7-10 mm. long, the lobes conspicuously white-villose along the margin below the middle; mericarps all alike, lanceolate, 1.5-2 mm. long, prominently warted 10. *C. barbiger*a.
- 12(1). Mericarps smooth, not spaced equally about the gynobase, on the axial and abaxial side of gynobase the mericarps closely juxtaposed, laterally they are usually evidently separated, hence borne in opposing pairs; stamens always borne at the top of the corolla tube and directly beneath the faucal appendages (13)
12. Mericarps rough, equally spaced about the gynobase; corolla tube elongate, lacking an annulus, surpassing the calyx lobes for 1-3 mm. (15)
- 13(12). Corolla lacking an annulus; faucal appendages trapeziform, about as broad as long, about 0.5 mm. long; mature calyx 5-10 mm. long 12. *C. Coryi*.
13. Corolla bearing an evident very well-developed flangelike annulus inside the corolla tube just above its base; faucal appendages elongate, lingulate, about 1 mm. long; mature calyx about 5 mm. long (14)
- 14(13). Plant at maturity usually leafless at the base; stems frequently branching, commonly arising from a loose caudex; indument usually smooth, consisting of slender appressed hairs 11. *C. Jamesii* var. *Jamesii*.
14. Plant at maturity with usually simple stems and some persistent basal leaves; stems arising directly from a taproot or forming a small very compact caudex; indument hispid with evident stiff spreading hairs 1-3 mm. long 11. *C. Jamesii* var. *setosa*.
- 15(12). Flowers monomorphic; stamens always borne slightly above the middle of the corolla tube; style never projecting above the stamens; faucal appendages scantily puberulent or nearly glabrous; mericarps coarsely tuberculate; inflorescence soon lax and thyrsoid; frequent in western Trans-Pecos Texas 13. *C. oblata*.
15. Flowers strongly dimorphic, distinctly heterostyled; style elongate and nearly exerted from the corolla tube when the stamens are borne in mid-tube, and reaching up only to slightly above mid-tube when the stamens are borne slightly exerted at the summit of the tube; faucal appendages puberulent; inflorescence usually capitate except sometimes in extreme maturity; plants local (16)
- 16(15). Mericarps minutely but distinctly tuberculate or rugose; heads of flowers commonly 2-3 cm. in diameter; Guadalupe and Apache mts. 14. *C. Paysonii*.
16. Mericarps obscurely roughened, nearly smooth; heads of flowers 1-2.5 cm. broad; stems slender; Big Bend area 15. *C. crassipes*.

1. *Cryptantha micrantha* (Torr.) I. M. Johnst. Small annual, 3-10 cm. tall; stems minutely strigose, erect or ascending, loosely and dichotomously branched; leaves usually numerous, linear- to oblong-ob lanceolate, rounded or obtuse at the apex, to 8 mm. long and 1 mm. broad, strigose or the hairs loosely appressed, the uppermost leaves transformed into bracts of the inflorescence; inflorescence consisting of densely flowered, clustered, short, abundantly bracted scorpioid biseriata cymes terminating the stems and branches; calyx at anthesis 0.8-1 mm. long, at maturity to 1.5 mm. long, very tardily deciduous, the lobes linear or lance-linear, hispidulous, separated by an open sinus about as wide as the lobes; corolla minute, inconspicuous, white, 1.3-1.8 mm. in total length, shortly exerted from the calyx, the throat slightly constricted and bearing 5 minute yellow plaits as faucal appendages; mericarps 4, all alike or sometimes the abaxial one slightly the largest and the most firmly affixed, to 1 mm. long and 0.5 mm. broad, lanceolate, dark-colored, smooth, the back convex, the venter grooved from base to apex. *Eritrichium micranthum* Torr., *Krynitzkia micrantha* (Torr.) Gray, *Eremocarya micrantha* (Torr.) Gray. Rare and local in w. Tex., where it is apparently restricted to sandy places, Mar.-June; from w. Tex. and N.M. to Ariz. and Calif., n. through Nev. into e. Ore.

Plants of this species are readily recognizable because of their small size, wiry stems, diminutive leaves, elongate gynobase, short dense completely bracted cymes, and presence of a dye in root and base of stems.

2. *Cryptantha minima* Rydb. Plant annual, usually about 1 dm. tall and 2 dm. broad but occasionally much larger; stems few to numerous, usually ascending or decumbent, with ascending branches, with minute slender appressed hairs and spreading stiff usually pungent bristles; leaves narrowly oblanceolate to linear-oblanceolate, obtuse to acute at apex, to 4 cm. long and 6 mm. broad, gradually reduced up the stem and continuing into the inflorescence as foliaceous bracts, with appressed or ascending slender minute hairs and also stiff pungent bristles which frequently arise from mineralized disks; inflorescence consisting of single or paired, evidently bracted scorpioid cymes; calyx at anthesis 2-2.5 mm. long, subsessile; mature calyx deciduous, commonly about 5 mm. long, asymmetric, gibbous on adaxial side, spreading or somewhat decurved in age; corolla white, 2.5-3 mm. in maximum length, the rounded lobes ascending and scarcely surpassing the calyx; corolla throat partially closed by trapeziform puberulent invaginate faucal appendages, these with a short medial downward prolongation in the upper part of the tube; adaxial mericarp 1.6-2 mm. long, about 1.2 mm. broad; the 3 consimilar mericarps ovate, 1.2-1.5 mm. long, 0.7-0.9 mm. broad, and 0.5-0.6 mm. thick. *Eritrichium hispidum* Buckl. Frequenting sandy or gravelly places in the portions of the Tex. Panhandle below the High Plains (i.e., along canyons cut into the High Plains and along and e. of the breaks at their e. border), thence extending s. into e. portions of Trans-Pecos, with outlying stations in Archer and Val Verde cos., Mar.-June; from s. Can. through Mont. and the Dakotas, s. to Tex. and N.M.

A species very closely related to *C. crassisepala*, which differs in having naked rather than abundantly bracted cymes, and in having the surface of the large adaxial mericarp minutely warted with intermixed protruding elongate papillae or spicules rather than minutely warted only.

3. *Cryptantha mexicana* (Brandeg.) I. M. Johnst. A low loosely spreading or less commonly erect spring-flowering very fertile annual, 5-20 cm. tall, usually broader than tall; stems several to many, usually loosely decumbent or laxly ascending, hispid and sometimes also sparingly strigose, repeatedly dichotomous from the base outward; leaves mostly flat, oblong-oblanceolate to narrowly oblong, hispid with spreading hairs arising from discoid mineralized bases, to 45 mm. long and 6 mm. wide, gradually smaller up the stem and into the thyse, floriferous to below the middle and frequently even down to the base of the stems; the cymes numerous, to 15 cm. long, densely to loosely flowered; calyx at anthesis to 2.5 mm. long, the lobes lanceolate; calyx at maturity to 4 mm. long and 2.5 mm. broad above the base, broadly ovoid, eventually deciduous; corolla inconspicuous, white, 2-2.5 mm. long, the lobes rounded and ascending; faucal appendages well-developed, puberulent, invaginate, trapeziform, almost 2 mm. high; mericarps triangular-ovate, to 1.3 mm. long and 0.9 mm. broad, homomorphous (but the abaxial mericarp sometimes more firmly affixed than the other 3 mericarps). Usually in calcareous soils associated with limestone or caliche from the Trans-Pecos to Howard, Tom Green, Edwards, McMullen and Cameron cos., Apr.-June; from Tex. s. into n. N.L. and s. Coah.

In western Texas the plant is frequently abundant along the shoulders of modern highways and possibly may be aided in dissemination and be increasing its geographic range through assistance of the automobile. In the past this plant has been confused with the closely related *C. albida* and not distinguished from it.

4. *Cryptantha albida* (H.B.K.) I. M. Johnst. An erect, paniculately branching summer-flowering annual, 15-40 cm. tall; stems single or more commonly several, erect or short-decumbent only at the very base, rather stiff and strong, each stem developing a clearly defined straight erect central axis which produces (at least above the middle) numerous well-developed loosely ascending dichotomously branching laterals, cinereous, antrorsely strigose and sparingly hispid; leaves spatulate to spatulate-linear, abundant along the stems before anthesis, to 3 cm. long and towards the apex 5 mm. broad, usually conduplicate, the lower surface strigose or with only a few spreading hairs mostly with mineralized discoid bases, the upper surface scantily hairy or almost glabrous; inflorescences terminal on the main stem and on the many leafy branches and branchlets, dichotomous, composed of solitary or rarely geminate slender cymes; calyx at anthesis about 2 mm. long, the lobes lanceolate; calyx at maturity to 3 mm. long and 2 mm.

broad, ovoid, eventually deciduous, the lobes connivent, unequal, pungent-hispid; corolla white, inconspicuous, 2.5-3 mm. long, the lobes broadly obovate, rounded and ascending, about 1 mm. long; faucal appendages well-developed, invaginate, trapeziform, emarginate, puberulent, about 0.2 mm. high and slightly broader at the base; mericarps triangular-ovate, to 1.3 mm. long and 0.9 mm. broad, homomorphous (the axial one differentiated only in being more firmly affixed than the other three). Mostly in soils derived from volcanic rock but rarely in limestones in the w. Trans-Pecos, mostly July-Aug.; in w. Tex. and s.e. Ariz., s. to cen. Mex. Indistinguishable plants also occur in n.w. Arg.

5. *Cryptantha pterocarya* (Torr.) Greene var. *cycloptera* (Greene) Macbr. Annual, erect, simple or ascendingly branched, 1-4 dm. tall; stems strigose or short hispid with appressed or spreading hairs; leaves broadly linear or the reduced upper ones oblong to oblanceolate, obtuse, the lowermost leaves commonly to 4 cm. long and 4 mm. broad, strigose or short hispid with the hairs commonly arising from bulbous or discoid bases; inflorescence terminal on the leafy stems and branches, pedunculate, consisting of geminate or ternate scorpioid bractless cymes to 8 cm. long; flowers unilateral and biserial, usually becoming loose at maturity; calyx at anthesis about 2 mm. long; calyx at maturity becoming greatly enlarged, to 5 mm. long and 4 mm. broad, persisting until after the fall of the mericarps, symmetric, the lobes united above the base, loosely connivent, broad, elliptic to lance-ovate, hispidulous on the moderately prominent midrib; corolla inconspicuous, white, total length 2-3 mm. long, the lobes suborbicular and to 0.8 mm. in diameter, the throat bearing 5 weakly intruded convex faucal appendages; mericarps 4, all alike, consisting of a lanceolate body laterally surrounded by a spreading wing margin 0.3-0.5 mm. broad, viewed dorsally the winged mericarps 2-2.5 mm. long and 1.7-2 mm. broad, edge of the wing entire or crenate or more or less dentate-lobulate, body of mericarp with the back convex and conspicuously warted. Usually in limestone areas on hills and base of cliffs in the Trans-Pecos, along the valley of the Rio Grande and bordering mts., from s. Presidio Co. to Sierra Blanca and the vicinity of El Paso, Mar.-May; also in w. N.M., Ariz. and n. into Ut. and Nev.

6. *Cryptantha pusilla* (T. & G.) Greene. An early spring herb, with slender root, usually low and spreading; stems commonly numerous, laxly decumbent or prostrate, to 3 dm. long and 1.5 mm. thick, grayish, slender, strictly branched, strigose and hispidulous; leaves oblanceolate to linear, to 3 cm. long and 3 mm. broad, hispidulous, the hairs usually arising from thickened mineralized bases; inflorescence consisting of many solitary or less frequently geminate scorpioid cymes borne terminal on the stems and many branches; cymes slender, naked or with a few scattered small inconspicuous bracts, unilateral, 2-8 (-15) cm. long; calyx at anthesis about 1 mm. long, hispidulous, noticeably tawny; calyx at maturity to 2.5 mm. long and 2 mm. broad, early deciduous, the lobes lanceolate, noticeably unequal; corolla minute, usually 1.5 mm. long, only the ascending obovate lobes surpassing the calyx; faucal appendages weak and inconspicuous, hemispheric; fruit usually 1.1 mm. in diameter and 0.9 mm. tall; mericarps 4, dark-colored, porcelainlike, lustrous, triangular-ovate, somewhat bent and incurving, 0.7-1.0 mm. long, 0.6-0.8 mm. broad, back convex, bearing pale warts, margin pallid and somewhat thickened. *Eritrichium pusillum* T. & G., *Krynitzkia pusilla* (T. & G.) Gray. On open rocky hills, flats and in canyons in the Trans-Pecos, Feb.-May; Tex., N.M., Ariz., s. to Son., Dgo. and Chih.

7. *Cryptantha crassisepala* (T. & G.) Greene var. *crassisepala*. Annual, 10-15 (-25) cm. tall; stems few to numerous, usually decumbent or sprawling, loosely branched, usually bearing short slender appressed or spreading hairs and stiff spreading pungent bristles; leaves narrowly oblanceolate, rounded or obtuse at the apex, bearing appressed or ascending slender minute hairs and also stiff pungent bristles, the latter frequently with discoid bases, the lower leaves to 5 cm. long and 5 mm. broad, the upper leaves gradually reduced; inflorescence consisting of bractless scorpioid cymes borne solitary or geminate; cymes strongly unilateral, to 15 cm. long, bearing the flowers in 2 strongly diverging ranks; calyx at anthesis 2-2.5 mm. long; calyx at maturity deciduous, to 8 mm. long, asymmetric, gibbous on the adaxial side, the lobes developing extremely prominent excessively thickened indurate midribs armed with long spreading very pungent bristles; corolla white; faucal appendages invaginate, puberulent, trapeziform with a medial downward glandular prolongation in the upper part of the tube; mericarps strongly

heteromorphic with the adaxial one much the largest (to 2.5 mm. long and 1.2 mm. broad) and most firmly affixed. *Eritrichium crassisepalum* T. & G., *Krynitzkia crassisepala* (T. & G.) Gray. Dunes and other sandy places; most abundant n. of the Pecos River in Loving, Ward, Upton, Winkler and Ector cos., with outlying stations in Kent and Mitchell cos. and in s. Pecos and n. Brewster cos., Mar.-May; also e. of the Pecos River in Eddy Co., N.M.

Var. *elachantha* I. M. Johnst. Characters in the key. Usually in gravelly places in the Trans-Pecos, from Reeves and Brewster cos., w. through N.M. into Ariz., s. Ut. and adj. Mex.

8. *Cryptantha texana* (A.DC.) Greene. Annual, at first erect but usually spreading in age; stems usually several or more, decumbent, to 4 dm. long, loosely and ascendingly branched, clothed with slender rigid usually spreading hairs; leaves thickish, conduplicate, oblanceolate, retuse or obtuse to rounded at apex, covered with erect or ascending, stiff, slender hairs springing from mineralized discoid bases, the lower leaves to 6 cm. long and 9 mm. wide, the middle and upper leaves gradually reduced; inflorescence consisting of solitary or geminate bractless scorpioid cymes; cymes strongly unilateral, bearing the flowers in 2 strongly diverging ranks, in age loosely flowered and to 15 cm. long; calyx at anthesis to 2.5 mm. long; calyx at maturity deciduous, to 5.5 mm. long, asymmetric and spreading or even somewhat decurved; calyx lobes connivent, linear, the midrib moderately prominent, thickened and somewhat indurate, armed with stout spreading pungent hairs; corolla white, 2.8 mm. in maximum length, the lobes ascending, rounded; faucal appendages high-convex, with a short medial downward glandular prolongation inside the corolla tube. *Eritrichium texanum* A.DC., *Myosotis texana* (A.DC.) Hook., *Krynitzkia texana* (A.DC.) Gray. In sandy places, chiefly s. of the valley of the Colorado River, from Mason, Llano, Travis and Bastrop cos. s. to Jim Hogg, Brooks and Willacy cos., also with an outlying n. station along the Brazos near Glen Rose, Somervell Co., Mar.-June; endemic.

This is the most easterly ranging of the species of *Cryptantha*.

9. *Cryptantha angustifolia* (Torr.) Greene. Annual, usually spreading, to 15 cm. tall; stems usually several to numerous, to 3 dm. long, decumbent or ascending, dichotomously branched, grayish from an abundance of pale very slender spreading hairs, in drying frequently becoming reddish or reddish-brown; leaves numerous, narrowly oblanceolate or nearly linear, 1-3 (-4) cm. long, 1-2 (-3) mm. wide, hispidulous, the hairs straight and spreading, springing from thickened mineralized bases; inflorescence consisting of usually very abundant, slender, commonly geminate scorpioid cymes that remain closely flowered even in fruit; calyx at anthesis about 1.5 mm. long, the lobes armed with slender spreading pungent hairs; corolla white, inconspicuous, total length about 2 mm., scarcely exerted, the lobes suborbicular and ascending; faucal appendages weakly intruded, hemispheric. In very arid areas in the Trans-Pecos, in the warmer parts of the Big Bend and along the valley of the Rio Grande n.w. to El Paso, Feb.-May; from Tex. through N.M. to the deserts of Ariz. and Calif.; also adj. Mex.

10. *Cryptantha barbiger*a (Gray) Greene. Annual to 4 dm. tall; stems one or more, bristly with slender spreading hairs 1-2 mm. long, erect or sometimes sprawling, branches few to numerous, frequently well-developed, strictly ascending; leaves obtuse, linear or oblong to narrowly lanceolate or oblanceolate, to 8 cm. long and 9 mm. wide, hispid; inflorescence consisting of pedunculate geminate or less commonly ternate scorpioid cymes borne terminal on the stems and major branches; cymes usually not exceeding 1 dm. in length but at times greatly elongated in fruit and as much as 30 cm. long; calyx at anthesis about 4 mm. long, the lobes usually surpassing the corolla, bristly and below the middle villose; calyx at maturity as much as 1 cm. long, subsessile, promptly deciduous when fruit is ripe, midrib of the linear-lanceolate lobes armed with slender pale spreading bristles 1-3.5 mm. long; corolla inconspicuous, white, 2-3 mm. long, the lobes suborbicular and ascending; faucal appendages weakly intruded, hemispheric, puberulent. In Tex. only in the Franklin Mts. on talus in an igneous area on the w. slope and on limestone on the e. slope, Apr.-May; from w. Tex., Ariz. and s. Ut., w. into the deserts of Calif. and n. Mex.

11. *Cryptantha Jamesii* (Torr.) Pays. var. *Jamesii*. Perennial but probably persisting for no more than 2 or 3 seasons; stems usually several, loosely clustered, from the summit of a slender woody taproot or a decumbent caudex, leafy, erect or ascending, usually

with strict branches, stiffish, 2-3 dm. or rarely to 5 dm. tall, strigose, pale, developing from short leafy suckers that appear on the caudex or on the base of the fertile stems usually late in the previous season; leaves oblanceolate, somewhat coriaceous, usually flat, pale-green, rather smooth, thinly strigose with slender closely appressed minute hairs and (particularly on the lower surface) intermixed with slightly coarser, stiffer, also closely appressed bristles that arise from very inconspicuous discoid bases, to 8 cm. long and 1 cm. wide; inflorescence terminal, forming a thyrses occupying upper quarter of the stem or less, usually composed of about six major scorpioid cymes; cymes densely flowered and even crowded in fruit; bracts not conspicuous, spreading, 3-8 mm. long; calyx at anthesis 2-3 mm. long, the lobes lanceolate, equaling or evidently longer than the corolla tube, strigose, bristles inconspicuous and appressed; corolla white, the limb spreading and 5-8 mm. in diameter, the tube usually shorter than the calyx; faucal appendages yellow, well-developed; mericarps in age more or less brownish and mottled, lustrous. *Eritrichium Jamesii* Torr., *Krynitzkia Jamesii* (Torr.) Gray. Frequent on dunes and in sandy places on the high plains of the Tex. Panhandle and s. to the dunes of Ward and Crane cos., Apr.-July; a characteristic plant of the Great Plains, ranging from Tex. n. to s.e. Wyo. and w. S.D.

Var. *setosa* (M. E. Jones) Shinn. Plant hispid, its indument consisting of abundant minute appressed hairs and intermixed stiff spreading hairs 1-3 mm. long; leaves not smooth and tidy in appearance, rough hairy; the lower surface usually with evident discoid mineralized hair bases; blade usually more or less conduplicate; stems usually simple, densely tufted from the crown of the taproot or in age arising from a small (3-6 cm. broad), very dense flat caudex. *C. Jamesii* var. *laxa* (Macbr.) Pays. and var. *multicaulis* (Torr.) Pays. Confined to gravelly volcanic soils in the Davis Mts. in the Trans-Pecos, Mar.-June; Tex., N.M., Ariz. and Chih.

12. *Cryptantha Coryi* I. M. Johnst. Perennial, usually with several stems arising from the clusters of leaves crowning the woody taproot, usually about 3 (1.5-5) dm. tall, not forming a caudex; stems erect or ascending, branched only in the inflorescence, clothed with an abundance of very slender fine retrorsely appressed hairs and also bristly with spreading pungent hairs; leaves pale-tomentulose with a coating of fine appressed hairs, usually also bearing some loosely appressed bristles, those in the basal clusters oblanceolate, to 15 cm. long and 1 cm. broad, acute to obtuse at apex, the smaller cauline leaves spatulate-oblong to oblong; inflorescence at first capitate but soon developing a very loose and open thyrses composed of 3 or 4 major scorpioid cymes (becoming 6-15 cm. long) and several few-flowered small glomerules in the uppermost leaf axils; bracts lanceolate, only the lower ones longer than the calyx; calyx at anthesis 4-6 mm. long, the lobes lanceolate, tomentulose and bristly; corolla white, yellow in the throat, commonly becoming somewhat pinkish in drying, the limb 7-10 mm. broad, the tube slightly shorter than the calyx lobes; faucal appendages yellow, trapeziform, emarginate, densely puberulent, base decurrent and prolonged downward as puberulent lines on the inner surface of the corolla tube to between the tips of the anthers; mericarps angulate, usually 4, gray and frequently somewhat mottled with brown, lustrous or dull. *Hemisphaerocarya texana* Brand. On talus and rocky benches, in and about limestone hills, usually if not exclusively in Cretaceous areas, from Maverick, Tom Green, Howard and Lubbock cos. w. to Brewster and s. Culberson cos., Mar.-June; also N.M.

This species is referred to the Mexican *C. Palmeri* (Gray) Pays. by some authors.

13. *Cryptantha oblata* (M. E. Jones) Pays. Usually a short-lived perennial, 2-4 dm. tall; stems erect or ascending, several to many arising from leaf clusters crowning a taproot, branched only in the inflorescence, strigulose with slender retrorsely appressed hairs and also decidedly bristly with stiff spreading hairs 1-3 mm. long; leaves of the basal cluster usually persisting, elongate-oblanceolate, to 15 cm. long and 1 cm. broad, bearing abundant fine appressed hairs to form a smooth strigulose-tomentulose indument from which emerge coarse scattered bristles; cauline leaves gradually reduced up the stem and greener and more bristly than the basal leaves; inflorescence at first capitate but eventually developing into a very loose, open, very hispid thyrses composed of usually 5 to 7 (or rarely even 9) densely flowered cymes 4-10 cm. long and several few-flowered glomerules in the uppermost leaf axils; bracts of the cyme very slender and elongate; calyx at anthesis 6-7 mm. long, hispid; calyx at maturity ovate to lanceolate in outline, 7-12 mm. long, the lobes decidedly unequal, surpassing the mature fruits; corolla white, salverform, 12-18 mm. long. *Krynitzkia oblata* (M. E. Jones) Pays., *Oreocarya oblata*

(M. E. Jones) Macbr., *Hemisphaerocarya oblata* (M. E. Jones) Brand. Usually on alluvial soils or talus, on silty valley flats or on gravelly benches at the base of mts., from El Paso Co. and adj. N.M. e. to w. Loving Co., n.w. Brewster Co. and cen. Presidio Co., Mar.-June; endemic.

14. *Cryptantha Paysonii* (Macbr.) I. M. Johnst. Perennial, 10-20 (-25) cm. tall, with several stems that are finely hairy and bristly; leaves mostly basal, in numerous crowded clusters borne on the crown of the taproot or on the short ascending or more or less spreading branches of a crowded caudex, cinereous or somewhat canescent, moderately to densely clothed with abundant minute mostly appressed slender hairs and with less abundant bristles arising from mineralized bases, the basal leaves oblanceolate, to 9 cm. long and 15 mm. broad; inflorescence at first capitate and terminal then usually developing one to several minor heads in the uppermost leaf axils; calyx at anthesis 5-8 mm. long, villose-hispid; calyx at maturity lanceolate in outline, 8-12 mm. long, the lobes connivent, unequal, narrowly lanceolate, surpassing the mature mericarp; corolla white with a yellow throat, frequently becoming yellowish or pinkish in drying, salverform, the limb 8-10 mm. broad, the tube surpassing the calyx lobes; faucal appendages prominent, trapeziform, puberulent. In Culberson Co., about the Guadalupe and Apache mts., Apr.-June; also N.M. The known collections are all from localities with Paleozoic rock.

15. *Cryptantha crassipes* I. M. Johnst. Strong perennial, cinereous or somewhat silvery, developing a dense, high-domed caudex formed of very numerous strict crowded caudex branches and intermixed clay, this bearing many crowded fascicles of basal leaves and numerous simple slender erect leafy flower-bearing stems to 25 cm. tall, bearing minute appressed (mostly retrorse) hairs and less numerous spreading bristles; leaves smooth with a dense indument of minute hairs and intermixed bristles or bearing spreading hairs and bristles only on the margin, the basal leaves oblanceolate, to 6 cm. long and 7 mm. broad, the apex acutish, the cauline leaves several and gradually smaller up the stem; inflorescence at anthesis usually a terminal capitate cluster, occasionally accompanied by one or more inconspicuous few-flowered glomerules borne in the uppermost leaf axils; calyx at anthesis 6-7 mm. long; calyx in fruit 8-11 mm. long, densely and minutely appressed hairy and with intermixed slender spreading bristles, the lobes lanceolate; corolla white with a yellow throat, salverform, the limb spreading and 8-10 mm. in diameter, the tube surpassing the calyx; faucal appendages prominent, densely puberulent. Known only from barren clay flats w. of Terlingua Creek along the road to Agua Fria Mts., n. of Agua Fria Spring, Brewster Co., Apr.-May; endemic.

11. AMSINCKIA LEHM. FIDDLE-NECK. TARWEED

Annual bristly herbs; leaves alternate, linear to ovate, usually veinless; racemes usually bractless; calyx cut to base into erect lanceolate or oblong lobes; corolla tubular or salverform, heterostyled, yellow or orange; tube cylindrical, glabrous, unappendaged; lobes spreading, rounded, imbricate; throat unappendaged; stamens included, affixed in the tube; filaments very short; anthers oblong, obtuse; style filiform, included; stigma capitate, emarginate; ovules 4, cotyledons 2-parted; mericarps 4, erect, angulate-ovoid, smooth or rough, unmarginated, strongly keeled ventrally; areola inframedial, small, carunculate; gynobase pyramidal, frustrate, about half the height of the mericarps.

About 50 species of considerable technical difficulty which centers in western North America.

- 1. Corolla salverform, the throat constricted and closed or nearly so by intruding hairy saccate processes; stamens inserted evenly in one plane on the tube well below the constriction1. *A. lycopsoides*.
- 1. Corolla narrowly funnellform, with the throat open and glabrous; stamens inserted (usually more or less irregularly) in the corolla throat (2)
- 2(1). Corolla pale-yellow, 4-5 mm. long, little or not at all exserted beyond the calyx lobe2. *A. micrantha*.
- 2. Corolla orange-yellow, 8-10 mm. long, well exserted beyond the calyx; plants usually green; stems hirsute-bristly but with little or no fine-appressed hairs3. *A. intermedia*.

1. *Amsinckia lycopsoides* Lehm. Plant erect to procumbent, with long spreading branches, rather stout, bristly-hirsute with scant or no fine pubescence at least below, 3-10 dm. tall; leaves bristly-hirsute, the hairs spreading or appressed, the lower linear or linear-oblong, 6-15 cm. long, the upper lanceolate or the uppermost narrowly ovate; spikes usually not greatly elongating in fruit, bracteate below; fruiting calyx 6-10 mm. long, the lobes narrowly linear-lanceolate, sparsely bristly on the back, the margins densely ciliate with long slender hairs; corolla deep-yellow, 7-10 mm. long, the tube well-exserted, the throat nearly closed by hairy saccate intrusions; mericarps triangular-ovate, 2.5-3 mm. long, not strongly keeled dorsally, closely muricate, not rugose, the points usually not in definite rows. Usually in moist open ground; w. U.S., reported from Tex. but no specimen seen, spring.

2. *Amsinckia micrantha* Suksd. Plant slender, the stem simple or freely branched from the base and usually decumbent, 3-6 dm. tall, bristly-hirsute with little or no fine pubescence; leaves broadly linear or oblong, the upper sometimes lanceolate, 4-10 cm. long, thin, bristly, the hairs mostly spreading and strongly pustulate; spikes becoming lax and greatly elongated, with few bracts or none; fruiting calyx 6-8 mm. long, the lobes narrowly to broadly lanceolate, thin, bristly, the lower bristles somewhat reflexed; corolla light-yellow, 4-5 mm. long, the tube slightly or not at all surpassing the calyx, the lobes minute; stamens usually inserted just below opening of corolla; mericarps triangular, 2.5-3 mm. long, the dorsal keel with a narrow strongly toothed ridge, with similar ridges on either side, the area between the ridges finely and evenly verrucose. Dry ground or grasslands, isolated in cen. Tex., Mar.-May; n.w. U.S. and B.C.

3. *Amsinckia intermedia* Fisch. & Mey. RANCHERS FIREWEED. Stems varying from simple and strictly erect to widely branched, 2-10 dm. high, sparsely bristly, tomentose near base of spikes; basal and lower cauline leaves linear to linear-lanceolate, acute at apex, clasping at base, thinly hirsute with spreading pustulate hairs; spikes abbreviated, leafy-bracted at base, becoming somewhat elongate in fruit; calyx lobes linear, about half as long as corolla, dorsally rufous-hispid, densely white-hirsute on margins; corolla orange-yellow, 8-10 mm. long, 3-6 mm. broad; mericarps 2.5-3 mm. long, grayish, incurved, narrowly keeled and rugose on back, the surface papillate or tuberculate. Grasslands on plateaus in the Trans-Pecos, Feb.-Apr.; from w. Tex. and Ariz., n. to Ida. and westw.

12. MYOSOTIS L.

SCORPION-GRASS. FORGET-ME-NOT

Annual or perennial herbs; leaves alternate; racemes bractless or bracted; calyx cut to beyond the middle into lanceolate or triangular lobes; corolla blue, white or rarely rose, with short tube, the lobes contorted, rounded, spreading, the throat with intruded appendages; stamens affixed on tube, included or exserted, the filaments filiform; anthers oblong or ovate, obtuse; ovules 4; mericarps 4, erect, ovoid to ellipsoid, smooth and shiny, with a basal areola; gynobase flat or high convex; style filiform; stigma disciform.

About 50 species centered in the Old World. It is separated from practically all other genera of the subfamily Boraginoideae by the contorted rather than imbricate aestivation of the corolla.

1. Fruiting calyx more than 5 mm. in length; flowers rather distant on rachis, mostly more than 1 cm. apart 1. *M. macrosperma*.

1. Fruiting calyx less than 5 mm. in length; flowers close on rachis, less than 1 cm. apart 2. *M. verna*.

1. *Myosotis macrosperma* Engelm. Erect annual, 2-5 dm. tall, hispidulous with spreading hairs, above the middle tending to be strigose; stems usually simple only when young, commonly with elongate leafy fertile branches at least above the middle and sometimes also from the lower leaf axils and even from the base of the main stem; leaves veinless, the basal ones forming a short-lived vernal rosette, the cauline leaves rather numerous, the upper ones only moderately reduced in size, hispidulous, the stiffish hairs arising from inconspicuous bulbous or discoid mineralized bases, the larger leaves to 75 mm. long and 16 mm. wide; cymes racemose, usually with a few leafy bracts at the base, not forking, at maturity stiffish, erect, straight, to 35 cm. long, eventually becoming loosely flowered

and in age becoming naked as the older fruiting calyces detach from the summit of the pedicel and fall away; calyx at anthesis 2.5-3 mm. long, unequally lobed, bearing abundant appressed uncinata hairs, the mature calyx covered with hooked hairs and enclosing the ripe mericarps functioning as a small bur suitable for animal dispersal; pedicel at maturity 2-6 mm. long; corolla white or at times slightly bluish, 2.5-3 mm. long, exerted with at least the lobes surpassing even the longer calyx lobes. *M. verna* var. *macrosperma* (Engelm.) Chapm., *M. virginica* var. *macrosperma* (Engelm.) Fern. Usually in rich soil of woods and bottomlands in n.e. and e. Tex., s.e. to the coast, Mar.-May; from Md. to Fla., w. to Ill., Mo. and Tex.

2. *Myosotis verna* Nutt. Erect annual, 5-35 cm. tall; stems simple or commonly branched only above in the inflorescence, occasionally with leafy fertile branches from most of the leaf axils along the stem, hispidulous or hispid-villose; leaves veinless, numerous, the basal ones forming a short-lived vernal rosette, the upper cauline leaves only moderately reduced in size, hispidulous, the stiffish hairs arising from inconspicuous bulbous or discoid bases, especially on the under surface, the larger leaves to 4 cm. long and 1 cm. wide; cymes racemose, terminal, not forked, at maturity stiffish, erect, straight, to 15 cm. long, eventually becoming loosely flowered; calyx at anthesis about 2.5 mm. long, unequally 5-lobed, densely hispidulous and usually with only a few of the hairs uncinata; corolla white, 2.5-3 mm. long, exerted, with the lobes surpassing even the longest calyx lobe. In rocky woods, on slopes and banks, in prairies and open woodlands in n.e. Tex., Dallas to Travis and Harris cos., eastw. and northw., Mar.-May; from N.E. to Fla., w. to B.C., Calif., Ida., and Tex.

13. ANTIPHYTUM DC.

Perennial fruticose or fruticulose plants; leaves opposite at least at the very base of the plant, linear to lanceolate; racemes bracted; calyx cut to base or nearly so; corolla blue, yellowish or white; corolla tube cylindrical, the imbricate lobes rounded and spreading or laxly ascending; throat with intruded ciliate or papillate appendages; stamens included, attached at middle of tube; filaments slender, short; anthers oblong; style slender, included in tube; stigmas geminate; ovules 4; mericarps 4, erect, ovoid or angulate, rugose or verrucose; areola inframedial or suprabasal, at lower end of ventral keel or terminating a downward-projecting stipitate prolongation of the keel springing from just above the base of the mericarps; gynobase flat to depressed-pyramidal.

The genus *Antiphytum* as here accepted includes about 10 Mexican species as well as 2 species in Brazil.

1. Pedicels not elongating, at most 5 mm. long; leaves in basal rosettes, alternate or only lowermost opposite; corolla tube practically undeveloped; appendages lacking ..
..... 1. *A. floribundum*.
1. Pedicels elongating, becoming 5-10 mm. long; leaves alternate only in the inflorescence; corolla with definite tube and faucal appendages ..
..... 2. *A. heliotropioides*.

1. *Antiphytum floribundum* (Torr.) Gray. Plant 3-12 dm. tall, a biennial or short-lived perennial, with a thick taproot, cinereous, finely antrorse strigose admixed with elongate slender usually spreading hairs that frequently arise from discoid or thickened bases; stems one to several, fistulous, stiffly erect, forming a straight central axis producing numerous stiffly ascending floriferous laterals, especially above the middle; leaves more or less conduplicate, narrowly oblanceolate, acute, the margin thickish and not at all revolute, to 2 dm. long and 1 cm. wide, lower surface with a thickened midrib, veinless, gradually smaller upward along the stem; inflorescence an elongate thyrsoid panicle; flowers at first in numerous small glomerules but at maturity elongating into loosely flowered unilateral racemose cymes to 1 dm. long; calyx at anthesis sessile or subsessile, 2.5-4 mm. long, the lobes lanceolate, acute, unequal, without a midrib, in fruit about 5 mm. long; corolla white, saucer-shaped, broader than long, scarcely if at all surpassing the calyx, widely expanding from the very base, 3-4 mm. long, 1.3 mm. in diameter at base. *Eritrichium floribundum* Torr., *Krynitzkia floribunda* (Torr.) Gray, *Amblynotopsis floribunda* (Torr.) Macbr. In Tex., confined to rocky soil in igneous areas in the Davis

Mts. (in Jeff Davis and n. Brewster cos.) and in the Chinati Mts. (Presidio Co.), July-Oct.; s. in Chih. and Dgo. to Jal. and Michoac.

An erect herb with tall virgate stems. It is summer-flowering and has saucer-shaped corollas with a short widely expanded open tube and hence completely exposed stamens, style and ovary. The corolla develops no faucal appendages.

2. *Antiphytum heliotropioides* A. DC. A slender-stemmed shrubby perennial, branched from the base, 1-4 dm. tall, with a pallid indument of stiffish appressed hairs; middle and lower cauline leaves opposite, oblanceolate, 1-4 cm. long; cymes terminal, becoming 5-15 cm. long, abundantly and loosely flowered, unilateral, bracteate, racemose; corolla salverform, tube cylindrical. Apparently confined to rocky calcareous soils and particularly common on limestone hillsides, questionably from near Marfa, Presidio Co., May-June; from Tex. (?) s. to cen. Mex.

The species is definitely known to occur on limestone hills about 50 miles south of the Texas border in both extreme eastern, as well as western sections of Coahuila, and is to be looked for in limestone areas north of the Rio Grande between Maverick and Presidio counties. Distinctive features aiding in recognizing the plant are its bushy fruticose habit and pale indument, opposite lower and middle cauline leaves, and the frequently very elongate pedicels on the fruiting calyces.

14. LITHOSPERMUM L.

GROMWELL. PUCCOON

Annual or perennial, herbaceous or fruticose plants with alternate leaves; flowers white, yellow or violet, in bracted racemes; calyx usually undivided; corolla tubular or salverform, the tube cylindrical, lobes spreading and imbricate, the throat with intruded appendages or with pubescent or glandular areas; stamens affixed in tube, included; filaments short; anthers oblong, usually with apiculate connectives; style filiform; stigmas geminate; ovules 4; mericarps 4 or rarely fewer, erect, ovoid or angular, smooth or verrucose, affixed by a broad horizontal or slightly oblique basal areola; gynobase flat or very broadly pyramidal.

A large genus with about 40 species in North America and 20 in the Old World. A purple dye was obtained by the Indians from the roots of these plants. The conspicuous corollas may be more or less sterile, and most of the seed may be developed from inconspicuous cleistogamous flowers produced later in the season.

1. Plant annual; corolla white1. *L. matamorensis*.
1. Plant perennial; corolla yellow, yellowish-white or orange (2)
- 2(1). Stems arising out of a basal cluster of leaves, the largest leaves at the base of the stem (3)
2. Stems arising from a bud on a caudex, root crown or rhizome, the largest leaves usually on the mid-section of the stem, the lowest leaves on the stem scalelike and very reduced (8)
- 3(2). Cauline leaves and bracts of the raceme oblanceolate to elliptic or ovate-elliptic (often broadly so) and usually acute; roots fusiform-thickened
.....2. *L. tuberosum*.
3. Cauline leaves and bracts of the raceme linear to linear-lanceolate or narrowly oblong and mostly obtuse; roots not noticeably fusiform (4)
- 4(3). Flowers heterostylic, none cleistogamic; corolla usually about as broad as long, funnellform, the throat unappendaged but abundantly stipitate-glandular, the tube villous inside; plant spreading by rhizomes, hence forming colonies
.....3. *L. cobrense*.
4. Flowers monomorphic, sometimes cleistogamic; corolla usually longer than broad, salverform, the throat with faucal appendages, only sparsely stipitate-glandular, the tube glabrous inside; plant with taproot (5)
- 5(4). Corolla lobes with the margins lobulate, lacerate or toothed; mericarps with a linear constriction above the base, smooth or pitted; pedicels of fruiting calyces of cleistogamic flowers evidently recurved4. *L. incisum*.
5. Corolla lobes entire or practically so; pedicels of all flowers remaining erect (6)

- 6(5). Mericarps smooth and shiny, white 5. *L. Parksii* var. *rugulosum*.
- 6. Mericarps roughened, dull-colored (7)
- 7(6). Mericarps covered with very crowded warts or irregular ridges or both; scar of mericarp excavated; basal leaves usually veinless ... 5. *L. Parksii* var. *Parksii*.
- 7. Mericarps coarsely pitted and coarsely tuberculate or subcornute on the shoulders; scar of mericarp flat, not excavated; basal leaves usually with a few evident veins 6. *L. mirabile*.
- 8(2). Flowers heterostylic; corolla tube not narrowly constricted at top (9)
- 8. Flowers not heterostylic; corolla tube cylindric, elongate, that is several times as long as the diameter of the proportionately small limb; corolla tube narrowly and distinctly constricted at the top (10)
- 9(8). Corolla about as long as broad, the limb 15-25 mm. in diameter, the tube cylindric; annulus evidently villous; flowers all subtended by bracts, never cleistogamic; plant hispid; stems scattered, arising from a rhizome 7. *L. carolinense*.
- 9. Corolla much longer than broad, the limb 8-9 mm. in diameter, the tube gradually ampliate at least above middle; annulus only very minutely and inconspicuously hairy; flowers mostly extra-axillary, sometimes cleistogamic; stems crowded in clusters, arising from a taproot 8. *L. multiflorum*.
- 10(8). Leaves all conspicuously veined, 8-32 mm. broad; plant 2.5-10 dm. tall; flowers all subtended by bracts; corolla lobes with entire margins 9. *L. viride*.
- 10. Leaves veinless, less than 10 mm. broad; plant 1-2.5 dm. tall; flowers mostly extra-axillary; corolla lobes with margins lobulate or erose-dentate and commonly also somewhat crisped 10. *L. calycosum*.

1. *Lithospermum matamorensis* A. DC. Annual, villose-hispid with spreading hairs and frequently also with an under pubescence of minute appressed hairs; root juicy when fresh; stems few, to 4 dm. long, very loosely branched, leafy, erect, ascending or decumbent, fistulose; leaves thin, hispid, with an evident midrib, the basal leaves oblanceolate, to 9 cm. long and 2 cm. broad, the apex obtuse or slightly retuse, cuneate or shortly petiolate at base, gradually reduced in size (elliptic to elliptic-oblanceolate) upward along the stems and on into the inflorescence; inflorescence simple or forked, circinate, in age straightening and becoming loosely flowered and to 25 cm. long; flowers small, numerous, borne in the axils of foliaceous bracts; calyx at anthesis 2.5-3.5 mm. long; calyx at maturity about 5 mm. long, the lobes herbaceous, linear or linear-oblanceolate; corolla small, white with a yellow center, total length 4-5.5 mm. long, very sparsely strigulose outside, the limb 4-7 mm. broad, the tube much shorter than the calyx; annulus usually 5-lobed; faucal appendages invaginate, puberulent, glandular on the side; fruit commonly maturing only a single mericarp; mericarps (when more than 1) more or less diverging, brownish, coarsely pitted, at times obscurely tuberculate, 2.5-3 mm. high. *L. prostratum* Buckl. On edge of thickets, in open woods and weedy areas in s. Tex. (s. to Balcones Escarpment and Guadalupe River), with outlying stations along the Colorado River in Travis and Llano cos. and along the Rio Grande and lower Pecos River in s.w. Val Verde Co., Feb.-May; Tex., Tam., N.L. and Coah.

2. *Lithospermum tuberosum* A. DC. Perennial, clothed with a spreading pubescence, to 7 dm. tall; cauline leaves somewhat smaller than the basal ones, to 1 dm. long and 25 mm. wide; inflorescence laxly few-flowered; bracts of the racemes similar to the cauline leaves but smaller; corolla yellow or yellowish-white, 4.5-6 mm. long, with a tube 3-4 mm. long, the lobes 1.5-2 mm. long, longer than broad and ascending; corolla throat with 5 small intruding velvety trapeziform appendages formed by invagination, below the appendages the throat is sparingly glanduliferous; calyx shorter than the corolla tube or at most equal it in length; filaments attached at the middle of the corolla tube and without glands at their base; nectary a narrow glabrous flange; mericarps small, 1.5-2.5 mm. long, often abundantly punctate. In low often dry woods in e. Tex., Mar.-Apr.; scattered along the Coastal Plain and in adj. provinces from Fla. to Tenn. and Tex.

This species is readily recognized by its rosette of large basal leaves and its fleshy fusiform roots.

3. *Lithospermum cobrense* Greene. Perennial, early in the season producing radical leaf clusters from which later the flowering stems arise; stems erect, one to several, to 6 dm. tall, simple or sometimes with ascending branches above the middle, strigose or sparsely hispid with hairs 1-3 mm. long; basal leaves usually dried up and frequently disappearing before anthesis, oblanceolate, to 1 dm. long and 16 mm. wide; cauline leaves very numerous, crowded, much smaller than the basal ones, narrowly oblong to linear, obtuse, sessile, to 35 mm. long, and 5 mm. wide; inflorescence circinate, terminal, simple or sometimes forked, infructescence of stiff, erect, loosely flowered, unilateral racemes 1-2 dm. long; flowers mostly clearly extra-axillary; calyx at anthesis 5-7 mm. long, the lobes oblong-linear, very unequal; pedicels 1-3 mm. long; calyx in fruit 6-10 mm. long; corolla with a cylindric tube and abruptly expanding throat and limb, pale-yellow, darkening in drying, minutely pubescent outside, the limb 15-20 mm. in diameter, the lobes suborbicular, spreading, 5-6 mm. in diameter, the margins entire; tube cylindric, about 8 mm. long and 3-4 mm. thick; annulus well-developed, consisting of 10 quadrate lobes. In Tex. known only from grassy open places in the Davis Mts., June-Aug.; Tex., N.M. and Ariz., s. to Chih. and Dgo.

4. *Lithospermum incisum* Lehm. Perennial, smoothly strigose with the hairs usually closely appressed but at times somewhat loosely so; root crown first developing a cluster of basal leaves and later one to many erect stems to 3 dm. tall, these at first simple but becoming branches later in the season; basal leaves to 12 cm. long and 1 cm. wide, oblanceolate, usually broader but not always longer than the lower cauline leaves, commonly dried up and frequently disappearing before flowering time, the apex acute; cauline leaves numerous, gradually and very moderately reduced in size upwardly along the stem, linear to lance-linear, commonly 3-6 cm. long and 3-6 mm. broad, frequently hispid-ciliate towards the base; *inflorescence produced in the spring of the year*, consisting of leafy-bracted terminal clusters of usually sterile flowers with very conspicuous yellow trumpet-shaped corollas; calyx at anthesis 7-12 mm. long, the lobes slender and unequal; pedicels 1-4 mm. long, erect; corolla salverform, sparingly strigose outside, the tube 15-35 mm. long, slender, gradually ampliate above the middle, the limb 9-20 mm. in diameter; *in late spring and summer* only minute cleistogamic flowers are developed by the plant which becomes much-branched and very leafy, and changes its growth-form, the basal leaves entirely disappearing and the stem leaves becoming very numerous, narrowly linear or lance-linear and mostly smaller, usually only 2-3 cm. long and 1.5-3 mm. broad; cleistogamic flowers very numerous and extremely fertile, borne hidden among bracts terminal on the stems, branches and branchlets; corolla permanently closed, 1-2.5 mm. long, tubular, the tube glabrous with the rounded summit hairy; calyx of cleistogamic flowers at first 2-6 mm. long, subsessile, at maturity 5-7 (-8) mm. long, usually borne in some numbers along the leafy stems and branches; pedicels usually 2-4 mm. long. *L. breviflorum* Engelm. & Gray. Generally distributed throughout most of Tex. in various types of habitats but usually in sandy soils of prairies, fields and open-wooded areas, Nov.-June; widely distributed in the U.S., chiefly on the Great Plains and along the Rocky Mts., and extending into adj. Can. and Mex.

Plants of western Texas average lower (1-2 dm.) than those for the central and eastern parts of the state. The conspicuous open corollas also are smaller and less fertile, the late-season cleistogamic form is more bushily branched and more fertile, and the mericarps are more abundantly pitted and average slightly smaller in western plants than in those for farther east in Texas.

5. *Lithospermum Parksii* I. M. Johnst. var. *Parksii*. Perennial, early in the year producing a basal cluster of leaves out of which the flowering stems later arise, the herbage somewhat olivaceous, with loosely appressed hairs; stems one to several, to 5 dm. tall, at first simple but usually becoming more or less loosely and ascendingly branched in age; basal leaves to 9 cm. long and 13 mm. wide, commonly dried up at anthesis, oblanceolate, the apex obtuse or rounded; cauline leaves numerous, narrower and shorter than the basal leaves and very gradually reduced in size upwardly along the stem, the middle ones usually 3-6 cm. long and 2-5 mm. broad, linear or oblanceolate-linear, the margins somewhat revolute; inflorescence producing only flowers with conspicuous corollas or

sometimes also cleistogamic flowers at the end of the season or only cleistogamic flowers, terminal, circinate, simple or sometimes forking, in fruit lengthening to form stiff, erect, loosely flowered unilateral racemes 1-2 dm. long; the normal flower with conspicuous corolla varying greatly in size; calyx at anthesis 4-12 mm. long, in fruit 9-15 mm. long; corolla salverform, yellow, the limb spreading, 7-20 mm. in diameter, finely strigose outside; mericarps usually 3 mm. high when measured along the ventral keel, the convex back about 2 mm. broad, base of mericarp opaque; attachment surface triangular, about 1.7 mm. broad, in completely mature mericarps its surface collapsing and tissue inside the basal collar of the mericarp apparently excavated, the tissue surrounding the funicular canal forming a spurlike projection 0.5-0.7 mm. long arising from the depths of the excavated base. On limestone in Sutton, Edwards and Kinney cos. w. to Glass and Del Norte mts., Brewster Co., and also in the Guadalupe Mts. of Culberson Co. and adj. Eddy Co., N.M., Mar.-Aug.

Var. *rugulosum* I. M. Johnst. Agreeing with var. *Parksii* in all details except fruit; mericarps larger and more plump, smooth and shiny when mature except for some pits and slots on the venter, particularly along the base of the ventral keel, the body 2.5-3.5 mm. long measured along the ventral keel, 2-2.5 mm. broad across the convex back, body gradually narrowed to the base or gradually narrowed down to about 0.4-0.5 mm. above the base and thereafter more abruptly so and thus giving some of the mericarps a suggestion of a basal collar; attachment surface depressed, surrounded by projecting pericarpial walls 0.2-0.5 mm. high, the depression not formed by the break-down of tissue, the depressed surface with a pit in the ventral angle and a wart near the middle, no projecting spur developed. Four stations in Tex.: Real Co., Sierra Madera (Pecos Co.), Glass Mts. (Brewster Co.) and Guadalupe Mts. (Culberson Co.). At the last three localities mentioned it is associated with var. *Parksii*.

6. *Lithospermum mirabile* Small. Perennial, taproot slenderly clavate, its cortex dark in color from contained dye, usually grayish from a strigose indument, the hairs slender; stems erect, to 4 dm. tall, one to several, usually unequal and forked in the inflorescence and with several slender branches from below the middle; basal leaves clustered, usually persisting even on fruiting plants, oblanceolate, to 7 cm. long and 13 mm. wide, lower surface with a prominent densely strigose midrib and commonly with one or two well-developed assurgent veins; cauline leaves numerous, gradually reduced upwards along the stems, the middle ones usually linear-oblong, sessile, obtuse, to 4 cm. long and 3-5 mm. wide; inflorescence terminal on the stems and branches, stiffly circinate; flowers at first bunched at the summit of the stems, in fruit scattered along single or forked lengthening stiffly racemose cymes to 15 cm. long; producing first conspicuous perfect flowers and late in the season also cleistogamous flowers or sometimes only the latter; normal conspicuous flowers with corolla dark-yellow, salverform, outside sparsely strigose or appressed villulose, the limb 8-14 mm. in diameter, the tube 10-18 mm. long, slender; calyx 6-8 mm. long at anthesis, the lobes lanceolate, unequal, in fruit about 8 mm. long. *L. longiflorum* A. DC. var. *mirabile* (Small) Brand. In arroyos, open woods and brushlands of s. Tex., chiefly in Bexar Co. southw., Mar.-May; endemic.

This species is related to *L. incisum* but is readily distinguished by its coarsely tuberculate mericarps, the persisting commonly veined basal leaves, and entire-margined corolla lobes. The corolla is a deep-yellow and the plant has a distinctive grayish color because of its pubescence.

7. *Lithospermum caroliniense* (Walt.) MacM. Puccoon. Perennial, hispid, commonly becoming very dark in drying; arising from a deep strong usually dye-stained taproot; stem erect, 3-10 dm. tall, few to numerous, simple or commonly branched only in the inflorescence, bearing minute appressed hairs and also larger spreading hairs 1-2 mm. long; leaves numerous, lanceolate or sometimes lance-linear, sessile, usually acute, hispid, to 4 cm. long and 1 cm. wide; inflorescence terminal, circinate, simple to geminate or ternate, in age elongating, straightening and becoming 1-2 (-3) dm. long, loosely flowered; bracts commonly ovate or elliptic, acute; calyx at anthesis 6-8 mm. long, the lobes very unequal, lanceolate, herbaceous, the fruiting calyx 8-10 mm. long, the pedicel 3-5 mm. long, erect; corolla orange-yellow, salverform, sparsely villose-hispidulous outside; mericarps lustrous, white, usually smooth except for some pits and slots along the base of the ventral keel, plump ovoid, 3-3.5 mm. long. *L. bejariense* A. DC. In sandy

woods, from e. pine forests w. to the Western Cross Timbers and s. to Wilson Co. on the Coastal Plain, also local in the Panhandle (Hemphill, Briscoe and Wheeler cos.), Mar.-May; widely distributed in the e. half of the U.S.

8. *Lithospermum multiflorum* Gray. Perennial, arising from a small compact caudex crowning a strong deep taproot; stems erect, 2-5 dm. tall, few to numerous, simple or (especially late in the season) becoming ascendingly branched above the middle; indument thin, grayish, closely appressed or ascending, the hairs stiffish and frequently arising from mineralized bases; leaves numerous, green, pale beneath, the margins slightly thickened and usually not revolute, leaves on the middle third of stem the largest, sessile, lanceolate to lance-linear, to 7 cm. long and 9 mm. wide, usually at least twice the size of the lower and upper leaves on the stem; inflorescence simple or forked, terminal on the stems and branches, the flowers with conspicuous corollas opening only on the tight circinate summit, at maturity (usually maturing few nutlets) elongating and (especially when unusually fertile) forming stiff erect loosely flowered racemes to 15 cm. long, late in the season usually producing some inconspicuous but very fertile cleistogamic flowers; calyx of normal flowers 4-6 mm. long at anthesis, the lobes linear, very unequal, the fruiting calyx 6-10 mm. long; pedicels 3-8 mm. long, erect; corolla orange-yellow, longer than broad, usually narrowly funnelform above the middle, appressed-villulose outside; tube cylindric or more commonly ampliate from the middle (or even the base) upwards, 8-10 mm. long, 2-3 mm. thick, the limb 8-9 mm. broad; mericarps ovoid, rarely more than one maturing in each fruit, white or brownish, usually smooth except for some slots and pits along the ventral keel, 2.5-3.5 mm. high (measured along the ventral keel). Chiefly in the pine-belt in the Chisos, Davis, Guadalupe and Franklin mts. in the Trans-Pecos, June-Sept.; Chih. to Wyo.

9. *Lithospermum viride* Greene. Perennial, arising from a small suffrutescent caudex crowning a woody taproot; stems few to numerous, to 1 m. tall, erect, 3-5 mm. thick just above the base, simple or loosely and ascendingly branched in age, usually with a grayish indument made up of 2 types of hairs, the more abundant type spreading or retrorsely appressed and the less abundant more rigid type spreading or ascending; largest leaves near the middle of the stem to 8 cm. long and 32 mm. wide, ovate-elliptic to lanceolate, the apex acute, the upper surface scabrous with stiff erect bristles arising from discoid bases intermixed with shorter much less rigid hairs, the lower surface paler and somewhat velvety or strigose; inflorescence simple or forked, terminal on the stems and branches, circinate, in age elongating, straightening to form erect very loosely flowered racemes 1-3 dm. long; calyx at anthesis 8-13 mm. long, the lobes very unequal, linear, the fruiting calyx 10-18 mm. long; pedicel 2-10 mm. long, ascending or occasionally decurved, lobes lance-linear; corolla greenish-yellow, with a very small limb, villose-hispidulous outside; corolla tube cylindric, 1-3 cm. long, 3-5 mm. thick near the middle, inside glabrous except for the abundant stipitate glands in the constricted apical section, no faucal appendages developed; annulus a thickened 10-lobed ring bearing extremely minute tufts of hairs; corolla lobes ovate to elliptic, rounded, entire, spreading or usually recurved; mericarps ovoid, usually plump, white or somewhat brownish, smooth or obscurely pitted, almost always with some pits along the base of the ventral keel, 3.5-4.5 mm. high (measured along the ventral keel). Usually in limestone areas in the Glass, Del Norte, Chisos and Guadalupe mts. in the Trans-Pecos, May-Sept.; N.M., Tex., Coah. and N.L.

10. *Lithospermum calycosum* (Macbr.) I. M. Johnst. Perennial, with a coarse woody taproot; stems several, 10-25 cm. tall, erect, simple or sparingly branched above the middle, below the middle hispidulous, above the middle with almost all the hairs antrorsely appressed; largest leaves oblanceolate, to 3.5 mm. long and 8 mm. wide, obtuse or retuse, appressed-hispidulous; inflorescence simple, terminal, circinate; calyx at anthesis 6-7 mm. long, the pedicels strigose and 1-3 mm. long, the lobes extremely unequal, linear or linear-oblanceolate; corolla "pale dull yellow-cream," with an elongate tube and a relatively small limb, the tube 8-10 mm. long, surpassing the calyx 3-5 mm., strigose outside, inside glabrous except for stipitate glands at the summit. Known in the U.S. only from a single collection made high on Chinati Peak in w. Presidio Co.; Tex., Coah. and N.L. s.e. to Guat.

15. BUGLOSSOIDES MOENCH

About 15 species native to Eurasia.

1. *Buglossoides arvensis* (L.) I. M. Johnst. Annual; stems erect, 2-7 dm. tall, simple or sparsely branched above, hoary-strigose; leaves 2-5 cm. long, 2-8 mm. broad, closely appressed-hispid, firm, veinless, with prominent midrib, pale beneath; basal leaves rosulate, oblanceolate or spatulate, those of the mid-stem lanceolate or linear and acute; racemes bracted, becoming loosely flowered; pedicels short and stout, about 1 mm. long; calyx parted into subulate-linear lobes, hispid; mature calyx with the erect or ascending lobes becoming 8-13 mm. long, the very short tube oblique, pale and chartaceous; corolla white or yellowish or even purplish, 5-7 mm. long, tubular-funnelform, the tube glabrous within and scarcely if at all surpassing the calyx; corolla throat gradually expanded, without protuberances, merely puberulent; corolla lobes ascending, ovate, obtuse; mericarps brown, dull, roughened, tuberculate or rough-wrinkled or pitted, about 3 mm. long, triquetrous-ovate, the ventral keel prominent. *Lithospermum arvensis* L. In open woodlands, old fields and waste places generally in the e. half of Tex.; a Eur. plant, widely introd. in the U.S., adj. Asia, Afr. and S.A.

The bony, hard, rough mericarps are straight and have a broad basal attachment which tends to become oblique.

16. ONOSMODIUM MICHX. FALSE-GROMWELL. MARBLE-SEED

Plants erect, rough-hairy, branching, very leafy perennials from taproots, with alternate, entire, strongly veined leaves, and numerous flowers in terminal, leafy-bracted scorpioid cymes; flowers whitish, greenish-white or yellowish, sessile to shortly pedicellate; pedicels usually somewhat elongating in fruit; calyx shorter than the corolla, deeply 5-parted; corolla tubular, slightly enlarged at the throat, 5-lobed, glabrous within, more or less hairy outside, the lobes erect, acute or acuminate, the sinuses somewhat inflexed; stamens included; filaments minute; anthers glabrous, narrowly sagittate, acutish, the apex just about level with the sinuses of the corolla; ovary 4-parted; style filiform, exerted, long-persistent; mericarps 4 mm. long or less, usually but one or two maturing, globular to ovoid, smooth or sometimes sparingly pitted, white to dingy-whitish-brown, in some species noticeably constricted below, attached at base to the nearly flat receptacle, the scar attachment about 2 mm. wide.

About 15 species in the United States, Canada and Mexico.

- 1. Stems usually solitary; basal rosette usually persisting (at least dried) till anthesis; usually more southern (2)
- 1. Stems usually several, tufted, arising from a strong perennial root; basal leaves not persisting; usually more northern (3)
- 2(1). Plant fully developed at anthesis; leaves finely strigose below (bristles few) and on upper surface with strigose hairs (0.2-0.4 mm. long) under pubescence at least on either side of veins and with coarse bristles (1-2 mm. long) either appressed or spreading; pedicels short, less than 7 mm. long; bracts lanceolate, not greatly accrescent 1. *O. bejariense*.
- 2. Plant flowering while stem and herbage still fresh and incompletely developed; leaves completely lacking strigulose indument, only bristles about 1 mm. long and erect or ascending on leaves (top or bottom); pedicels elongate, the lower ones commonly 10-15 mm. long; at maturity bracts much-enlarged, ovate or elliptic 2. *O. Helleri*.
- 3(1). Mericarps strongly constricted at the base; plant always coarsely spreading-hirsute 3. *O. hispidissimum*.
- 3. Mericarps with base rounded or if weakly constricted the plant somewhat silky-hirsute 4. *O. occidentale*.

1. *Onosmodium bejariense* A. DC. Plants 6-9 dm. tall; stem branching above, the branches ascending, strongly hispid-pubescent with white or whitish hairs, the branches

also softly appressed-pubescent; leaves lanceolate or the lower oblanceolate-spatulate, the well-developed stem leaves to 13 cm. long and 14 mm. wide, acute, sessile, strongly 5- to 7-nerved, the nerves prominent on both surfaces; calyx lobes linear-lanceolate, 8-10 mm. long, acute, appressed-pubescent and long-ciliate at base; well-developed corollas 14 mm. long, very finely canescent outside, often appearing nearly glabrous, with a few spreading hairs on the lobes; corolla lobes 3-4 mm. long, triangular in outline, tapering to a long-acuminate often abruptly bent apex; mericarps 3 mm. long, obtusish or acutish, from little to quite noticeably constricted at base. In dry open woodlands and on open hillsides, w. to Tom Green and Uvalde cos., e. to Gonzales and Cherokee cos., Mar.-June; endemic.

2. *Onosmodium Helleri* Small. Plants 3-4 dm. tall, drying black and brown, short-pubescent all over with scattered hairs or densely soft-pubescent on the leaves beneath; leaves broad, large, obtusish, short-petioled, 8-10 cm. long, 3-5 cm. wide, the upper leaves and bracts more ample than basal leaves, the lower leaves broadly spatulate and tapering to the base, the middle leaves broadly oblong-elliptic and rounded at the base; bracts broadly ovate (at least the lower ones), obtuse; calyx lobes 7-10 mm. long, linear, obtusish, ciliate; corolla lobes more or less acuminate, about as long as tube, 8-10 mm. long; mericarps obtusish; 3 mm. long, apparently not constricted at base. Edwards Plateau, cen. Tex., in thickets and woodlands, Mar.-May; endemic.

Recognizable by the short-petioled leaves.

3. *Onosmodium hispidissimum* Mack. Plant 9-12 dm. tall, strongly branched above, the branches spreading or ascending; stems and branches thickly covered with spreading hispid whitish (or in the inflorescence yellowish-white) hairs 2-4 mm. long, the branches and often the stem also appressed-pubescent; leaves typically lanceolate, 8-10 cm. long, 14-25 mm. wide, acute or acutish, tapering to the sessile base, prominently 5- to 7-nerved on both surfaces, strongly covered with whitish or sometimes yellowish-white spreading papillose hispid hairs above and on the veins beneath and appressed-strigose between the veins beneath; bracts 8-16 mm. long, resembling the leaves in outline; fruiting pedicels to 4 mm. long; calyx lobes linear-oblong, obtuse, 4-6 mm. long, strongly hispid with yellowish-white hairs; corolla (in earlier flowers, at least) 14-18 mm. long, twice the length of the flowering calyx, sparingly canescent outside below the lobes but usually strongly canescent and with strongly developed tufts of hairs at the tip of the broadly triangular-acute lobes that are about 3 mm. long; mericarps 2-3 mm. long, very obtuse to acutish, strongly constricted at base, dull, little if at all pitted. Usually in gravelly or rocky calcareous soils in prairies, on banks and in openings of glades, rare in n.-cen. Tex. (Dallas Co., where last collected in 1880), Mar.-May; from N.Y. s. to Md., w. to La., Tex. (?) and Neb. Perhaps not a persistent member of our flora.

4. *Onosmodium occidentale* Mack. Plant 3-6 dm. tall, rarely more, branching above or often from near the base, the branches spreading or almost erect, clothed all over with silvery-white or sometimes a slightly yellowish appressed or more or less spreading canescent pubescence usually not exceeding 2 mm. in length, the pubescence of the branches and leaves usually appressed; leaves typically about 5 cm. long and 15 mm. wide, acutish, prominently 5- to 7-nerved on both surfaces, the pubescence sometimes strongly spreading and papillose, but most typically soft, appressed and hardly papillose; bracts 6-24 mm. long, often 2-ranged, resembling the leaves in outline; fruiting pedicels from very short to 6 mm. long; calyx lobes lanceolate, acute to obtusish, rarely linear-oblong, 6-12 mm. long, canescent or with somewhat spreading hairs; corolla 1.2-2 cm. long, canescent all over outside, the broadly triangular acute lobes (3-4 mm. long) usually with apical tuft of hairs not strongly noticeable; mericarps 3.5-4 mm. long, acutish or acute, not constricted at base, dull in color, little if at all pitted. *O. molle* Michx. var. *occidentale* (Mack.) I. M. Johnst. Usually in open rocky woods, prairies, bottomlands and on hillsides from Denton, Grayson and Lamar cos., s. to Bexar, Victoria and Jackson cos., Apr.-June; from Minn. and Ill., w. to N.M., Ut. and Sask.

Those plants occurring from Tarrant County south typically have smaller leaves that are less hirsute and frequently strigose, whereas those occurring northward are usually coarse and hispid.

17. ECHIUM L. VIPER'S BUGLOSS

A complex genus of about 40 species in the Old World with several species introduced in the New World.

1. *Echium vulgare* L. BLUE-WEED. Biennial herb; stems erect, solitary or occasionally several, 3-9 dm. tall, finely hispid-villous as well as shaggy coarse-hirsute; leaves alternate, appressed-hispid and along the margins and midrib somewhat hirsute, with a strong midrib but very obscure or absent veins; lower leaves 8-16 cm. long, oblanceolate, broadly stalked, forming a rosette that withers away at anthesis; cauline leaves reduced up the stem, the middle ones linear-lanceolate, 3-9 cm. long, contracted to a rounded sessile base; racemes unilateral, short, bracteate, disposed in a long narrow thyse or open panicle; calyx 5-parted with linear or lanceolate segments; corolla tubular-funnelform, oblique and irregular, bright-blue, rarely rose or white, pubescent and sparsely setose, rather firm in texture, 10-15 mm. long, the tube about equaling the calyx; stamens very unequal, inserted low in the tube, the 2 pairs slightly unequal but both surpassing the lower corolla lobe, the odd stamen included; mericarps 4, about 2 mm. long, erect, rugose or verrucose, ovoid or oblong, with a basal areola; gynobase flat or low-pyramidal. Nat. of Eur., long ago introd. into e. U.S. and now a serious pest in the N.E. and Middle Atl. States, w. to S.D., Kan. and reported (but not seen by us) from Tex.; also Chile.

FAM. 156. AVICENNIACEAE ENDL.¹⁵⁸

BLACK-MANGROVE FAMILY

Shrubs or trees of maritime regions; branches and twigs usually terete, nodose, articulate; leaves opposite, thick, persistent, petiolate, exstipulate, entire; inflorescence axillary or terminal, spicate or subcapitate, the axillary ones mostly paired; flowers sessile, perfect, hypogynous, small; sepals 5, nearly separate, ovate, imbricate, subtended by a false involucre of a scalelike bract and 2 alternate scalelike prophylla slightly shorter than the calyx and imbricate with each other and the sepals; corolla regular, gamopetalous at the base, campanulate-rotate, 4-parted; stamens 4, inserted in the corolla tube, equal or subdidynamous; carpels 2; ovary superior, compound but with a free central often more or less 4-winged placenta; ovules 4, pendent, orthotropous, hanging from the tip of a central columella; fruit a compressed oblique capsule, the exocarp juicy, somewhat fleshy, usually tomentulose, dehiscent by 2 valves, usually only 1-seeded; seeds without a testa; embryo viviparous.

A single genus with 11 living species, 5 varieties, and 4 fossil species; one of the chief constituents of coastal mangrove belts throughout the tropics and subtropics of the world.

1. AVICENNIA L.

1. *Avicennia germinans* (L.) L. BLACK-MANGROVE, MANGLE BLANCO. Shrub rarely over 1 m. tall in our area (to 16 m. in tropics); petioles 2-27 mm. long, often farinaceous; leaf blades oblong or lanceolate to elliptic or obovate, to 15 cm. long and 44 mm. wide, obtuse or acute at the apex, entire, acute to cuneate at the base, usually grayish-mealy beneath, sometimes glabrous and punctate; spikes to 65 mm. long and 15 mm. wide during anthesis, the axillary ones usually only a single pair at the base of the terminal one and shorter than it or a second pair in the next lower leaf axils; calyx lobes 3-5 mm. long, 2-3 mm. wide, densely appressed-pubescent outside, glabrous within; corolla white, 1.2-2 cm. long, parted to about the middle, the tube equaling or shorter than the calyx, practically glabrous, the lobes spreading, densely gray-pubescent outside and velvety within; fruit obpyriform or ovate, asymmetric, to 2 cm. long and 12 mm. wide, densely

¹⁵⁸ Contributed by H. N. Moldenke; cf. his earlier treatment in C. L. Lundell, *Flora of Texas* III: 10-12. 1942.

gray-hairy. *A. nitida* Jacq. In mangrove lagoons and along tidal shores, s.e. and s. Tex.; very variable, ranging from Fla. and Tex., Berm., Bah. I. and both coasts of Mex., through W.I. and C.A. to the coasts of Braz. and Peru.

The fruits of the red mangrove, *Rhizophora Mangle* L. (Rhizophoraceae), of southern Florida and tropical America, are commonly washed ashore (especially near the mouth of the Rio Grande), where they have been known to sprout, but no living plant has apparently thus far become established in Texas. This species grows in habitats similar to those of the black mangrove but it is readily distinguished from that species by its aerial roots that arise from its trunk and branches, its regular corolla, and the development of a conspicuous radicle to several decimeters in length.

FAM. 157. VERBENACEAE ST.-HIL.¹⁵⁹

VERVAIN FAMILY

Herbs, shrubs, woody vines or trees; branchlets and twigs mostly tetragonal, not prominently nodose nor articulate; leaves mostly opposite, deciduous, exstipulate, mostly simple, sometimes compound or 1-foliolate, the blades entire or variously dentate, incised or cleft; inflorescence axillary or terminal, determinate or indeterminate, as cymes, racemes, spikes, panicles, thyrsi, heads or false umbels, sometimes involucrate, the axillary ones mostly solitary; flowers sessile or pedicellate, perfect or imperfect, hypogynous, sometimes heterostylous or polygamous, large or small, mostly irregular, the individual ones not involucrate; calyx gamosepalous, campanulate to tubular or salverform, persistent, usually accrescent, mostly 4- (more rarely 2-, 5- or 7-) lobed or toothed or sometimes the rim subentire; corolla regular or irregular, gamopetalous, mostly funnelliform or salverform, usually with a well-developed tube with its limb 4- or 5- (rarely 7- or many-) parted, often somewhat 2-lipped; stamens mostly 4 and didynamous or reduced to 2, sometimes 4 or 5 and equal, inserted in the corolla tube; staminodes often present; carpels mostly 2 (rarely 4 or 5), united, one sometimes aborted; ovary superior, mostly compound, sessile, mostly somewhat 4-lobed, at first 2- to 5-celled but almost invariably soon becoming 4- to 10-celled through formation of false partitions, never with a free central placenta or columella; the axile placentae-lobes each bearing 1 ovule, the unpartitioned cells 2-ovulate, partitioned cells 1-ovulate; ovules anatropous and basal or hemianatropous and lateral; fruit usually a dry schizocarp separating into "cocci" at maturity or less commonly a drupe or fleshy schizocarp, with a thin and dry or fleshy exocarp and more or less hard endocarp, 2- to 4-celled and indehiscent when ripe or dehiscent into 2 (or rarely 4 to 10) 1- or 2-celled pyrenes; seeds plainly testate; embryo not viviparous.

About 3,375 species and subspecific taxa in 76 genera, very widely distributed almost throughout the world except in the Arctic and Antarctic.

1. Leaves palmately compound 12. *Vitex*, p. 1339.
1. Leaves simple (2)
- 2(1). Inflorescence indeterminate and centripetal, racemose (3)
2. Inflorescence determinate and centrifugal, cymose (12)
- 3(2). Fruit composed of four 1-seeded pyrenes, schizocarpous (4)
3. Fruit not composed of four 1-seeded pyrenes (5)
- 4(3). Pyrenes (cocci or nutlets) readily separating from each other at maturity 1. *Verbena*, p. 1313.
4. Pyrenes adhering or very tardily separating from each other at maturity 2. *Stylodon*, p. 1326.
- 5(3). Fruit composed of one or two 1-celled and 1-seeded pyrenes (6)
5. Fruit composed of two or four 2-celled and 2-seeded pyrenes (10)
- 6(5). Fruit usually with a fleshy exocarp (rarely dry); calyx truncate or obscurely toothed or lobed 3. *Lantana*, p. 1326.
6. Fruit with a thin dry exocarp; calyx deeply 2- to 5-toothed or -lobed (7)

¹⁵⁹ Contributed by H. N. Moldenke; cf. his earlier treatment in C. L. Lundell, *Flora of Texas* III:13-87. 1942.

- 7(6). Calyx elongated, conspicuous, herbaceous, often half as long as the corolla tube or longer; fruit (cocci) beaked 7. *Bouchea*, p. 1335.
7. Calyx very small and inconspicuous, membranous; fruit not beaked (8)
- 8(7). Flowers and fruit scattered at conspicuous intervals along a greatly elongated flowering rachis 6. *Aloysia*, p. 1334.
8. Flowers and fruit very densely imbricate, often capitate (9)
- 9(8). Mostly herbaceous with trailing or ascending stems, sometimes somewhat woody; spikes elongated in fruit; bractlets cuneate-obovate, not 4-ranked 5. *Phyla*, p. 1331.
9. Erect bushes, shrubs or subshrubs; spikes not usually elongating in fruit; bractlets ovate or lanceolate, often more or less 4-ranked 4. *Lippia*, p. 1330.
- 10(5). Fruiting calyx patelliform or cupuliform, not inflated nor enclosing the fruit nor rostrate at the apex 9. *Citharexylum*, p. 1337.
10. Fruiting calyx flask-shaped, completely enclosing the mature fruit, usually rostrate at the apex (11)
- 11(10). Herbaceous; fruit dry, composed of 2 pyrenes 8. *Priva*, p. 1337.
11. Woody; fruit fleshy, composed of 4 pyrenes 10. *Duranta*, p. 1338.
- 12(2). Flowers regular; stamens equal 11. *Callicarpa*, p. 1339.
12. Flowers irregular; stamens didynamous (13)
- 13(12). Fruit very strongly and coarsely reticulate, pubescent, with a definite rugose commissural scar 14. *Tetraclea*, p. 1341.
13. Fruit glabrous, not reticulate 13. *Clerodendrum*, p. 1340.

I. VERBENA L.

VERVAIN

Herbs; stems and branches procumbent, ascending or erect, glabrous or variously pubescent; leaves mostly opposite, dentate (very rarely entire) or variously lobed, incised or pinnatifid; inflorescence spicate, terminal, usually densely many-flowered, often flat-topped and pseudo-umbellate, sometimes greatly elongate with scattered flowers, very rarely also axillary; flowers small or medium-sized, each solitary in the axil of a usually narrow bractlet; calyx usually tubular, 5-angled, 5-ribbed, unequally 5-toothed, not at all or but slightly changed in fruit; corolla salver- or funnelform, its tube straight or curved, often slightly ampliate at the apex, the limb flat, weakly 2-lipped, lobes 5, usually rather elongate, obtuse or rounded to emarginate at apex; stamens 4, didynamous, inserted in the upper half of the corolla tube, mostly included; anthers ovate, with parallel or slightly divergent thecae, the connective unappendaged or glandular-appendaged; style single, usually short, shortly 2-lobed, the posterior lobe smooth, the anterior lobe broader, papillose and stigmatic; ovary 2-carpellary, 4-lobed, completely 4-celled, 4-ovulate; fruit mostly enclosed by the mature calyx, schizocarpous, readily separating at maturity into four 1-seeded linear cocci.

A complex genus of about 206 species, 122 named varieties and forms, and 49 named hybrids, mostly of temperate and tropical America; 2 or 3 species native to the Mediterranean region and introduced elsewhere in the Old World; many are widely cultivated and tend to escape. The Section Glandularia, with a different basic chromosome number, is possibly worthy of segregation as a distinct genus.

1. Sterile style lobe usually not protruding beyond the stigmatic surface; ovary entire or very shallowly depressed; schizocarp commonly not constricted along the lines of cleavage; anthers unappendaged; corolla mostly small, often not showy; calyx rarely more than twice as long as the schizocarp, not contorted beyond it. (Sect. 1. *Verbenaca* Schauer) (2)
1. Sterile style lobe protruding well beyond the stigmatic surface; ovary in its later stages definitely (although shallowly) lobed at the distal end; schizocarp constricted along the lines of cleavage; connective of the upper anthers mostly appendaged; corolla mostly large and showy; calyx usually more than twice as long as the schizocarp and constricted or contorted beyond it. (Sect. 2. *Glandularia* Schauer) (36)

- 2(1). Heads or spikes crowded and short (at least during anthesis), not at any time greatly elongate or open, generally disposed in compound cymes. (Ser. 1. *Pachystachyae* Schauer) (3)
2. Spikes slender and open or compact at anthesis, greatly elongating in fruit, solitary or in simple cymes or panicles. (Ser. 2. *Leptostachyae* Schauer) (5)
- 3(2). Leaves semiamplexicaul and subcordate at the base (4)
3. Leaves tapering into a cuneate-attenuate sessile or petiolar base 4. *V. brasiliensis*.
- 4(3). Inflorescence glandular; bractlets conspicuously longer than the calyx; corolla tube 2 or 3 times as long as the calyx 1. *V. rigida*.
4. Inflorescence not glandular; bractlets barely equaling or only slightly surpassing the calyx; corolla tube scarcely twice as long as the calyx 2. *V. bonariensis*.
- 5(2). Spikes paniced at the apices of the stems and branches, subtended chiefly by inconspicuous bracts; floral bractlets not prominent (6)
5. Spikes solitary or in 3's at the apices of stem and branches or paniced and subtended by leafy bracts at the base; floral bractlets often conspicuous (16)
- 6(5). Leaves sessile to sessile or long-tapering at the base 3. *V. litoralis*.
6. Leaves distinctly petiolate (7)
- 7(6). Spikes very slender, elongate and graceful, usually with remote fruits (8)
7. Spikes thicker and dense-flowered, usually with contiguous fruits (15)
- 8(7). Lower leaves 1- or 2-pinnatifid, 3- or 5-cleft or deeply incised (9)
8. Leaves merely serrate or crenate (12)
- 9(8). Schizocarp a little longer than broad; leaves all deeply cleft or incised 5. *V. menthaefolia*.
9. Schizocarp about twice as long as broad; leaves diverse, the basal incised-dentate, the middle stem leaves 1- or 2-pinnatifid, the upper sparingly toothed or entire (10)
- 10(9). Corolla white 6. *V. Halei* f. *albiflora*.
10. Corolla not white (11)
- 11(10). Corolla mostly blue 6. *V. Halei*.
11. Corolla deep-rose or pink 6. *V. Halei* f. *roseiflora*.
- 12(8). Leaves very scabrous above; fruiting calyx spreading; calyx lobes connivent; stigmatic surface subtended by 2 sterile style lobes (13)
12. Leaves not pronouncedly scabrous above; fruiting calyx ascending; calyx lobes not connivent; stigmatic surface subtended by one sterile style lobe (14)
- 13(12). Leaf blades ovate, to 5 cm. wide 7. *V. scabra*.
13. Leaf blades narrowly elliptic or elliptic-lanceolate, to 2 cm. wide 7. *V. scabra* f. *angustifolia*.
- 14(12). Lower leaf surface glabrous or scattered long-pilose 8. *V. urticifolia*.
14. Lower leaf surface uniformly and densely short-pubescent 8. *V. urticifolia* var. *leiocarpa*.
- 15(7). Leaf blades membranous, not conspicuously scabrous above, mostly glabrous or inconspicuously strigillose beneath 9. *V. hastata*.
15. Leaf blades rigid, harshly scabrous above, often conspicuously pubescent beneath .. 9. *V. hastata* var. *scabra*.
- 16(5). Leaves predominantly entire, mostly linear, the lower ones sometimes with a few salient teeth 17. *V. perennis*.
16. Leaves not predominantly entire (17)
- 17(16). Leaves serrate-dentate or shallowly incised (18)
17. Leaves deeply incised-dentate to pinnatifid or 3-cleft (20)

- 18(17). Plants coarse, more or less densely hirsute-pubescent or hirsute-villous; leaves elongate-elliptic to ovate-orbicular; spikes stout, 7-10 mm. wide during anthesis (19)
18. Plants slender, densely canescent-hirtellous with short hairs; leaves linear to narrowly-elliptic; spikes more slender, 5-6 mm. wide during anthesis 16. *V. neomexicana* var. *hirtella*.
- 19(18). Leaves elongate-elliptic to ovate-acuminate, short-petiolate; corolla limb 5-6 mm. wide 11. *V. Macdougalii*.
19. Leaves ovate-orbicular, sessile; corolla limb 8-9 mm. wide 10. *V. stricta*.
- 20(17). Spikes not conspicuously bracteose; bractlets not foliaceous (21)
20. Spikes conspicuously bracteose with somewhat foliaceous bractlets (at least at the base of the spike) (31)
- 21(20). Leaf blades (at least the lower ones) oblong-ovate or obtusely elliptic-ovate, not narrowly elongate, usually 3-cleft with the segments incised-dentate (22)
21. Leaf blades (at least the lower ones) oblong-lanceolate to spatulate, narrowly elongate, usually incised-pinnatifid or incised-dentate (27)
- 22(21). Leaves petiolate; pubescence various but not coarsely hirsute; spikes often stout, not greatly elongate if slender (23)
22. Leaves subsessile or at most very shortly petiolate; pubescence coarsely hirsute or glandular; spikes slender and greatly elongate (25)
- 23(22). Corolla tube scarcely longer than the calyx, 4-4.5 mm. long; corolla limb 4-6 mm. wide 14. *V. plicata*.
23. Corolla tube far-exceeding the calyx, 8 mm. or more long; corolla limb 7-8 mm. wide (24)
- 24(23). Corolla blue to lavender or purple 15. *V. Cloverae*.
24. Corolla white 15. *V. Cloverae* f. *alba*.
- 25(22). Pubescence on calyx long, whitish, appressed, not glandular 12. *V. xutha*.
25. Pubescence on calyx shorter, sordid, spreading, glandular (26)
- 26(25). Corolla mostly blue 13. *V. Runyonii*.
26. Corolla mostly rose 13. *V. Runyonii* f. *rosiflora*.
- 27(21). Plants coarse, with a low somewhat compact habit, canescent-hirsute; leaves subpinnatifid, contracted into a broadly margined semiamplexicaul or petiolar base (28)
27. Plants more slender, with a taller and open habit, hirsute or canescent-hirtellous; leaves pinnately cleft to incised-dentate, with a narrowly margined petiolar base (29)
- 28(27). Inflorescence somewhat glandular-hirsute; bractlets lanceolate 18. *V. canescens*.
28. Inflorescence sparsely or not glandular, densely hirsute; bractlets ovate, sharply acuminate 18. *V. canescens* var. *Roemeriana*.
- 29(27). Corolla limb 4 mm. wide; commissural faces extending to the tip of the cocci; pubescence hirsute, sparse on the stems 16. *V. neomexicana*.
29. Corolla limb 6-10 mm. wide; commissural faces scarcely extending to the tip of the cocci (30)
- 30(29). Plants more or less hirsute; leaves pinnately cleft; bractlets lanceolate 16. *V. neomexicana* var. *xylopoda*.
30. Plants canescent-hirtellous; leaves dentate or somewhat more deeply incised; bractlets ovate 16. *V. neomexicana* var. *hirtella*.

- 31(20). Leaves more or less strongly plicate; venation noticeably whitish near the margins (32)
31. Leaves not plicate nor conspicuously whitish-veined near the margins (35)
- 32(31). Corolla tube scarcely longer than the calyx, 4-4.5 mm. long; corolla limb 4-6 mm. wide (33)
32. Corolla tube far-surpassing the calyx, 8 mm. or more long; corolla limb 7-8 mm. wide (34)
- 33(32). Bractlets ovate-lanceolate, green, herbaceous, gradually attenuate from base to apex 14. *V. plicata*.
33. Bractlets broadly ovate, dry, rigid, very abruptly acuminate at apex 14. *V. plicata* var. *Degereri*.
- 34(32). Corolla blue to lavender or purple 15. *V. Cloverae*.
34. Corolla white 15. *V. Cloverae* f. *alba*.
- 35(31). Leaves with a subpetiolar or semiamplexicaul base; bractlets ovate, a little longer than the flowers, abruptly acuminate, ascending 18. *V. canescens* var. *Roemeriana*.
35. Leaves narrowed into a margined petiole; bractlets linear-lanceolate, much longer than the flowers, usually reflexed in age 19. *V. bracteata*.
- 36(1). Cocci with a very definite beak parallel to the axis of the schizocarp 21. *V. quadrangulata*.
36. Cocci with an indefinite beak or beakless (37)
- 37(36). Cocci suggesting a tendency toward a beak (a slight protrusion horizontal to the axis of the schizocarp); commissural face practically reaching to the tip of the coccus (38)
37. Cocci without a beak or tendency toward one; commissural face not reaching the tip of the coccus (39)
- 38(37). Corolla in shades of pink 22. *V. delticola*.
38. Corolla lavender 22. *V. delticola* f. *lilacina*.
- 39(37). Cocci subovoid, the lateral surfaces ventricose and smooth, not at all similar to the dorsal surface 26. *V. tumidula*.
39. Cocci subcylindric, the lateral surfaces not ventricose, usually scrobiculate, similar to the dorsal surface (40)
- 40(39). Leaves shallowly lobed to incised or toothed (41)
40. Leaves 3-cleft to incised-pinnatifid or bipinnatifid (45)
- 41(40). Flowers very large and showy; corolla 20-30 mm. long, its limb 10-24 mm. wide (42)
41. Flowers small and inconspicuous; corolla 7-10 mm. long, its limb 2-7 mm. wide 20. *V. cameronensis*.
- 42(41). Leaves appressed-strigose or glabrate (43)
42. Leaves rather densely pubescent (44)
- 43(42). Corolla blue to pink or purple 23. *V. canadensis*.
43. Corolla white 23. *V. canadensis* f. *candidissima*.
- 44(42). Corolla to 2 cm. long and 12 mm. wide 24. *V. elegans* var. *asperata*.
44. Corolla to 3 cm. long and 24 mm. wide 25. *V. hybrida*.
- 45(40). Corolla tube protruding well beyond the calyx (46)
45. Corolla tube only slightly longer than the calyx (61)
- 46(45). Corolla tube approximately twice as long as the calyx (47)
46. Corolla tube one and one third to one and one half times as long as the calyx (48)

- 47(46). Bractlets usually one half to two thirds as long as the calyx; inflorescence usually not greatly elongating 24. *V. elegans* var. *asperata*.
47. Bractlets usually subequaling or only slightly shorter than the calyx; inflorescence conspicuously elongating 23. *V. canadensis*.
- 48(46). Floral bractlets equaling or exceeding the calyx; calyx hispid-hirsute, not glandular (49)
48. Floral bractlets shorter than the calyx; calyx hispid-hirsute to villous-pubescent and mostly somewhat glandular or appressed-strigose and not glandular (52)
- 49(48). Leaves bipinnatifid, the ultimate segments linear-oblong (50)
49. Leaves not bipinnatifid, usually more or less 3-cleft, with the segments remotely incised or lobed, the ultimate segments much broader than in the above (51)
- 50(49). Calyx and bractlets hispid-hirsute 27. *V. bipinnatifida*.
50. Calyx and bractlets finely appressed-pubescent or puberulent
..... 28. *V. oklahomensis*.
- 51(49). Sinuses of leaves extending practically to the midrib, the segments sharply acute at the apex; western 27. *V. bipinnatifida* var.
latilobata.
51. Sinuses of leaves usually rather shallow, the segments obtuse at the apex; Rio Grande Plains and Valley 22. *V. delticola*.
- 52(48). Calyx appressed-strigose with sericeous hairs, not glandular; introduced (53)
52. Calyx hispid-hirsute or villous, mostly more or less glandular; native (54)
- 53(52). Corolla blue to purple or rose 29. *V. tenuisecta*.
53. Corolla white 29. *V. tenuisecta* var. *alba*.
- 54(52). Plants coarse; leaves usually 2.5-4 cm. long, hispidulous-hirsute; corolla limb 6-12 mm. wide; cocci 2.5-3 mm. long; corollas mostly blue, pink or purple (55)
54. Plants slender; leaves smaller, 1-2.5 cm. long, hirtellous; corolla limb 5-6 mm. wide; cocci 2 mm. long; corollas always white 33. *V. racemosa*.
- 55(54). Calyx teeth 2-3 mm. long (56)
55. Calyx teeth usually less than 2 mm. long (58)
- 56(55). Plants usually tall (2-4 dm.); leaves bipinnatifid, with the ultimate segments lanceolate; calyx teeth not especially conspicuous in mature fruit (57)
56. Plants usually low (1-2 dm.); leaves trifid, with the segments more or less incised; calyx teeth conspicuously long in mature fruit 32. *V. ciliata* var.
longidentata.
- 57(56). Calyx glandular 30. *V. ambrosifolia*.
57. Calyx not glandular 30. *V. ambrosifolia* f.
eglandulosa.
- 58(55). Plants decumbent-ascending or prostrate, densely hirsute; calyx somewhat glandular, hispidulous-hirsute, scarcely viscid (59)
58. Plants ascending-erect, more or less hirsute; calyx densely glandular-hirsute and somewhat viscid-pubescent (60)
- 59(58). Plants with decumbent-ascending loose habit; leaf margins slightly revolute ..
..... 32. *V. ciliata*.
59. Plants with prostrate compact habit; leaf margins strongly revolute
..... 32. *V. ciliata* var. *pubera*.
- 60(58). Corolla pink to purple 31. *V. Wrightii*.
60. Corolla white 31. *V. Wrightii* f. *albiflora*.
- 61(45). Corolla inconspicuous, its limb 3-5 mm. wide; plants decumbent, more or less hirsute (62)
61. Corolla conspicuous, its limb 8-9 mm. wide; plants erect or ascending, densely white-villous 34. *V. Gooddingii*.

- 62(61). Corolla blue to pink or lavender35. *V. pumila*.
 62. Corolla white35. *V. pumila* f. *albida*.

1. *Verbena rigida* Spreng. TUBER VERVAIN. Stems 2-6 dm. tall, scabrous; leaves sessile, oblong to oblong-lanceolate or narrowly obovate, subcordate and semiamplexicaul at base, coarsely sharp-serrate, scabrous on both surfaces, revolute-margined when old; spikes usually short, dense, cylindrical, in subternate cymes, the laterals pedunculate; bractlets lanceolate, acuminate-subulate, usually closely imbricate and longer than the calyx, glandular-pubescent, ciliate; calyx 4 mm. long, glandular-pubescent, the acute lobes with short mucronulate-subulate tips; corolla mostly purple to magenta, the tube 2 or 3 times as long as the calyx, pubescent outside, limb 5-7 mm. wide. *V. venosa* Gill. & Hook. Pastures, prairies and roadsides, adv. from cult., very showy in large patches, e. Tex. w. to Fayette and Travis cos., Apr.-Oct.; nat. to Braz. and Parag., introd. in W.I. and s. U.S.

2. *Verbena bonariensis* L. SOUTH AMERICAN VERVAIN. Stiffly erect, 1 m. or more tall, somewhat scabrous-pubescent; leaves sessile, subcordate and semiamplexicaul at base, lanceolate or oblong, sharply serrate, rugose and hirtellous above, spreading-pubescent beneath; spikes compact, mostly short, usually sessile and crowded in dense fasciculate cymes, not elongating; bractlets lanceolate-acuminate, barely equaling or slightly surpassing the calyx, pubescent; calyx 3 mm. long, pubescent, the acute lobes with short subulate tips; corolla blue to violet or purple, the tube scarcely twice as long as the calyx, pubescent outside, limb inconspicuous. Sandy loam, moist flatlands and along rice field fences, introd. in e. Tex. from Red River to Jefferson cos., Apr.-June; nat. of Braz., Parag., Urug. and Arg.; introd. in W.I., s. U.S. and elsewhere.

3. *Verbena litoralis* H.B.K. SEASHORE VERVAIN. Fastigiate branched, to 1 m. tall, glabrous or sparsely strigillose; leaves lanceolate or oblong, 3-10 cm. long, tapering into a very short petiole or subsessile, more or less sharply and coarsely serrate, sparsely strigillose on both surfaces, often slightly scabrous and rugose above; spikes terminal, pedunculate, cymosely arranged or paniculate, at first fairly dense, usually soon elongating; bractlets ovate-lanceolate, subequaling or somewhat shorter than the calyx, not conspicuous, acuminate, glabrate; calyx 2-2.5 mm. long, finely strigillose, subtruncate, the subulate teeth minute; corolla blue to lavender or purple, the tube longer than the calyx limb, 2.5-3 mm. wide, inconspicuous. Waste ground, introd. in Newton Co.; nat. from Mex. almost throughout C.A. and S.A.; introd. in H.I., Calif., La. and elsewhere.

4. *Verbena brasiliensis* Vell. BRAZILIAN VERVAIN. Stems stout, to 25 dm. tall, acutely tetragonal, practically glabrous below, somewhat scabrous-pubescent above, slightly contracted at nodes; leaves elliptic or lanceolate, tapering into a cuneate subsessile or petiolar base, sharply serrate or incised (at least above the middle), strigillose and somewhat pustulate above with impressed venation, sparsely pubescent beneath; spike compact, mostly short, not much elongating, usually sessile in open cymes, numerous but not crowded; bractlets scarcely as long as the calyx, lanceolate-subulate, ciliate; calyx 2.5-3.5 mm. long or more, somewhat appressed-pubescent, the acute lobes with short subulate tips; corolla purple or lilac, the tube a little longer than the calyx, pubescent outside, the limb 2.5 mm. wide, inconspicuous. Waste places, dry sandy soil, coastal prairies, mainly in s.e. Tex., May-Oct., introd.; nat. to most of S.A.; naturalized from Va. to Fla. and Gulf Coast, Ore., Calif., Jam., S. Afr. and elsewhere.

5. *Verbena menthaefolia* Benth. MINT VERVAIN. Stems decumbent or ascending, branched, sparsely and minutely hispidulous; leaves ovate, 3-6 cm. long, tapering at base into a margined petiole, deeply cleft or subincised, the divisions remotely serrate-dentate, strigillose on both surfaces, somewhat pustulate above; spikes paniced, slender, elongate, compact only at the apex; bractlets ovate-lanceolate, acuminate, usually shorter than the calyx, sparsely strigillose, ciliate; calyx 2.5-3 cm. long, strigillose, sparsely or not glandular, the teeth minute; corolla blue or light purple, the tube only slightly longer than the calyx, limb about 6 mm. wide, lobes more or less truncate. Bottomlands, ravines, stream-sides and roadsides, Uvalde and Bexar cos.; also in Ariz., s. Calif. and most of Mex. Misidentified as *V. officinalis* L. in some works.

6. *Verbena Halei* Small. TEXAS VERVAIN. Stems usually several from a woody base, erect, ascendingly branched, glabrous or strigillose above; leaves 3-10 cm. long, strigillose on both surfaces, diverse in shape, the basal and lower stem leaves oblong to ovate, tapering into a petiole about as long as the blade, irregularly dentate or incised, middle

stem leaves 1- or 2-pinnatifid with shorter petioles, uppermost leaves sparingly dentate or entire; spikes paniculate, slender, elongate; bractlets about half as long as the calyx, appressed, ciliate; calyx 3-3.5 mm. long, strigillose, subtruncate, unequal teeth subulate; corolla mostly blue, the tube scarcely longer than the calyx, the limb 6-7 mm. wide, lobes retuse. Sandy or calcareous meadows, prairies, fields, woodlands, rocky hillsides and roadsides, often very abundant, widespread practically throughout Tex., especially in e., cen. and s. sections, Feb.-Nov.; Ala. to Okla. and Tam. Widely misidentified as *Eur. V. officinalis* L. in older works.—*f. albiflora* L. I. Davis has white corollas; known from Brooks and Hidalgo cos.; *f. roseiflora* (Benke) Moldenke has deep-rose or pink corollas, known from Goliad, Hood and Kleberg cos.

7. *Verbena scabra* Vahl. SANDPAPER VERVAIN. Stems to 1 m. tall, erect, solitary, simple or branched, hispidulous; leaves ovate, 3-13 cm. long, to 5 cm. wide, petiolate, acute or obtusish, serrate-dentate, very rough and usually strigillose above, less scabrous and paler beneath, hispidulous on the venation; spikes paniculate, slender, pedunculate, closely many-flowered; bractlets ovate-acuminate, half as long as the calyx, hispidulous; calyx 2.5-3 mm. long, ovoid, hispidulous, diverging from the rachis by 45° or more, the unequal lobes acutely connivent; corolla blue, the tube about equaling the calyx, limb 2 mm. wide, lobes obtuse; stigmatic surface midway between 2 almost equal obtusish sterile style lobes. Mostly rich soil of low ground, marshes, swamps and edges of lakes and streams, throughout most of Tex. except Plains Country; Mar.-Dec.; N.C. to Fla. and W. I., w. to Ariz., Calif. and n. Mex.—*f. angustifolia* Moldenke differs in having elliptic to elliptic-lanceolate leaves only to 2 cm. wide; known only from Burnet Co.

8. *Verbena urticifolia* L. WHITE VERVAIN. Stems solitary, to 25 dm. tall, coarse, simple or branching from near the base, hispid or hirtellous to almost glabrous; leaves petiolate, broadly lanceolate to oblong-ovate, 8-20 cm. long, acute or shortly acuminate, coarsely crenate-serrate, rounded at base and decurrent into the petiole, glabrous on both surfaces or scattered-pilose with rather long irregular hairs beneath; spikes paniculate, slender, pedunculate, rather sparsely flowered, often very elongate; bractlets ovate-acuminate, very short, ciliate; calyx 2 mm. long, pubescent (especially on the veins), the obtuse lobes not connivent, the short and subequal teeth subulate; corolla white, very small, the tube scarcely surpassing the calyx, limb 2 mm. wide, lobes obtuse. Low rich or open woods, bottomlands, waste places, fencerows, pastures and streamsides, from Bowie and Wilbarger to Newton, Brazoria and Gonzales cos., also in Wheeler Co. in the Panhandle, June-Oct.; Que. and Ont. to Neb., s. to Fla. and w. to Tex. and Okla.—*var. leiocarpa* Perry & Fern. differs in having the lower leaf surface uniformly and densely short-pubescent; known from Cass Co.; it occurs sporadically almost throughout the extralimital range of the species.

9. *Verbena hastata* L. BLUE VERVAIN. Stems to 23 dm. tall, mostly simple, stiffly erect, often branched above, mostly rough-pubescent with short antrorse hairs; leaves lanceolate or oblong-lanceolate, occasionally ovate-lanceolate, petiolate, 5-18 cm. long, gradually acuminate, coarsely serrate or incised, sometimes hastately 3-lobed at base, glabrous or slightly pubescent, not scabrous; spikes usually numerous, paniculate, stiffly erect, pedunculate, compact, densely many-flowered; bractlets lanceolate-subulate, usually a little shorter than the calyx; calyx 2.5-3 mm. long, pubescent, the acute lobes with short subulate tips and more or less connivent; corolla purplish-blue, the tube somewhat longer than the calyx, pubescent outside, the limb 3-4.5 mm. wide. Moist fields, meadows, prairies, swamps, woods and streamsides, Plains Country, July-Oct.; N.S. to B.C., s. to Fla., Neb. and Ariz. In dry fields and pastures a field-form is developed with the leaves more canescent-puberulous beneath and slightly rough above, the stem many-branched, and the terminal inflorescences in many groups, all more or less equally dense.—*var. scabra* Moldenke differs in its more rigid leaves that are conspicuously scabrous above and often more or less conspicuously pubescent beneath; known from Hemphill Co.; a w. form of the species, B.C., Ida., Mont. and N.D. to Calif., N.M. and Tex., e. to Wisc. and Kan.

10. *Verbena stricta* Vent. HOARY VERVAIN. Stems to 2 m. tall, subterete, simple or branched above, often very robust, rather densely hirsute, often canescent; leaves ovate or oblong to elliptic or suborbicular, sessile or nearly so, sharply serrate or biserrate to irregularly incised-serrate, thick-textured, hirsute and rugose above, densely hirsute-villous and prominently veined beneath, often canescent; spikes solitary or several, short-

pedunculate, thick, usually quite dense both in anthesis and in fruit, often more than 3 dm. long; bractlets lanceolate-subulate, about as long as the calyx, hirsute, ciliate; calyx 4-5 mm. long, densely hirsute, the lobes acuminate; corolla blue or purple, the tube slightly surpassing the calyx, pubescent outside, limb 8-9 mm. wide. Pastures, prairies, waste places and railroad embankments, usually in dry soil, from Lipscomb to Red River, Liberty and Gonzales cos., June-Sept.; Ont. and O., w. to S.D. and Wyo., s. to Tex. and N.M.; introd. in e. U.S. and in Wash.

11. *Verbena Macdougali* Heller. NEW MEXICAN VERVAIN. Stems to 1 m. tall, stout, obtusely tetragonal, simple or occasionally branched, ashy-green, hirsute-pubescent; leaves oblong-elliptic or elongate-ovate, 6-10 cm. long, short-petiolate or narrowed into a subpetiolar base, coarsely and irregularly serrate-dentate, hirtellous, rugose and minutely pustulate above, densely pilose-pubescent and prominently veined beneath; spikes solitary or sometimes several, thick, comparatively dense both in anthesis and in fruit; bractlets lanceolate-subulate, usually longer than the calyx, pubescent, ciliate; calyx 4-5 mm. long, rather densely pubescent, the very obtuse lobes ending in short subulate teeth; corolla deep-purple, the tube scarcely surpassing the calyx, the limb 6 mm. wide. On flats at high elev., Culberson Co., June-Oct.; also s. Wyo. and cen. Ut. to N.M. and Ariz.

12. *Verbena xutha* Lehm. GULF VERVAIN. Stems usually upright, to 2 m. tall, coarse and spindly, tetragonal, often tufted in clumps from a common base, branched, hirsute-hispid, rarely procumbent; leaves oblong or broadly ovate in outline, sessile, 5-12 cm. long, incised-pinnatifid or more often trifid, with the segments coarsely dentate, the laterals much smaller than the middle segment and close to the leaf base, strigose above, canescent and spreading-hirsute beneath, the hairs especially conspicuous along the somewhat paler venation, the upper leaves lanceolate; spikes elongate, rather stiff, compact only during anthesis, short-pedunculate; bractlets lanceolate-subulate, subequaling or a little shorter than the calyx, strigillose, ciliate; calyx 3-4 mm. long, strigose-hirsute, the lobes acuminate-subulate; corolla blue to purple, the tube about as long as the calyx, pubescent outside, throat white, villous, limb 5-8 mm. wide. *V. Matthesii* Turcz. Dry mostly sandy soil of beaches, fields, roadsides and blackland prairies, Bowie and Navarro to Jefferson and Cameron cos., w. to the Trans-Pecos, Mar.-Oct.; Ala. to Ariz.

13. *Verbena Runyonii* Moldenke. RIO GRANDE VERVAIN. Stems erect, coarse, to 14 dm. tall, green, rather stout, sharply tetragonal, sparsely hirsutulous with short whitish divergent hairs especially on the angles and at the nodes, glabrescent in age but more or less scabrellous on the angles; leaves sessile, clasping, 2-6 cm. long, 8-30 mm. wide, more or less 3-parted with each division pinnatifid-incised with broad acute teeth, abundantly hirsutulous on both surfaces with rather short whitish hairs that are bulbous-based, the upper surface scabrous on older leaves; spikes compound, the branches slender, erect, 14-25 cm. long, rather closely many-flowered, often with 1 to 3 pairs of much reduced leaves near the base; flowers with a faint odor, very densely imbricate before and during anthesis, rather uniformly separated in fruit; peduncles and rachis slender, sharply tetragonal, spreading-pilose and glandular, the hairs very short; bractlets linear-lanceolate, 3 mm. long, equaling the calyx, sharply attenuate, rather sparsely puberulent and glandular, sparsely and irregularly ciliolate toward the base; calyx 3 mm. long, glandular-pilose with short spreading hairs; corolla blue, 6 mm. long, tube puberulent at apex outside, limb 4 mm. wide. Mostly in moist ground, open fields, banks, resaca bottoms, ditches and roadsides, from Hidalgo and Cameron cos. along the coast to Nueces Co., Feb.-June; also N.L.; introduced in Ore.-f. *rosiflora* L. I. Davis differs in having rose-colored corollas; known only from Cameron Co.

14. *Verbena plicata* Greene. FANLEAF VERVAIN. Stems decumbent or ascending, branched, hirtellous; lower leaf blades elliptic-ovate, 1-4 cm. long, narrowed at base into a margined petiole of about the same length, broadly obtuse at apex, plicate, coarsely incised-dentate, often 3-lobed, more or less canescent, rugose and somewhat appressed-hirsute above, hirsute beneath and prominently marked (especially near the margins) with whitish veins; upper leaves similar but smaller, often subspatulate; spikes terminal on stems and branches, usually not compact; bractlets green, herbaceous, ovate-lanceolate, equaling or usually surpassing the calyx, 5-7 mm. long, 1.5-4 mm. wide, gradually attenuate from base to acute apex, hirsute, the midrib often conspicuous; calyx 3.5-4 mm. long, glandular-hirsute, the very obtuse or subtruncate lobes terminating abruptly in

subulate teeth; corolla blue to lavender or purple, the tube subequalling the calyx, limb 4-6 mm. wide, anterior lobe obtuse. Open sandy ground, flats, prairies, ravines, cliffs, gravel hills and roadsides, from Childress and Young to Gonzales and Cameron cos. w. to the Trans-Pecos, Feb.-Sept.; also N.M., Ariz. and n. Mex.—var. *Degeneri* Moldenke differs in the bractlets being very firm and rigid, dry, stramineous, broadly ovate, to 9 mm. long and 6 mm. wide, and very abruptly long-acuminate; known only from Brewster and Pecos cos.

15. *Verbena Cloverae* Moldenke. CLOVER'S VERVAIN. Branching from near the woody base; branches rather sharply 4- or 5-angled, densely short-villous, the hairs at right angles to the branches, not glandular; petioles 5-15 mm. long, broadly winged to the base; leaf blades rather firm, resembling those of *V. plicata*, mostly ovate, 1.5-3 cm. long, 1-2.5 cm. wide, coarsely and irregularly incised-dentate or shallowly 3-lobed toward the base, obscurely short-puberulent above, more densely short-pubescent (especially on the larger venation) beneath; the entire venation impressed above and very prominent and whitish beneath as in *V. plicata*; leaves in the inflorescence small, sessile to shortly winged-petiolate, sharply and coarsely incised-dentate or lobed, firm and rather stiff, rapidly decreasing in size upwards; spikes 8-25 cm. long; bractlets lanceolate, stiff, the lowermost to 7 mm. long, the uppermost 2.5-3 mm. long, shorter than the calyx in anthesis; calyx 4-4.5 mm. long, prominently 4-ribbed, the ribs hirsute, purplish as in *Stylodon carneus* before and during anthesis; corolla bluish to pink, lavender or purple, its tube far-surpassing the calyx, 8 mm. long or more, limb 7-8 mm. wide. Open slopes, in clay and sandy soil, and open desert scrub, from Coke and Houston cos. s. to Kenedy and Hidalgo cos., Feb.-May; endemic.—f. *alba* Lundell differs in having white corollas; known only from Dimmit and Zapata cos.—var. *lilacina* Moldenke, described as having lavender corollas, appears to be only a transitory state in flower maturity.

16. *Verbena neomexicana* (Gray) Small. HILLSIDE VERVAIN. Stems slender, erect, to 1 m. tall, branched from the base, hirsute; leaves 1-5 cm. long, pinnately cleft or almost parted, the segments incised or coarsely toothed, rugose, somewhat scabrous and finely pustulate above, the venation rather prominent beneath, hirsute on both surfaces; spikes solitary or paniced, mostly short-pedunculate, hirsute; bractlets lanceolate-acuminate, mostly not surpassing the calyx; calyx 3 mm. long, hirsute-pubescent, very slightly glandular, the teeth short and subulate; corolla blue to lavender or purple, the tube scarcely surpassing the calyx, limb 4 mm. wide. Pine-oak forests, streambeds, gravel and sand bars, streamsides and rocky hillsides, from Travis and Cameron cos. w. to the Trans-Pecos, Apr.-Nov.; also N.M. and n. Mex.—var. *xylopoda* Perry differs in having shorter, denser, and more glandular pubescence, the glandular-hirsute calyx 4 mm. long and with acuminate teeth, and the corolla limb 6-10 mm. wide; sandy soil on hillsides, Rio Grande Plains; also s. Calif., Ariz. and n. Mex.; introd. in Fla.—var. *hirtella* Perry differs in being densely canescent-hirtellous, the leaves only rather shallowly incised, the bractlets usually broadly ovate-acuminate, and the corolla limb 8 mm. wide; dry arroyos and desert scrub, plains and foothills, from Trans-Pecos Tex. e. to Travis and Cameron cos.; also N.M., Ariz. and n. Mex.; introd. in Md.

17. *Verbena perennis* Woot. PINLEAF VERVAIN. Stems 3-4 dm. tall, several from a woody base, divaricately ascending or erect, usually somewhat branched, glabrate or often finely glandular and slightly short-hispidulous; leaves mostly linear, 1-4 cm. long, mostly entire or the lowest pinnately few-lobed, erect-ascending, sparsely hispidulous, revolute-margined; spikes terminal, pedunculate, filiform, elongate; bractlets ovate, 1.5-3 mm. long, acute, hispidulous, ciliate; calyx 4-5 mm. long, more abundantly pubescent on the veins, the subequal lobes short and acute; corolla deep-blue to lavender or purple, the tube slightly longer than the calyx, pubescent, limb 5-7 mm. wide, lobes repand. Rough grassy slopes, hillsides and flats, in the Trans-Pecos, Mar.-Nov.; also N.M., Ariz. and Coah.

18. *Verbena canescens* H.B.K. GRAY VERVAIN. Stems several, branched, tetragonal, decumbent to ascending or erect, canescent, hirsute, 15-46 cm. tall; leaves oblong-lanceolate, rigid, mostly sessile, 1-5 cm. long, acute, remotely incised-dentate or sub-pinnatifid, semiamplexicaul at base, rugose and hirtellous above, canescent-hirsute and often rather conspicuously veined beneath; spikes sessile or short-pedunculate, mostly solitary, loose-flowered or compact, glandular-hirsute; bractlets lanceolate, acuminate, variable in length, often surpassing the calyx, hirsute, ciliate; calyx 2-3 mm. long,

canescent-hirtous, somewhat glandular, subtruncate, the teeth short and very inconspicuous; corolla blue to lavender or purple, the tube slightly surpassing the calyx, limb 4-6 mm. wide, lobes retuse. In sand and rocky places on dry limestone hills, valleys and canyons, Edwards Plateau and s.-cen. Tex., Apr.-Oct.; widespread in Mex.; introd. in Nev.—var. *Roemcristana* (Scheele) Perry differs in being more densely hirsute, sparsely or not at all glandular, and the bractlets broadly ovate, abruptly acuminate, concave during anthesis, later slightly recurved, and mostly surpassing the calyx. Dry rocky or sandy soil, clay slopes and hillsides, ravines, open woodlands, cedar brakes, fields, pastures and blackland prairies, preferring dry rocky hillsides, from the Trans-Pecos s. to Cameron Co., e. to Wharton and Waller cos., n. to Wichita and Scurry cos., Mar.-Oct.; also s. Calif. and n. Mex.

19. *Verbena bracteata* Lag. & Rodr. PROSTRATE VERVAIN. Stems usually several from a common base, diffusely branched, prostrate or decumbent, rarely erect, coarsely hirsute; leaves 1-6 cm. long, pinnately incised or 3-lobed (lateral lobes narrow and divaricate, middle lobe large, cuneate-obovate, incised-dentate or cleft), narrowed into a short margined petiole, hirsute on both surfaces, larger venation slightly prominent beneath; spikes terminal, sessile, ascending, rather thick, conspicuously bracteose; bractlets much longer than the calyx, spreading-ascending, recurved in age, coarsely hirsute, foliaceous, the lowermost often incised, the upper linear-lanceolate, acute to acuminate and entire; calyx 3-4 mm. long, hirsute especially on the veins, the very short lobes connivent; corolla bluish to lavender or purple, the tube slightly surpassing the calyx, very finely pubescent outside, the limb 2.5-3 mm. wide. *V. bracteosa* Michx. Low and newly cleared ground, grassy places, waste ground and roadsides, from the Trans-Pecos and Plains Country through the Edwards Plateau e. to Newton Co., Apr.-Oct.; almost throughout the U.S. and s. Can., introd. and local eastw.

20. *Verbena cameronensis* L. I. Davis. SOUTHWEST VERVAIN. Stems slender, decumbent or ascending, obtusely tetragonal, abundantly hirsute with stiff white hairs; branches numerous, very slender, ascending or erect, more densely hirsutulous; petioles 5-25 mm. long, slightly margined, densely hirsutulous; leaf blades thin, ovate, to 7 cm. long and 53 mm. wide, acute, subtruncate at base and slightly prolonged into the petiole, coarsely and irregularly incised-dentate with blunt or subacute teeth, scattered appressed-pilose on both surfaces with whitish hairs; spikes abbreviated, 2-6 cm. long during anthesis, densely many-flowered, the flowers closely imbricate before and during anthesis, somewhat more separated in fruit, elongated to 15 cm. in fruit, densely hirsutulous, often glandular; bractlets linear-lanceolate, 6 mm. long, slightly shorter or longer than the calyx, densely puberulent, long-ciliate; calyx tubular, swollen, 5-6 mm. long, somewhat puberulent and sparsely white-hirsutulous, not glandular; corolla small, inconspicuous, lavender to purple, the tube barely surpassing the calyx, 7-11 mm. long, limb 2-8 mm. wide. *V. Lundelliorum* Moldenke. Woodlands, fields, clearings and roadsides, Cameron Co., Apr.-May; also n. Mex. s. to Ver. and S.L.P.

21. *Verbena quadrangulata* Heller. BEAKED VERVAIN. Stems prostrate-ascending, diffusely branched from the base, rooting at the lower nodes, hirsute; leaves 1-3 cm. long, broadly ovate, cuneate at base and contracted into a very short margined petiole, incised-pinnatifid or 3-cleft, the lobes again incised, strigose-hirsute on both surfaces; spikes compact, sessile or nearly so, terminal; bractlets narrowly lanceolate, somewhat shorter than the calyx, hirsute, ciliate; calyx 5-6 mm. long, hirsute especially on the ribs, the short lobes subulate-tipped; corolla mostly white, varying to bluish, pink or lavender, the tube slightly surpassing the calyx, subglabrous outside, the limb 2.5-3 mm. wide, lobes emarginate; anthers unappendaged; ovary surmounted by a subhemispheric-angulate stylopodium; each coccus surmounted by a smooth obtusish beak. *Helleranthus quadrangulatus* (Heller) Small. Waste and open grounds, fields, desert scrub, clay slopes, caliche and sandy beaches, from Pecos and Upton to Cameron and Wharton cos. n. to Tarrant Co., Feb.-Aug.; also Tam.

22. *Verbena delticola* Perry. ALFOMBRILLA, MORADIA. Stems decumbent to ascending, to 3 dm. tall, branched, more or less hirsute; leaves ovate-deltoid, 3-7 cm. long, obtuse or subacute, the truncate-cuneate base narrowed into a margined petiole, coarsely serrate-dentate, often 3-lobed, usually thin-textured, sparsely appressed-hirsute on both surfaces; spikes pedunculate, fasciclelike during anthesis, elongating in fruit; bractlets linear-attenuate, shorter than or equaling the calyx; calyx 7-8 mm. long, hirsute, sparsely glandu-

lar, the slender lobes unequal and subulate; corolla showy, mostly red, pink or magenta, the tube 1-1.5 cm. long, protruding well beyond the calyx, pubescent or glabrate outside, the limb 7-10 mm. wide, lobes emarginate; cocci with a definitely broadened base and a slight protrusion suggesting a tendency toward a beak. Open grounds, fields, orchards and the edges of thickets, often covering acres of ground, Rio Grande Plains and Valley, Feb.-Aug.; also n. and e. Mex.—f. *lilacina* L. I. Davis differs in having lavender corollas: known only from Cameron Co.

23. *Verbena canadensis* (L.) Britt. ROSE VERVAIN. Stems decumbent or ascending, rooting at the lower nodes, branched, glabrate or rather irregularly spreading-hirsute; leaves thin-textured, very variable, ovate to ovate-oblong, 2.5-9 cm. long, 1.5-4 cm. wide, acute or acuminate, truncate or cuneate at base and narrowed into a margined petiole, incised or incised-pinnatifid to 3-cleft, appressed-hirsute or glabrate on both surfaces; spikes pedunculate, fasciclelike during anthesis, conspicuously elongating in fruit, densely many-flowered; bractlets linear-attenuate, shorter than or sometimes equaling the calyx, irregularly hirsute with weak hairs, ciliate; calyx 10-13 mm. long, weakly glandular-hirsute, the very slender lobes subulate-setaceous and unequal, the posterior lobe much shorter; corolla showy, mostly pink, rose or magenta, varying to blue, lavender or purple, sometimes variegated, the tube about twice as long as the calyx, glabrous to finely pubescent or glandular outside, the limb 11-15 mm. wide, lobes emarginate; anther glands usually present and large; cocci with a slightly broadened base. *Glandularia canadensis* (L.) Small. Extremely polymorphic; plants with white corollas are f. *candidissima* (Haage & Schmidt) Palm. & Steyerl., with dark-violet corollas are var. *atroviolacea* Dermen, with compact habit are var. *compacta* Dermen, with extra large corollas are var. *grandiflora* (Haage & Schmidt) Moldenke, with the leaf blades incised-pinnatifid or almost bipinnatifid and the calyx only 1 cm. or less in length are var. *Drummondii* (Lindl.) Baxt., and those with narrow pinnatifid lanceolate or ovate leaves, cuneate at base, and the calyx 12 mm. or more in length are var. *Lambertii* (Sims) Thell. Open ground, fields, woods, pinelands, roadsides and railroad embankments, often covering large areas of ground, mostly n.e., e. and s.e. Tex. but extending into n., cen., s. and w. cos. perhaps as introd.; Ill. to Tenn., s. Pa., Va., and Fla. w. to Colo.; introd. in Conn., N.Y., Mich. and Minn.

24. *Verbena elegans* H.B.K. var. *asperata* Perry. MOUNTAIN VERVAIN. Stems decumbent-ascending, branched, densely hirsute-hispid; leaves lanceolate-ovate, 2-5 cm. long, 1-3.5 cm. wide, cuneate at the base and narrowed into a margined petiole, variously incised-pinnatifid, trifid, cleft or lobed, somewhat appressed-hirsute on both surfaces, often with much-abbreviated branches or fascicles of smaller leaves in the axils; spikes terminal, pedunculate, dense, many-flowered, fasciclelike during anthesis, usually not elongating; bractlets usually one half to two thirds as long as the calyx, lanceolate, attenuate, glandular-hirsute, ciliate; calyx 8-10 mm. long, hispidulous-hirsute and glandular, the unequal teeth subulate with the larger about 2 mm. long, often the whole calyx or only the teeth purple; corolla pink or rose to purple, the tube 15-18 mm. long, sparsely pubescent outside, throat gibbous, limb 10-12 mm. wide. Limestone or sandstone outcrops in mts., canyons and arroyo margins, mt. meadows and forests; known only from Duval and Hidalgo cos.; widespread in Mex. at high alt.; often cult.

25. *Verbena hybrida* Voss. GARDEN VERBENA. Stems mostly procumbent or ascending, spreading or compact, rooting at the nodes, densely hirsute or villous; branches many, densely soft-villous with whitish hairs; petioles 2-7 mm. long, densely white-hirsute, margined; leaf blades thick, lanceolate or ovate, 1.3-7 cm. long, 1-4 cm. wide, acute, usually truncate or subtruncate at base or cuneately narrowed into the petiole, irregularly incised-dentate from apex to base with numerous acute and spreading often lobelike and doubly dentate teeth, densely soft-pubescent on both surfaces with whitish hairs, antrorsely strigose above and with hairs spreading from the larger venation beneath; spikes terminal, large and showy, pedunculate, densely white-hirsute, at first fasciclelike, later elongating, very densely many-flowered, the flowers closely imbricate; bractlets lanceolate, much shorter than the calyx, 5-6 mm. long, attenuate, densely white-pubescent; calyx 8-15 mm. long, 5-costate and -plicate, densely white-hirsutulous, the rim truncate and undulate to very shortly 5-apiculate; corolla very large and showy, white or variously colored, often with a white or yellow "eye", often very fragrant, the tube 1.5-3 cm. long, glabrous or obscurely pilosulous outside, limb 1-2.4 cm. wide. *V. hortensis* Vilm. Planted for ornament throughout the state and tending to escape in n.e., cen. and w. Tex., Mar.-Oct.; an artificial

hybrid of several S.A. speceis; there are hundreds of horticultural named varieties and forms.

26. *Verbena tumidula* Perry. PLAINS VERVAIN. Stems decumbent-ascending, 1.5-2 dm. long, branching, pilose-hirsute; leaves broadly ovate, 2-4 cm. long, cuneate at base and narrowed into the margined petiole, trifid with the segments again incised or coarsely crenate-dentate, appressed-pubescent or strigillose above, hirtellous beneath; spikes short-pedunculate, protruding slightly above the uppermost leaves, compact; bractlets ovate-lanceolate, not surpassing the calyx, acuminate, ciliate; calyx 8-9 mm. long, inflated at base, hirsute, finely glandular, the subulate teeth 1.5 mm. long; corolla blue-purple, the tube 11 mm. long, puberulent outside, limb 8-10 mm. wide; anthers not glandular. High Plains, Trans-Pecos and Edwards Plateau, May-Nov.; also N.M. and n. Mex.

27. *Verbena bipinnatifida* Nutt. DAKOTA VERVAIN, SMALL-FLOWERED VERBENA. Stems diffusely branched from the base, ascending, rooting at the lower nodes, densely hispid-hirsute; leaves petiolate, 2-6 cm. long, bipinnately parted or tripartite with the divisions again bipinnatifid, the lobes linear or oblong, appressed-hirsute on both surfaces, often revolute; spikes pedunculate, fasciclelike during anthesis, conspicuously elongating in fruit; bractlets mostly longer than the calyx, linear-subulate, hispid-hirsute, ciliate; calyx 8.5-10 mm. long, pubescent, hispid-hirsute on the veins, the very slender unequal lobes subulate-setaceous from a broader base; corolla very nectariferous, pink to lavender or purple, the tube one and one half times the length of the calyx, pubescent outside, limb 8-10 mm. wide, lobes emarginate. *Glandularia bipinnatifida* (Nutt.) Nutt. Dry plains and prairies, meadows, pastures, roadsides and streamsides, often covering large areas, widespread almost throughout the state except in most of the Trans-Pecos, throughout the year; S.D. to Mo. and Ala., w. to Colo. and Ariz.; also n. Mex. and in cult.—var. *latilobata* Perry differs in having its leaves trifid, with the segments remotely incised or lobed, strigillose above, hirtellous-hirsute (especially on the venation) beneath, the spikes compact or somewhat elongate in age, and the bractlets variable in length, usually equaling or surpassing the calyx; known from Brewster, Dallas and Hidalgo cos.; also in Okla., N.M., Ariz. and n. Mex.

28. *Verbena oklahomensis* Moldenke. Supposed natural hybrid between *V. canadensis* and *V. bipinnatifida*, with leaves deeply bipinnatifid and corollas small and densely pubescent outside as in *V. bipinnatifida*, but calyx and bractlets are finely appressed-pubescent or puberulent as in *V. canadensis*, only the lower bractlets conspicuously and densely ciliate at the base. Known from Lampasas Co.; also Ark. and Okla.

29. *Verbena tenuisecta* Briq. MOSS VERBENA. Stems decumbent, with divergent ascending branches, to 6 dm. tall, sparsely pilose with antrorse hairs, glabrescent in age; leaves triangular in outline, 2-3.5 cm. long, 2-3 cm. wide, tripartite-pinnatifid, the linear divisions 1-3 mm. long, entire or dentate, obtuse or sharply acute, revolute-margined, substrigose above with appressed antrorse hairs, more densely so along the venation beneath, glabrescent in age; spikes terminal, pedunculate, solitary, short and dense during anthesis, later elongating to 4 cm. or more; flowers sessile, at first dense and ascending, later loosely spreading; bractlets subovate-lanceolate, 2-3 mm. long, usually about one fourth the length of the calyx, canescent-puberulent; calyx 8-9 mm. long, densely white-strigose throughout with closely appressed antrorse hairs and a few scattered black glands, the tube about 7 mm. long, the teeth filiform-setulose; corolla blue to violet, lilac or purple, showy, the glabrous tube surpassing the calyx mouth by 3-5 mm., limb 10 mm. wide, lobes broadly obcordate, spreading, emarginate, ciliate-pilose at base; anthers with a scarcely exserted glandular appendage. "*V. pulchella* var. *gracilior* (Troncoso) Shinners," *Glandularia tenuisecta* (Briq.) Small. Roadsides, fields and waste places, from Sabine and Jefferson cos., s.w. to Zapata and Webb cos., Mar.-July; N.C. to Fla. and the Gulf Coast, with isolated colonies in Ill., Ky., Mo., Ariz. and Calif.; introd. from S.A.—var. *alba* Moldenke, differing in its white corollas; known from Angelina Co., to be expected throughout the range of the species.

30. *Verbena ambrosifolia* Rydb. WESTERN PINK VERVAIN, WESTERN PINK VERBENA, MORADILLA. Stems loosely decumbent-ascending, diffusely branched from the base, somewhat hirsute; leaves short-petiolate, 2-6 cm. long, bipinnatifid, the ultimate segments lanceolate, appressed-hirsute on both surfaces, slightly revolute-margined; spikes pedunculate or subsessile, fasciclelike in anthesis, somewhat elongate in fruit; bractlets a little shorter than the calyx, lanceolate-subulate, hirsute, ciliate; calyx 8-9 mm. long, glandular-

pubescent, hirsute especially on the veins, the elongate teeth subulate and often coarctate; corolla pink or rose to lavender or purple, the tube one and one third to one and one half times the length of the calyx, pubescent outside, limb 6-10 mm. wide. Fields, prairies, grassy and alkali flats, deserts, mesas and roadsides in the Trans-Pecos and Panhandle, Apr.-Dec.; also Colo., N.M., Ariz. and isolated colonies in S.D., Kan., Okla. and Ark.—*f. eglandulosa* Perry differs in its more hirsute-hispid pubescence on the flowers and the absence of glands; roadsides, open fields and waste ground, in sandy loam or black clay soil, often covering acres of ground, scattered from Childress, Young and Rockwell cos. s. to Cameron and Webb and w. to Culberson and El Paso cos., Feb.-Oct.; also Okla., N.M., Ariz. and n. Mex.

31. *Verbena Wrightii* Gray. DESERT VERBENA. Stems usually several from a common base, decumbent-ascending to erect, branched, sparsely hispid-hirsute, to 6 dm. tall; leaves subsessile or contracted into a short margined petiole, 2-4 cm. long, bipinnatifid or trifid, the divisions rather deeply incised, ultimate segments narrowly lanceolate, hirtellous or hirsute on both surfaces; spikes short-pedunculate, rather compact even in fruit; bractlets shorter than the calyx, lanceolate, acute or acuminate, hirsute-ciliate; calyx 7-9 mm. long, densely glandular-pubescent, hirsute on the veins, the unequal short lobes subulate and not coarctate; corolla pink or rose to magenta or purple, the tube 11-12 mm. long, pubescent around the throat, limb 6-8 mm. wide, lobes retuse. Fields, flats, dry gravelly creek beds and bars, dry or semidesert hillsides and slopes, in the Trans-Pecos e. to Ector, Bexar and Guadalupe cos., with an isolated colony in Montgomery Co., Feb.-Nov.; also Kan., Colo., Okla., N.M., Ariz. and n. Mex.—*f. albiflora* Moldenke, differing in its white corollas; known only from the Trans-Pecos.

32. *Verbena ciliata* Benth. MEXICAN VERVAIN, ALFOMBRILLA DEL CAMPO, MORADILLA. Stems several from a common base, annual, decumbent, branched, hispidulous-hirsute, rarely erect, to 6 dm. tall, canescent throughout; leaves short-petiolate or subsessile, sub-bipinnatifid or trifid, the divisions rather deeply incised, ultimate segments linear-oblong, slightly revolute-margined, hirsute-strigillose on both surfaces; spikes subsessile or short-pedunculate, rather compact even in fruit; bractlets a little shorter than the calyx, lanceolate, subulate-acuminate, hirsute, ciliate; calyx 7-8 mm. long, somewhat glandular, hirsute-hispidulous, the short lobes subulate and unequal; corolla showy, pink or red to violet or purple, the tube 10-12 mm. long, pubescent outside, limb 6-8 mm. wide, lobes retuse. Flats, plains and roadsides, growing in patches but not extensive areas like *V. bipinnatifida*, from the Trans-Pecos and Plains Country e. to Polk Co. and s. Cameron Co., Feb.-Nov.; also Okla., N.M., Ariz., s. Calif., Mex., Guat. and offshore islands; introd. in Tenn. and S.D.—var *longidentata* Perry differs in its more open growth, bipinnatifid leaves of characteristic appearance and calyx teeth 2-2.5 mm. long; open ground, fields, arroyo banks and mesquite pastures, often covering large areas, from the s. Plains Country e. to Wharton and Denton Cos., s. to Cameron Co., Feb.-Nov.; also N.M. and n. Mex.—var. *pubera* (Greene) Perry differs in its more or less prostrate compact habit and the ultimate segments of the leaves linear-oblong and strongly revolute-margined; plains and low mts., the Trans-Pecos, Plains Country and Rio Grande Plains, Feb.-Aug.; also N.M. and Ariz.

33. *Verbena racemosa* Eggert. PALE VERVAIN. Stems several from a common base, ascending-erect, branched, pubescent, sometimes blooming when only 25 mm. tall; leaves small, bipinnatifid or trifid, the segments deeply cleft, the ultimate segments linear, somewhat pubescent or hirtellous on both surfaces; spikes subsessile, elongate but still dense at maturity; bractlets scarcely as long as the calyx, lanceolate, acuminate, ciliate; calyx 5-6 mm. long, sparsely glandular-hirtellous, the teeth short-acute-subulate; corolla white or essentially so, the tube 7-9 mm. long, puberulent or glabrous outside, the limb 5-6 mm. wide. Deserts, low valleys, foothills and roadsides, from Trans-Pecos e. to LaSalle, Bexar and Houston cos., Jan.-June; also N.M. and n. Mex.

34. *Verbena Gooddingii* Briq. SOUTHWESTERN VERVAIN, SOUTHWESTERN VERBENA. Stems usually several from a common base, erect or decumbent-ascending, often forming mats, gray-green, branched, densely white-villous, often glandular; leaves 3-5 cm. long, tapering at base into a short margined petiole, 3-cleft, the divisions coarsely toothed or incised, gray-green, usually villous-hirsute on both surfaces, slightly or not revolute-margined, the venation rather prominent beneath; spikes pedunculate, fasciclelike in anthesis, later somewhat elongating, white-villous; bractlets usually a little shorter than the calyx, lanceolate, acuminate, villous-hirsute, long-ciliate; calyx 8.5-11 mm. long,

villous-hirsute, more or less glandular, the subulate lobes unequal; corolla showy, blue to pink or lavender, the tube slightly surpassing the calyx, pubescent outside, the limb 8-12 mm. wide, segments retuse. *Glandularia Gooddingii* (Briq.) Solbrig. Washes, mts., grasslands, pinyon forests, open or brushy flats and riverbeds, Rio Grande Plains (Uvalde Co.), Feb.-Oct.; also Nev., Ut., N.M., Ariz., s. Calif. and n. Mex.

35. *Verbena pumila* Rydb. PINK VERVAIN. Stems usually several from a common base, branched, decumbent-ascending, hirsute, often finely glandular; leaves 1.5-3 cm. long, obtusely triangular, truncate at base and cuneately contracted into a short narrowly margined petiole, trifid, sometimes lobed, the divisions variously incised, appressed-hirsute on both surfaces; spikes short-pedunculate or sessile, rather compact, hardly elongating; bractlets almost as long as the calyx, linear-lanceolate, hispid-hirsute; calyx 6 mm. long, pubescent, hispidulous on the veins, sometimes finely glandular, the short lobes subulate; corolla inconspicuous, small, pink or lavender to blue, the tube slightly surpassing the calyx, 8-10 mm. long, slightly or not pubescent outside, the limb 3-5 mm. wide; anther glands minute or absent. Fields, prairies, chaparral, meadows, pastures, river terraces, woods, sandy slopes and hillsides, practically throughout Tex., from the Trans-Pecos, s. to Cameron Co., e. to Wharton and Walker cos., n. to Grayson, Childress, Armstrong and Bailey cos., Jan.-Aug.; also Ark., Okla., N.M. and n. Mex.—f. *albida* Moldenke differs in its white corollas; s. and w. Tex.

2. STYLODON RAF.

CAROLINA VERVAIN

A monotypic genus of the southern United States.

1. *Styloдон carneus* (Medic.) Moldenke. Gray-pubescent perennial herbs to about 8 dm. high, with simple or sparingly branched tetragonal puberulent stems; leaves opposite, spatulate to oblong or the upper oblong-hastate, sessile, to about 12 cm. long and 4 cm. wide, shallowly serrate-dentate, scabrous above, less harsh and spreading-pubescent along the prominently reticulate venation beneath; spikes terminal, pedunculate, mostly solitary, sometimes ternate, slender with crowded tips, more open in fruit; bractlets lanceolate, about half as long as the calyx, glandular-pubescent; flowers hypogynous, perfect, complete, zygomorphic; calyx gamosepalous, tubular-campanulate, 5-costate, its rim sharply 5-lobed, about 5 mm. long, glandular-pubescent, the lobes unequal, acute; corolla gamopetalous, salverform, usually blue or pink, slightly longer than the calyx, pubescent outside, the limb 5 mm. wide, the 5 lobes subtruncate; stamens 4, inserted at or above the middle of the corolla tube, included, didynamous; filaments extremely short; anthers unappendaged, 2-celled, the thecae parallel; pistil one, included; style short; stigma very shortly 2-lobed, the larger lobe stigmatiferous, the smaller one toothlike; ovary 4-celled, each cell 1-ovulate; ovules erect; fruit nutlike, ridged, with 4 broad plane surfaces at the top which form a caplike beak; cocci 4, not readily separating. Sandy barrens, woods and upland pinelands, from Newton and Jefferson cos. s.w. to Kleberg Co., Apr.-Sept.; also N.C. to Fla. and La.

3. LANTANA L.

LANTANA

Mostly erect herbs or shrubs, sometimes decumbent or scandent, usually more or less scabrous and hirtous-pubescent or tomentose with simple hairs; leaves opposite or ternate, dentate, often rugose; inflorescence in the form of dense cylindrical spikes or contracted to form heads, usually axillary, pedunculate; flowers red, yellow, blue or white, often fading to various other shades, sessile, borne in the axils of solitary bractlets that are oblong to lanceolate or ovate, acuminate, spreading or subimbricate; calyx small, membranous, truncate and entire or sinuate-dentate; corolla hypocrateriform, the tube cylindrical, slender, equal in diameter throughout or slightly amplified above, the limb spreading, regular or obscurely 2-lipped, 4- or 5-fid, the lobes broadly obtuse or retuse; stamens 4, didynamous, inserted at about the middle of the corolla tube, included; anthers ovate, with parallel thecae; ovary 1-carpellary, 2-celled, each cell 1-ovulate; style usually short; stigma rather thick, oblique or sublateral; ovules basal and erect or attached laterally near the base of each cell; fruit drupaceous, the exocarp usually more or less

fleshy (rarely dry), the endocarp hard, 2-celled or splitting into two 1-celled pyrenes; seeds without endosperm.

A genus of about 160 species and 75 named varieties and forms, mostly natives of tropical and subtropical America; a few also in tropical Asia and Africa.

1. Bractlets narrow-lanceolate to oblong or linear; heads large, mostly 2-3 cm. wide; corolla mostly orange, yellow or red, its tube to 1 cm. long, the limb to 9 mm. wide; leaves broad, mostly 20-70 mm. wide (2)
1. Bractlets broadly ovate; heads smaller, mostly 1-1.5 cm. wide; corolla mostly magenta, lilac, pink or white, large or small; leaves mostly narrow, 6-28 mm. wide (5)
- 2(1). Pubescence (if any) of branches and leaves usually very sparse, not glandular (3)
2. Pubescence of branches and leaves usually very dense, white, often glandular 3. *L. scorta*.
- 3(2). Leaves usually relatively small, mostly 3-5 cm. long and 2-4 cm. wide, very coarsely toothed; native 1. *L. horrida*.
3. Leaves usually relatively large, mostly 5-11 cm. long and 2.5-7 cm. wide, regularly and more abundantly toothed, the teeth appressed; introduced (4)
- 4(3). Young twigs mostly glabrate or short-puberulent . . 2. *L. Camara*.
4. Young twigs rather densely white-hispid 2. *L. Camara* var. *mista*.
- 5(1). Stems and branches usually procumbent or decumbent; corolla large, showy, magenta or lilac when newly opened, the tube 10 mm. long, the limb 8-18 mm. wide; introduced 4. *L. montevidensis*.
5. Stems and branches usually erect or ascending; corolla smaller, not especially showy, mostly white, pink or yellow when newly opened, the tube 4-6 mm. long, the limb about 3 mm. wide; native (6)
- 6(5). Leaf blades usually very densely canescent-tomentose or velutinous beneath, upper surface more or less bullate, the marginal teeth small and rounded 5. *L. velutina*.
6. Leaf blades appressed-strigose or short-pubescent beneath, upper surface not bullate, the marginal teeth coarse or appressed, acute (7)
- 7(6). Mature inflorescence always much shorter than the subtending leaves; lower leaf surface densely black-punctate; fruit fleshy . . . 6. *L. Frutilla*.
7. Mature inflorescences often longer than the subtending leaves; lower leaf surface not black-punctate; fruit dry (8)
- 8(7). Leaf blades finely crenate or subentire; peduncles mostly shorter than the subtending leaves 7. *L. microcephala*.
8. Leaf blades sharply serrate; peduncles mostly greatly surpassing the mature subtending leaves (9)
- 9(8). Leaf blades sparsely strigose beneath with distinct straight stiff hairs; marginal teeth of leaf narrow, regularly attenuate and very sharp, often greatly appressed 8. *L. achyranthifolia*.
9. Leaf blades densely strigose-pubescent beneath with massed soft hairs that are not notably straight or stiff; marginal teeth of leaf usually broadly triangular, very abruptly acute (10)
- 10(9). Corolla pink 9. *L. macropoda*.
10. Corolla white with a yellow "eye" 9. *L. macropoda* f. *albiflora*.

1. *Lantana horrida* H.B.K. TEXAS LANTANA, HIERBA DE CRISTO, CALICO BUSH. Shrub to 2 m. tall, much-branched; stems and branches unarmed or with many stout recurved prickles, glabrous to sparsely hirsute, the younger ones often more hirtellous; petioles 2-12 mm. long, pilose-hirsute; leaf blades ovate or subrotund-ovate, usually 3-5 cm. long and 2-4 cm. wide, acute or obtuse, usually truncate or subtruncate at base, often very shortly cuneate-attenuate into the petiole, very coarsely serrate from apex almost to base with large rather irregular widely spreading acute or obtuse teeth, short-strigose and very scabrous above, subglabrate to puberulent or hirtellous on the venation beneath, often sub-bullate above;

peduncles 3-9 cm. long, usually slightly surpassing the leaves, subglabrate to hispidulous; bractlets narrow-lanceolate or oblong, 4-9 mm. long, 1-2 mm. wide, acute, strigillose, the innermost usually one half the length of the corolla, the outermost often larger and forming an involucre subequalling the corolla tube; heads hemispheric, 2-3 cm. wide, densely many-flowered, not elongating; corolla very showy, yellow to orange or red, the tube 7-10 mm. long, densely pubescent outside, limb 5-9 mm. wide; fruit black or dark-blue, edible. Fields, thickets, swamps, rich sandy woods, scrub, gravelly hills, flats, chaparral and roadsides, often in large patches, almost throughout Tex. except the n.w.; also cult. and in N.M., Ariz., Calif., n. Mex., and introd. in N.C. and Miss.

2. *Lantana Camara* L. WEST INDIAN LANTANA, ALFOMBRILLA HEDIONA. Branching shrub to 2 m. tall; stems and branches usually unarmed or with only comparatively few weak prickles, the young parts puberulent or short-pubescent to subglabrate; petioles 5-20 mm. long, glandular-puberulent; leaf blades ovate to oblong-ovate, 5-11 cm. long, 2.5-7 cm. wide, acute or short-acuminate (rarely obtuse), crenate-serrate with abundant and regular appressed teeth, acutely narrowed or abruptly rounded to a subcuneate base, reticulate-rugose and decidedly scabrous above, short-pubescent mostly on the venation beneath; inflorescence shorter than to equaling or surpassing the leaves; heads hemispheric, 2-3 cm. wide, densely many-flowered, not elongating; peduncles 2-8 cm. long, appressed-puberulent; bractlets oblong or narrow-lanceolate, 4-7 mm. long, 1-1.5 mm. wide, equal, acute, usually about one half the length of the corolla tube, appressed-strigose; corolla very showy, yellow to orange or red, the tube 10 mm. long, barely enlarged above the middle, slightly curved, puberulent outside, limb 6-9 mm. wide; drupes black. Widely cult. and tending to escape, cen. and s. Tex.; Berm. and Fla. through the W.I.; less common in C.A. and S.A.; introd. in trop. Asia and Afr.; widely cult.—var. *mista* (L.) Bailey differs in having the youngest parts rather densely spreading-hirsute; known from Travis Co.; found practically throughout the range of the species.

3. *Lantana scorta* Moldenke. Extremely variable shrub, to 2 m. tall; branches often armed with few or many strong recurved prickles or unarmed, the younger parts usually densely hirsute-hispid with white wide-spreading hairs, often glandular; petioles 4-17 mm. long, usually densely white-hirsute, often glandular; leaf blades ovate or broadly ovate, 15-75 mm. long, 12-55 mm. wide, acute or subacuminate, more rarely obtuse or rounded, regularly crenate-serrate from almost the base to apex with either small and appressed antrorse or large and coarse spreading teeth, acute to truncate or subcordate at base and cuneately prolonged into the petiole, scabrous and densely hirsute or antrorsely substrigose-pilose above, mostly velutinous or densely canescent-tomentose beneath, sometimes merely pilose-pubescent on the larger venation; peduncles usually far surpassing the leaves, 35-85 mm. long, usually densely hirsute-hispid, often glandular; heads hemispheric, 1-2.5 cm. wide, not elongating; bractlets numerous, linear or oblong to lanceolate, to 12 mm. long, 1-3.5 mm. wide, densely white-hirsute to appressed-strigose; corolla surpassing the bractlets, red or orange, the tube 10-16 mm. long, densely short-pubescent outside. Thickets, prairies, banks and roadsides, Rio Grande Plains (Hidalgo Co.), Feb.-June; widespread in Mex.; may represent a hybrid population.

4. *Lantana montevidensis* (Spreng.) Briq. WEEPING LANTANA, TRAILING LANTANA, POLECAT-GERANIUM. Stems many from a woody base, much-branched, weak, often mat-forming; branches prostrate or decumbent to arching and vinelike, to 1 m. long, rooting at the nodes, strigose or hirtellous; petioles about 4 mm. long; leaf blades ovate or elliptic-ovate to rhomboid-lanceolate, 1-3 cm. long, 8-16 mm. wide, acute or subacute, crenate or coarsely serrate, abruptly narrowed or truncate at base and cuneate into the petiole, rugose and scabrous-pubescent or pilose-hirsute above, strigose on the venation or densely tomentulose beneath, densely resinous-glandular; heads long-pedunculate, plainly involucrate, at first hemispheric, later somewhat elongating and finally oblong; peduncles filiform; bractlets large, broadly ovate, concave, acuminate, spreading, strigose-hirtellous, ciliate, densely resinous-glandular, one half as long as the corolla, the outer ones somewhat larger; corolla magenta or lilac to rose or purple, with a white "eye," showy, the tube 8-10 mm. long, almost straight, slightly ampliate above, puberulent and resinous-dotted outside, limb 8-18 mm. wide, lower lobe elongate; mature drupes violet-black. *L. Sellowiana* Link & Otto, *L. delicatissima* Poit. Roadsides, waste places, fencerows, pine-lands and woods, s.e. Tex. (Orange Co.), Feb.-June; introd. from s. S.A.; also established in Ga., Fla., Ala., Calif., C.R., Cuba, W.I. and n. S.A.; widely cult.

5. *Lantana velutina* Mart. & Gal. VELVET LANTANA, CONFITURILLA BLANCA, CONFITE BLANCA, OREGANO XIU. Small diffusely branched shrub to 2 m. tall, with rhubarb odor; branches unarmed, slender, rather densely short-pubescent or tomentose, less so in age; petioles 1-9 mm. long, densely gray-tomentose; leaf blades ovate or elliptic-ovate, 1-4 cm. long, 7-28 mm. wide, acute to short-acuminate or rounded, regularly crenate with small obtuse antrorse teeth, cuneately narrowed into the petiole, mostly reticulate-rugose or bullate and densely velutinous-pubescent above, mostly very densely canescent-tomentose or velutinous beneath; peduncles equaling or surpassing the leaves, 1-7.5 cm. long, rather densely short-pubescent; heads at first hemispheric, later slightly ovate-elongate; bractlets large, conspicuous, closely imbricate, broadly ovate, the outermost to 12 mm. long and 8 mm. wide, subacute or obtuse, venose, densely appressed-pubescent or velutinous, shorter than or surpassing the corolla; corolla white, turning lavender or pinkish in age, yellow in the throat, fragrant, the tube 6 mm. long, densely strigose-pubescent outside (as are also the lobes); fruit at first pink, then bluish-black, edible. Open woods, thickets, mesas, sandy loams, cliffs and dry soil on hills, Webb Co., Feb.-June; widespread in Mex. and C.A.

6. *Lantana Frutilla* Moldenke. FRUTILLA LANTANA, FRUTILLA. Shrub to 2 m. tall; branches slender, very sparsely strigillose-pubescent, elongate; petioles 3-5 mm. long, sparsely whitish-strigillose; leaf blades ovate, 1.8-6 cm. long, 1-3 cm. wide, acute or subacuminate, uniformly serrate from widest part to apex with rather appressed acute or bluntish teeth, rounded at base or abruptly acuminate and prolonged into the petiole, sparsely strigillose above, densely short-pubescent and black-punctate beneath; heads 1-2 cm. long, to 1 cm. wide, densely many-flowered, slightly elongating in age, on peduncles that are always much shorter than the subtending leaves; bractlets conspicuous, involucrate, ovate, 6 mm. long and 3 mm. wide, acute, strigillose, spreading, about equaling the corolla tube; corolla white with a yellow center, fading to pinkish, the tube 6-7 mm. long, densely strigillose outside, limb 3-4 mm. wide; fruit lavender or bright-purple. Woods, high matorral, chaparral, llanos, shady gullies and steep hillsides, Cameron Co.; widespread in Mex.

7. *Lantana microcephala* A. Rich HAMMOCK LANTANA, HIERVADA JAVILLAS, OREGANO XIU, TORONJIL, SAC-CHILI. Slender unarmed shrub to 25 dm. tall; stems and branches whitish, rather densely white-strigose with appressed antrorse hairs (less so in age); petioles 2-8 mm. long, densely appressed-strigose with white antrorse hairs, mostly winged; leaf blades lanceolate or ovate, to 6 cm. long and 25 mm. wide, acute or acuminate, regularly and finely crenate with blunt antrorse teeth or subentire, long-acuminate at base and attenuate into the petiole, densely white-strigose on both surfaces (especially beneath), not bullate but venation often impressed above and prominent beneath; peduncles shorter than or surpassing the leaves, 9-50 mm. long, densely appressed-strigose; heads globose at first, later oblong, 4-12 mm. long, 6-13 mm. wide; bractlets plainly imbricate, 4-ranked, ovate or broadly ovate, involucrate, acuminate, the lowermost to 6 mm. long and 3 mm. wide, densely white strigose, keeled; corolla white with a yellow-throat, slightly surpassing the inner bractlets, tube 4-5 mm. long, strigose-puberulent outside, limb 2-lipped, 3 mm. wide; drupes dry, 1.5 mm. in diameter. *L. citrosa* (Small) Moldenke, *Gonostachyum citrosum* Small. Hammocks, forests, brushlands and roadsides, Rio Grande Valley and coastal Tex.; also s. Fla., Mex. and Guat.

8. *Lantana achyranthifolia* Desf. BRUSHLAND LANTANA, CARAQUITO BLANCO, CARIACO DE SAN JUAN, FRUTILLA BLANCA, OREGANILLO CIMARRÓN. Shrubby, to 2 m. tall; stems unarmed; branches slender, elongate, ascending, light-yellowish-green, densely appressed-strigose with stiff straight white antrorse hairs; leaves often ternate; petioles 1-10 mm. long, densely strigose; leaf blades narrow-lanceolate to broadly ovate, 2.5-8 cm. long, 15-53 mm. wide, acute or acuminate, coarsely and sharply serrate with usually narrow and regularly attenuate teeth, acuminate or acute at base, scabrous-strigose on both surfaces with closely appressed antrorse whitish or yellowish hairs, stiffer and more scattered beneath, denser on the large venation, resinous-punctulate beneath; peduncles erect or ascending, 4-14 cm. long, far-surpassing the leaves, 2 or 3 per node, densely appressed-strigose; heads at first hemispheric, showy, later ovoid-cylindric, 1-2 cm. long and wide, not greatly elongating after anthesis; bractlets broadly ovate, plainly imbricate and involucrate, attenuate-acuminate, often red, the lowest to 12 mm. long and 8 mm. wide, appressed-strigose and resinous-punctate; corolla equaling or slightly surpassing the inner

bractlets, somewhat shorter than lowest bractlets, opening yellow, turning white with yellow or orange center, fading to violet, blue or purple, the tube 5 mm. long, strongly curved, very densely puberulent outside, limb bilabiate, 3 mm. wide; fruit dry, entirely enclosed by the fruiting calyx. Canyons, valleys, fields, arroyo margins and meadows, San Patricio Co.; widespread in Mex.; also Guat. and S.A.; introd. in Java.

9. *Lantana macropoda* Torr. DESERT LANTANA, HIERBA NEGRA, MEJORANA, YERBA DEL CRUSTO. Aromatic shrub to 15 dm. tall; stems and branches slender, gray, densely white-strigose on younger parts; petioles 2-10 mm. long, densely white-strigose with antrorse hairs; leaf blades ovate or lanceolate, 5-35 mm. long, mostly 6-15 mm. wide, sharply acute, sharply serrate from apex almost to base with coarse broadly triangular often rather spreading teeth, densely white-strigose above, more densely pubescent beneath with soft irregular whitish or yellowish hairs and densely resinous-punctate; peduncles much-surpassing the leaves, to 10 cm. long, white-strigose; heads at first hemispheric, later elongating to 2 cm., 1-1.5 cm. wide; bractlets broadly ovate, the lowermost to 7 mm. long and 4 mm. wide, long-acuminate, densely white-strigose, closely imbricate, resinous-punctate; corolla pink or lavender to purple, often with a yellow "eye," the tube 4-5 mm. long, limb 3 mm. wide; fruit thin-fleshed, translucent, almost dry. Gravelly hills, dry rocky slopes, flats, mesas, deserts, limestone bluffs, dry open ground, valleys, pastures and fencerows, Trans-Pecos and Rio Grande Plains and Valley e. to Fort Bend and Houston cos., Feb.-Nov.; also N.M., Ariz. and n. Mex.—f. *albiflora* Moldenke differs in its white corollas, often with a yellow eye; Starr and Cameron cos., Feb.-May; also n. Mex.

4. LIPPIA HOUST.

LIPPIA

Erect bushes, shrubs or subshrubs; leaves opposite or ternate, rarely alternate; inflorescence spicate, solitary or fascicled and axillary or aggregate into terminal corymbs or panicles, the spikes mostly contracted into heads or cylindric, usually not conspicuously elongated in fruit, very dense-flowered; flowers small, sessile, borne singly in the axils of rather large ovate or lanceolate bractlets, often more or less 4-ranked; calyx small, membranous, ovoid-campanulate or compressed and 2-carinate or 2-alate, its rim 2- or 4-fid or 4-dentate; corolla salverform, its tube cylindric, straight or incurved, very slender, slightly exerted from the calyx or rarely elongate, equal in diameter throughout or ampliate above, the limb oblique, spreading, somewhat 2-lipped, 4-parted, the broad lobes often retuse; stamens 4, didynamous, inserted at about the middle of the corolla tube, included or slightly exerted; anthers ovate, unappendaged, the cells parallel; ovary 2-celled, each cell 1-ovulate; style often short; stigma rather incrassate, oblique or recurved; ovules basal and erect or affixed laterally near the base; fruit small, dry, included by the calyx and sometimes adnate to it, dividing into 2 pyrenes at maturity, the pericarp papery and hard, the exocarp membranous and rarely distinct from the pyrenes; seeds without endosperm.

A genus of about 206 species and 44 named forms and varieties, widely distributed in subtropical and tropical America; a few also in tropical portions of the Old World.

1. Peduncles mostly solitary in the leaf axils, usually 2 per node; leaves mostly cuneate at base 1. *L. alba*.
1. Peduncles 2 or 3 in each leaf axil, 4 to 6 per node; leaves mostly rounded or subcordate at base 2. *L. graveolens*.

1. *Lippia alba* (Mill.) N. E. BR. BUSHY LIPPIA, ALFOMBRILLA, CIDRILLA, HIERBA BUENA, ORÉGANO DE BURRO, SALVA DO BRASIL, SALVA COLORADO, TÉ DE CASTILLA, TORONJIL DE ESPAÑA, HIERBA NEGRA, HIERBA DEL NEGRO. Aromatic shrub to 2 m. tall, usually much-branched, with long rooting suckers at base; branches elongate, slender, ascending, pubescent; leaves often ternate; petioles 3-8 mm. long, gray-pubescent; leaf blades ovate or oblong, 2-7 cm. long, 12-23 mm. wide, acute or obtuse, serrate or serrulate except at base, cuneately narrowed into petiole at base, puberulent or strigose-hirtellous and rugose (when mature) above, densely short-pubescent or tomentose beneath; inflorescence axillary, capitate, mostly much shorter than the leaves or only subequaling the petiole, solitary or rarely paired in all the upper leaf axils; heads subglobose or short-oblong, 8-12 mm. long; bractlets ovate, 3-5 mm. long, the lowermost 3-3.5 mm. wide, nearly as long as the corollas; corolla purple to violet, pink or white, the tube 4-5 mm. long. *L. geminata*

H.B.K. Woods, river banks and resacas, Hidalgo and Cameron cos. n.e. to Wharton Co., Mar.-Oct.; widespread in W.I., Mex., C.A. and S.A., introd. elsewhere, widely cult.

2. *Lippia graveolens* H.B.K. REDBRUSH LIPPIA, HIERBA DULCE, OREGANO CIMARRÓN, ROMERILLO DE MONTE, TÉ DEL PAÍS, TARBAY. Slender aromatic shrub to 3 m. or tree to 9 m. tall; branchlets slender, villosulous-pubescent, densely resinous-punctate; petioles 2-20 mm. long, rather densely appressed-pubescent; leaf blades oblong or ovate-oblong to elliptic, 1-6.5 cm. long, 5-30 mm. wide, mostly obtuse or rounded (sometimes acute), regularly crenate from base to apex with closely set blunt teeth, rounded or subcordate at base, sometimes abruptly acute and slightly prolonged into the petiole, reticulate-rugose or sub-bullate above and rather densely strigose-hirsutulous, puberulent and resinous-glandular to gray-tomentose beneath; peduncles 4 to 6 per node, usually equaling or slightly surpassing the petioles, spreading, appressed-pubescent or strigose; spikes oblong, 4-12 mm. long; bractlets plainly 4-ranked, conduplicate-carinate, narrow-lanceolate, imbricate, connate at base, usually wide-spreading or reflexed at apex in fruit, acute, hirsute-tomentose, resinous-glandular, the margins and keel more densely white-villous, subequaling the corolla tube; corolla yellowish or white with a yellow "eye," the tube 3-6 mm. long, gray-strigose outside. *L. Berlandieri* Schauer, *Goniostachyum graveolens* (H.B.K.) Small. Dry and rocky hills, valleys, arroyos, chaparral and open desert scrub, Trans-Pecos, Rio Grande Plains and Valley, n.e. to Austin and Houston cos., Mar.-Dec.; also N.M., Mex. and C.A.

5. PHYLA LOUR. FROG-FRUIT

Perennial procumbent or creeping herbs, with trailing or ascending stems, sometimes somewhat woody at base or even shrubby, subglabrate or appressed-strigose with more or less cinereous malpighiaceus hairs; leaves opposite, variously dentate except at the base, flat or pinnately plicatulate above; inflorescence spicate, axillary; spikes cylindric, very densely many-flowered, usually greatly elongate in fruit, solitary or paired or ternate in the leaf axils, never aggregated into corymbs or panicles; flowers small, sessile, borne singly in the axils of small cuneate-obovate or flabelliform bractlets, not at all 4-ranked; otherwise with characters of *Lippia*.

A genus of about 10 species and 10 named forms and varieties, widely distributed in subtropical and tropical America; a few introduced in the warmer parts of the Old World.

- 1. Leaf blades mostly widest at or below the middle, toothed from below the middle to the apex (2)
- 1. Leaf blades mostly widest toward the apex and toothed only near the apex (4)
- 2(1). Leaf blades mostly oblong-lanceolate or oblong-ovate, mostly widest at or near the middle, not plicatulate, the teeth antrorsely appressed, extending below the widest part of the leaf 1. *P. lanceolata*.
- 2. Leaf blades mostly ovate or triangular-ovate to rhomboid, often plicatulate, widest below the middle, the teeth coarse and divergent, not extending below the widest part of the leaf (3)
- 3(2). Mature leaves mostly to 75 mm. long and 20 mm. wide 2. *P. strigulosa*.
- 3. Mature leaves mostly less than 15 mm. long and 10 mm. wide 2. *P. strigulosa* var. *sericea*.
- 4(1). Leaf blades with 1 to 4 pairs of remote salient teeth (5)
- 4. Leaf blades with numerous pairs of small mostly antrorse teeth (6)
- 5(4). Bractlets 2-3 mm. long, closely imbricate, acute, not conspicuously reflexed; peduncles 1.5 to 4 times as long as the subtending leaf during anthesis; heads 5-10 mm. thick, becoming elongate-cylindric or oblong in fruit; fruit obovoid 3. *P. incisa*.
- 5. Bractlets 5 mm. long, wide-spreading, the apex long-acuminate and finally reflexed; peduncles 0.7 to 1.5 times as long as the subtending leaf during anthesis; heads 7-12 mm. wide, usually not elongating in fruit; fruit oval 4. *P. cuneifolia*.

- 6(4). Leaves uniformly elongate, to 5.5 cm. long, 4-10 mm. wide 5. *P. nodiflora* var. *longifolia*.
6. Leaves mostly shorter, cuneate-spatulate to rhomboid, 1-3 cm. long (7)
- 7(6). Midrib and secondaries usually prominent beneath, often very conspicuous, often impressed above; blades often large and elliptic or rhomboid, coarsely toothed ... 5. *P. nodiflora* var. *reptans*.
7. Midrib and secondaries usually obscure or indiscernible on both surfaces; blades usually small and spatulate or cuneiform (8)
- 8(7). Plants usually densely matted, more or less densely strigose-canescens throughout; leaves mostly very small and cuneiform, usually thin-textured and few-toothed, sometimes entire or subentire 5. *P. nodiflora* var. *rosea*.
8. Plants usually creeping and wide-spreading, open in growth, often with ascending branches, usually green and only finely strigillose; leaves mostly larger, cuneate-spatulate or spatulate to obovate, thick-textured, usually more abundantly toothed (9)
- 9(8). Teeth on leaf blades mostly rather large, coarse and salient-spreading 3. *P. incisa*.
9. Teeth on leaf blades mostly small and appressed, usually forward-pointing 5. *P. nodiflora*.

1. *Phyla lanceolata* (Michx.) Greene. NORTHERN FROG-FRUIT. Stems procumbent or ascending, to 6 dm. long, simple or somewhat branched, often rooting at the nodes, glabrous or obscurely white-strigillose with closely appressed hairs; petioles 5-10 mm. long or obsolete, obscurely appressed-strigillose; leaf blades bright-green on both surfaces, oblong to oblong-lanceolate or ovate, 18-75 mm. long, 5-30 mm. wide, acute or subacute, sharply serrate to below the middle, widest at or below the middle, narrowed to the cuneate base, rather obscurely appressed-strigillose on both surfaces, venation flat but conspicuous above, rather prominent and very conspicuous beneath; inflorescence equaling or surpassing the leaves, peduncles 4-9 cm. long, rather sparsely and obscurely white-strigillose; heads at first globose, later cylindrical and elongating to 35 mm. and 5-7 mm. wide; bractlets obovate, closely imbricate, 3 mm. long, acute, appressed-strigillose; corolla pale-blue, purplish or white. *Lippia lanceolata* Michx. Moist soil of river bottoms, lake shores and coastal marshes, from Bowie to Jefferson cos. w. to Wise, Callahan and Bexar cos., n. to Hemphill and Hutchinson cos. in the Panhandle, and s.w. to Victoria and Matagorda cos., May-Oct.; also Ont. to Minn., N.J., Ill., Kan., Fla., Calif. and n. Mex.

2. *Phyla strigulosa* (Mart. & Gal.) Moldenke. DIAMOND-LEAF FROG-FRUIT, TURREHEMBRA, HIERBA BUENA MONTES. Procumbent, freely branched from the base; branches rooting at the nodes, to 2 m. long, often sulcate, often reddish to purplish toward the base, gray-strigillose with closely appressed antrorse hairs, the tips ascending or erect; petioles 1-5 mm. long, mostly winged, rather obscurely canescent-strigillose or glabrescent; leaf blades mostly broadly ovate or triangular-ovate to rhomboid or ovate-elliptic, mostly conspicuously widest below the middle, to 75 mm. long and 2 cm. wide, rounded or acute (in outline) at apex, abruptly acuminate at base and prolonged into the petiole, conspicuously and regularly coarse-dentate from apex to the widest part with sharply acute or apiculate broadly triangular rather divergent teeth (their margins often thick and involute), both surfaces rather densely but microscopically canescent-strigillose, often plicatulate, the larger venation white and very prominent beneath; peduncles 25-55 mm. long, deeply sulcate, densely canescent-strigillose or glabrescent; heads 4-8 cm. long, later elongating; bractlets ovate to obovate, 3 mm. long, 1.5 mm. wide, sharply acute or acuminate, densely canescent-strigose, strongly costate; corolla about 3 mm. long, white, sometimes lavender- or purple-tinged in age, limb 1.5 mm. wide. *Lippia strigulosa* Mart. & Gal., *P. yucatanana* Moldenke. Fields, woods, open ground, swamps, sandy streambanks and muddy hollows, Rio Grande Plains and Valley, Feb.-May; widespread from Mex. and Gr. Ant. through Virg. I., C.A. and S.A.—var. *sericea* (O. Ktze.) Moldenke differs in having the mature leaves to 15 mm. long and 1 cm. wide. Incl. var. *parviflora* (Moldenke) Moldenke. Rio Grande Plains and Valley, Feb.-May; also Mex., Bah. I., W.I., Trin. and Venez.

3. *Phyla incisa* Small. TEXAS FROG-FRUIT. Stems mostly prostrate, often swollen and rooting at the nodes, simple or branched, often purplish, appressed-strigillose; branches

decumbent to ascending or erect, abundantly appressed white-strigose; petioles usually obsolete or 1-3 mm. and winged; leaf blades often thick-textured, narrow-oblong or cuneiform to broadly obovate, very variable, 1-5 cm. long, 2-15 mm. wide, acute to obtuse or rounded (in outline) at apex, usually with only 1 to 4 pairs of coarse and saliently spreading teeth near the apex, cuneate from the middle or above the middle to the base, appressed-strigillose on both surfaces with small inconspicuous white hairs, secondary venation mostly obscure on both surfaces; inflorescence usually much-surpassing the subtending leaves; peduncles 2-9 cm. long, appressed-strigillose; heads at first globose, later cylindric and elongating to 3 cm., 5-10 mm. wide; bractlets obovate, 2-3 mm. long, closely imbricate, acute, abundantly white-strigillose; corolla white with yellow center, the tube 2-2.5 mm. long, limb 2 mm. wide. *Lippia incisa* (Small) Tidestr. Open ground, fields, pastures, clay or sandy flats, dry riverbanks and bottoms, damp shady woods and seashores, practically throughout Tex., Mar.-Nov.; also Colo., Okla. and Mo. to N.M., Ariz., s. Calif. and n. Mex.

4. *Phyla cuneifolia* (Torr.) Greene. WEDGE-LEAF FROG-FRUIT. Stems branching from a woody base, procumbent, often rooting at the nodes, to 1 m. long, sparsely appressed-strigillose with very short white hairs, somewhat zigzag, often with short erect branchlets at the nodes; leaves sessile, rigid, thick-textured, often with a fascicle of smaller ones in the axils, linear-oblongate or cuneiform, often canescent when young, 1-5.2 cm. long, 2-8 mm. wide, acute or subacute, with 2 to 8 very sharp and often salient teeth above the middle or rarely entire, gradually attenuate to the cuneate base, appressed-strigillose on both surfaces, secondary venation indiscernible on both surfaces; inflorescence shorter than or slightly surpassing the leaves; peduncles 8-50 mm. long, obscurely appressed-strigillose; heads at first globose, later cylindric and elongating to 2 cm., 8-12 mm. wide; bractlets conspicuous, obovate, 5 mm. long and 3 mm. wide, abruptly long-acuminate, at least the tip soon wide-spreading and finally reflexed, scarious on the upper margins, densely appressed-strigillose; corolla whitish or purplish, the tube 4-5 mm. long, limb 2-4.5 mm. wide. *Lippia cuneifolia* (Torr.) Steud. Plains and low prairies, frequent in Plains Country s. to Trans-Pecos, e. to Travis, Gonzales and Dallas cos., May-Sept.; also S.D., Neb. and Colo. to Ariz., s. Calif. and n. Mex.

5. *Phyla nodiflora* (L.) Greene. COMMON FROG-FRUIT, CAPE-WEED, TURKEY-TANGLE, MAT-GRASS, HERBA DE LA VIRGEN MARÍA. Stems prostrate, to 9 dm. long, mostly rooting at the nodes; branches procumbent or ascending, glabrate or puberulent to appressed-strigillose; petioles obsolete or 2-8 mm. long and cuneate-winged; leaf blades thick-textured, spatulate to oblanceolate or obovate, sometimes elliptic or cuneiform, 1-7.2 cm. long, 6-25 mm. wide, rounded or obtuse to subacute at apex, cuneate into the petiole, rather regularly sharply serrate above the middle with numerous appressed antrorse acute or acuminate teeth, glabrous or strigillose-puberulent on both surfaces, secondary venation practically indiscernible on both surfaces; peduncles usually much longer than the leaves, to 11.5 cm. long, appressed-puberulent or strigose with antrorse canescent hairs or glabrous; heads at first globose, cylindric in age and elongate to 25 mm., 6-9 mm. thick; bractlets closely imbricate, obovate or subrhomboid-cuneate, subequaling the corolla tube, often rather broadly membranous-margined toward the apex, mucronate-acuminate or muticous, glabrous or finely ciliate; corolla rose-purple or white, 2-2.5 mm. long, slightly surpassing the bractlets, slightly strigillose outside, limb exiguous. *Lippia nodiflora* (L.) Michx. Wet or moist soil, fields, clearings, hillsides, ditches, thickets and beaches, along the coast from Chambers to Cameron cos., inland to Kendall, Tom Green and Childress cos., May-Oct.; almost cosmopolitan in subtrop. and trop. regions of the Old World and New World; Pa. to Fla., Ky., Ark., La., Okla. and Calif.—var. *longifolia* Moldenke differs in having much more uniformly elongate leaves, the blades being oblanceolate-cuneate, to 55 mm. long and 4-10 mm. wide, and sharply spreading-dentate toward the apex; open sandy flats near the seacoast, Cameron Co.; also along the coasts of Mex., C.A. and w. S.A.—var. *reptans* (H.B.K.) Moldenke differs in usually being more densely strigose throughout and having the leaves thinner in texture, often rhomboid-elliptic, with the teeth usually more spreading and the larger venation firmer and more or less prominent beneath; low moist ground, shaded places, clearings, ditches, lawns and roadsides, from Presidio to Cameron and Chambers cos., n. to Dallas and Wichita cos., Feb.-Sept.; occurring sporadically almost throughout the range of the species.—var. *rosea* (D. Don) Moldenke (CARPET GRASS) differs in usually forming dense mats, more or less

densely and conspicuously canescent-strigose throughout, the leaves mostly very small, 5-28 mm. long and 2-9 mm. wide, cuneiform, usually thin-textured and few-toothed, sometimes entire or subentire; in dry sandy soil, lawns and roadsides, Harris Co., Jan.-Sept.; introd. from s. S.A., widely cult. in Calif. and elsewhere for lawns; escaped and naturalized in N.C., Fla., Tex., N.M., Ariz., Calif. and Mex.

6. ALOYSIA ORT. BEE-BRUSH

Usually sweet-aromatic shrubs; leaves opposite, simple, exstipulate, deciduous, the blades entire or toothed, not pinnatifid nor lobed; inflorescence centripetal, as axillary usually numerous slender mostly elongate loosely flowered spikes or racemes; flowers perfect, hypogynous, each subtended by a narrow inconspicuous or broader and conspicuous bractlet; calyx gamosepalous, tubular-campanulate, usually spreading-hirsute or -villous, not inflated at maturity, its tube angled, not flattened, the limb 4-lobed, lobes slender, subequal; corolla gamopetalous, zygomorphic, salverform, 2-lipped, the upper lip and the lobes of the lower lip subequal; stamens 4, didynamous, inserted at about the middle of the corolla tube, included; anthers 2-celled, unappendaged, the thecae parallel; pistil one, included; ovary 2-celled, each cell 1-ovulate; ovules erect; schizocarp small, dry, composed of 2 thin-walled cocci; seeds without endosperm.

A genus of about 41 species and 12 varieties in the southwestern part of the United States, Mexico and southern South America; one species introduced in the West Indies and widely cultivated elsewhere.

1. Leaf blades ovate or subrotund, many-toothed, densely tomentose beneath (2)
1. Leaf blades oblong to elliptic or obovate to obovate-oblong, entire or few-toothed, densely puberulent or strigillose beneath (3)
- 2(1). Leaf blades comparatively large, to 30 mm. long and 4-21 mm. wide, always ovate; spikes 5-16 cm. long, loosely flowered; twigs and petioles densely spreading-hirsutulous 1. *A. macrostachya*.
2. Leaf blades very small, 2-15 mm. long, 2-13 mm. wide, ovate or subrotund; spikes 1-4 cm. long, densely flowered; twigs and petioles densely appressed-puberulent 2. *A. Wrightii*.
- 3(1). Leaf blades narrowly oblong or elliptic, appressed-puberulent beneath 3. *A. gratissima*.
3. Leaf blades more broadly elliptic to obovate or oblong-elliptic, the larger ones usually 2- to 8-toothed, densely strigillose beneath and short-hispidulous along the venation 3. *A. gratissima* var. *Schulzae*.

1. *Aloysia macrostachya* (Torr.) Moldenke. WOOLLY BEE-BRUSH, VARA DULCE, CABRADOR CIMARRONA, ANGELITOS. Erect shrub to 2 m. tall; branches numerous, slender, erect, brittle, young parts densely hirsutulous with white hairs borne at right angles to the twigs, glandular; petioles 2-5 cm. long, densely white-hirsute; leaf blades ovate, 7-30 mm. long, 4-21 mm. wide, rounded, regularly crenate from widest part to apex with rather large rounded teeth, truncate or subtruncate at base, sub-bullate and densely strigose-hirsutulous with bulbous-based hairs above, scabrellous, densely white-tomentose beneath, resinous-glandular on both surfaces, larger venation usually impressed above and prominent through the tomentum beneath; inflorescence far-surpassing the leaves; spikes 5-12 cm. long, erect or ascending, loosely many-flowered; peduncles 1-3.5 cm. long, very densely white-hirsutulous, often with gland-tipped hairs; rachis densely white-hirsutulous; bractlets lanceolate, 2-3 mm. long, long-acuminate, densely hirsutulous; corolla pink to red or lavender, the tube 4-5 mm. long, limb 4 mm. wide. *Lippia macrostachya* (Torr.) Wats. In sand and scrub on gravel and limestone hills, Rio Grande Plains, Jan.-Oct.; also n. Mex.

2. *Aloysia Wrightii* (Gray) Heller. OREGANILLO. Aromatic branching shrub to 15 dm. tall; stems slender, brittle, the wood bright-yellow, bark thin and membranous, readily peeling off in long filamentous strips, young parts densely grayish-puberulent, the angles plainly deciduous-margined; petioles 1-4 mm. long or obsolete, densely appressed-puberulent with grayish or yellowish hairs; leaf blades usually very small, ovate or subrotund, 2-15 (rarely to 30) mm. long, 2-17 mm. wide, rounded, regularly crenulate

or crenate-serrate from apex almost to base with small rounded teeth, acute or obtuse to rounded or truncate at base, sub-bullate and strigillose-scabrous above, very densely tomentellous beneath with short appressed grayish or yellowish hairs and resinous-glandular, venation usually deeply impressed above and hidden by the tomentum beneath; inflorescence surpassing the leaves; spikes 1-4 cm. long, very densely many-flowered, the flowers closely crowded; peduncles subfiliform, 1-10 mm. long, usually much-abbreviated, densely puberulent; rachis subfiliform, densely puberulent; bractlets lanceolate, 1.5-2 mm. long, long-acuminate, densely puberulent; corolla white, 2.5 mm. long, puberulent outside, limb 2 mm. wide. *Lippia Wrightii* Gray. Rocky slopes, banks, ledges, arroyos, gullies, canyons, limestone hills, mesa slopes and desert scrub, frequent in Trans-Pecos, s. to Starr Co., n. to Tom Green Co., June-Oct.; also Nev., N.M., Ariz., s.e. Calif. and n. Mex.

3. *Aloysia gratissima* (Gill. & Hook.) Troncoso. COMMON BEE-BRUSH, WHITE BUSH, WHITE BRUSH, PALO AMARILLO, CEDRÓN, POLEO, CEDRÓN DEL MONTE, NIÑARUPÁ, RESEDA DEL CAMPO, ANGEL, FAVORITA, JAZMINILLO, OREGANILLO, ROMERILLO, VARA-DULCE, HIERBA DE LA PRINCESA. Slender shrub to 3 m. tall, much-branched; branches gray, stiff, grayish pulverulent-puberulent, often spinescent at the tips, the wood yellow; leaves often with fascicles of smaller ones in the axils; petioles 1-3 mm. long or obsolete; leaf blades narrow-oblong or elliptic to lanceolate-oblong, 3-27 mm. long, 2-8 mm. wide, obtuse or acute, sometimes mucronulate or emarginate, entire, attenuate into the petiole, minutely strigillose and scabrellose-pustulate above, very densely puberulent-pulverulent and resinous-punctate beneath, incanous, only the midrib usually prominent beneath; inflorescence greatly surpassing the leaves, erect or ascending, 2-7 cm. long, rather densely many-flowered; peduncles 5-15 mm. long, densely short-pubescent or puberulent; rachis densely short-pubescent; bractlets very small, lanceolate, 1-1.5 mm. long, acuminate, caducous, densely puberulent; flowers with strong vanilla odor; corolla white or tinged with violet, the tube 3.5 mm. long, glabrous outside, limb 3 mm. wide, loosely villous in the throat. *A. lycioides* Cham., *A. ligustrina* of auth., *Lippia lycioides* (Cham.) Steud., *L. ligustrina* of auth. Rock outcrops, desert grasslands, low places, rocky creek-beds, dry washes, woods, hillsides and rocky bluffs, practically throughout Tex. except the Plains Country, Mar.-Nov.; also N.M., Mex. and s. S.A.—var. *Schulzæ* (Standl.) Moldenke (BEE-BLOSSOM) differs in having broader leaf blades that are elliptic or obovate to oblong-elliptic, 5-18 mm. long, 3-7 mm. wide, obtuse or acute at apex and base, entire or the larger ones with 1 to 4 rather large and salient teeth on each side, tuberculate and strigillose or scabrous above, densely strigillose-pubescent beneath with longer more distinct hairs, often hispidulous on the larger venation with short ascending rather rigid hairs, usually revolute-margined, the midrib and secondaries usually impressed above on mature leaves; sandy soil, gravelly hillsides, chaparral thickets, arroyos and limestone bluffs, from Trans-Pecos to Cameron and Houston cos., Mar.-Nov. *A. ligustrina* var. *Schulzii* (Standl.) Moldenke, *Lippia ligustrina* var. *Schulzii* Standl.

7. BOUCHEA CHAM.

Annual or perennial herbs or low shrubs, densely pubescent or glabrous; leaves opposite or ternate, usually petiolate, sometimes sessile; blades usually serrate to serrate-crenate, rarely incised, dissected or entire; inflorescence centripetal, usually racemiform, rarely spicate, terminal (seldom axillary), elongate, loosely to densely many-flowered, bracteolate; flowers solitary in the axils of the bractlets, usually large and showy, usually pedicellate; bractlets subulate or lanceolate, sometimes enlarged and leaflike; calyx persistent, tubular, gamosepalous, 5-ribbed, the ribs terminating in 5 more or less unequal teeth; corolla gamopetalous, funnel- or salverform, zygomorphic, the tube cylindric, straight and erect or curvate, the limb oblique, spreading, unequally 5-lobed, the 2 posterior lobes shorter than the 3 anterior ones; stamens 4, didynamous, included, the posterior pair inserted at about the middle of the corolla tube and the anterior pair inserted somewhat above the middle; filaments short; anthers ovate to subcordate, 2-celled; pistil single, compound; style filiform; stigma 2-lobed, the anterior lobe club-shaped, the posterior lobe toothlike, on a level with the anterior pair of stamens; ovary 2-celled, oblong, each cell 1-ovulate; fruit dry, schizocarpous, linear, beaked, included by the mature calyx or exserted, separating into 2 cocci at maturity; cocci completely separate or coherent at

the base, the dorsal surface more or less reticulately ridged, the commissural surface plane, furrowed or ridged, sometimes a little roughened.

A genus of about 16 species and 6 named varieties, ranging from the southern United States and the Bahamas, through the West Indies, Mexico, and Central America to southern South America.

- 1. Leaves distinctly petiolate, coarsely serrate 1. *B. prismatica* var. *brevirostra*.
- 1. Leaves sessile, entire (2)
- 2(1). Leaves linear to narrow-lanceolate, thin, smooth ... 3. *B. linifolia*.
- 2. Leaves spatulate, thick, densely short-pubescent or rugose 2. *B. spathulata*.

1. *Bouchea prismatica* O. Ktze. var. *brevirostra* Grenz. Erect or sprawling herb, to 4 dm. tall; branches often numerous, ascending, medullose, minutely puberulent throughout, often more densely so and canescent on younger parts; leaves opposite, often with several smaller ones in the axils; petioles 11-25 mm. long, short-pubescent or puberulent; leaf blades mostly elliptic, 1-4 cm. long, 8-30 mm. wide, often falcate, obtuse or rounded, coarsely but regularly serrate with rather broad teeth to below the middle, acute or obtuse at base, rather densely short-pubescent on both surfaces when young, becoming more sparsely so or glabrate in age, larger venation plainly visible; spikes terminating stems and short axillary branches that often far surpass the terminal one, erect, 5-15 cm. long, to 1 cm. wide in anthesis, many-flowered; peduncles short, puberulent; rachis often slightly flexuous, minutely puberulent; flowers somewhat divaricate in anthesis, closely appressed to the rachis in bud and fruit, overlapping; bractlets lanceolate-subulate, 4-6 mm. long, puberulent; pedicels 1 mm. long or less; calyx narrow-tubular, slightly curved, thin-textured, 5-7.5 mm. long, 1.25 mm. wide, very minutely appressed-puberulent, slightly plicate, translucent between the 5 ribs, the rim unequally 5-mucronulate; corolla salverform, pink or rose to lavender, purple or blue, the tube 8.5-10 mm. long, 1.2 mm. wide, glabrous, lobes 1-2.5 mm. long. Fields, clearings, waste places and roadsides, Val Verde Co., Mar.-Nov.; also Ariz., Less. Ant. and Mex. to Col.

2. *Bouchea spathulata* Torr. SPOON-LEAF. Densely branching low shrub, to 6 dm. tall; branches rather stout, subterete, densely pubescent, internodes extremely abbreviated; leaves opposite or ternate, usually densely clustered with 2 or 3 in a cluster and the clusters whorled, sessile or subsessile, fleshy, usually uniformly colored on both surfaces, spatulate, 5-25 mm. long, 2-6 mm. wide, rounded to an acute or obtuse apex, entire, long-attenuate at the base, short-pubescent on both surfaces, often decidedly rugose and nigrescent in drying; spikes 4.5-10 cm. long, 1.5-2 cm. wide, very densely many-flowered, conspicuously bracteate; flowers and fruit ternate, closely overlapping, somewhat divaricate; peduncles none; bracts spatulate, foliaceous, very abundant and conspicuous, 6-10 mm. long, 2-4 mm. wide, lightly pubescent or puberulent; calyx 8-14 mm. long, 2-2.5 mm. wide, very thin-textured between the 5 ribs, scabrous-pubescent, the upper part and lobes usually bright-purple during and after anthesis, rim unequally 5-toothed; corolla large, salverform, lavender, the tube 17-19 mm. long, glabrous, lobes 5 mm. long. Canyons, dry rocky ridges and mt. sides, Brewster Co., June-Oct.; also n. Mex.

3. *Bouchea linifolia* Gray. Low and shrubby, less than 1 m. tall; branches slender, very numerous, erect, conspicuously ridged, glabrate; leaves opposite, numerous, sessile, linear to narrow-lanceolate, 7-44 mm. long, 1.5-4 mm. wide, acute and submucronate, entire, often revolute in drying, narrowed to base, glabrate on both surfaces; spikes 5-12 cm. long, 7-15 mm. wide (or wider during full anthesis), erect, loosely flowered; peduncles very short or obsolete; rachis slender, ridged, glabrate, occasionally purplish at apex; flowers spreading during anthesis, closely appressed to the rachis in bud and fruit; bractlets setaceous-subulate, 1-2 mm. long, usually with 2 smaller ones in the axils; pedicels often subobsolete in anthesis, to 2 mm. long in fruit; calyx slightly curved, 10-13 mm. long, often purplish, glabrous, the rim unequally 5- or 6-toothed; corolla large, lavender, salverform, the tube almost sigmoid, 15 mm. long, glabrous, lobes 6-7 mm. long. Dry calcareous hillside and shrub-covered valleys, from Presidio to Sutton and Uvalde cos., July-Oct.; also N.M.(?) and Coah.

8. PRIVA ADANS.

A genus of about 21 species and 4 named varieties of tropical and subtropical Asia, Asia Minor, Africa and America.

1. *Priva lappulacea* (L.) Pers. COMMON VELVET-BUR, CADILLO DE BOLSA, BUR-VERVAIN, CAT'S-TONGUE, PEGAJOSA, GLOBITO, MOZOTE DE GALLINA, MOZOTE DE POLLO, COLA DE ALACRÁN. Perennial to 1 m. tall, usually lower; stems and branches often prostrate or ascending, pilose with curved or uncinete hairs, in age glabrescent below; petioles 8-30 mm. long, scattered whitish-pilose; leaf blades very thin, ovate, 1.4-14.5 cm. long, 9-85 mm. wide, acute or acuminate, rather uniformly and coarsely serrate (except at base and on terminal acumination) with acute or blunt appressed teeth, mostly subtruncate or subcordate at base (or acute when young) and short-cuneate into the petiole, pilose or strigose above with scattered whitish bulbous-based hairs, scattered-pilose and puberulent beneath, venation inconspicuous; inflorescence 4.5-21 cm. long, 5-15 mm. wide, many-flowered, flowers loosely alternate on a puberulent-pilose rachis; peduncles 8-58 mm. long, puberulent-pilose; bractlets usually surpassing the pedicels; calyx oblong-campanulate, 2-3.1 mm. long, 2.3 mm. wide, densely short-tomentose with short uncinete hairs and with scattered longer straight hairs, minutely 5-apiculate; corolla blue to pink, lavender, purple or white, the tube 3.6 mm. long, lobes broadly elliptic, rounded; pistil compound; fruiting calyx inflated, short-beaked, densely uncinete-hispidulous; cocci glabrous, dorsal surface with 2 parallel rows of straight short spines. Fields, thickets, resacas and roadsides, Cameron Co., throughout year; a cosmopolitan weed in the trop. and subtrop. of the New World; naturalized in Java.

9. CITHAREXYLUM B. JUSS.

FIDDLEWOOD

Shrubs (ours), trees in tropics; branches and branchlets tetragonal, sometimes spiny; leaf scars mostly large, corky and elevated; leaves opposite or whorled, deciduous, exstipulate, entire or dentate, usually bearing a pair of prominent glands at base of blade; inflorescence centripetal, spicate or racemiform, axillary and terminal, mostly elongate and many-flowered, rarely reduced to only a few flowers, erect or nutant, mostly simple, occasionally sparsely branched; flowers small, each subtended by a tiny inconspicuous bractlet; calyx tubular or cyathiform, thin, accrescent, its rim truncate or 5-toothed or -lobed; corolla funnel- or salverform, mostly yellow or white, its tube narrow-cylindric, regular, the limb spreading, 5-parted, with broad slightly irregular lobes, the 2 hindermost outermost in prefloration, mostly more or less pubescent in the throat; stamens 4, didynamous, inserted at or above the middle of the corolla tube, included, a fifth one represented by a very rudimentary staminode; filaments very short; anthers ovate or sagittate, introrse, erect, with 2 parallel thecae opening by longitudinal slits and a thickened connective that often surpasses the thecae in length; style terminal, included, often thickened toward the apex; stigma very shortly bifid; ovary perfectly or imperfectly 4-celled, composed of 2 carpels, each cell with 1 lateral anatropous ovule; fruiting calyx conspicuously enlarged, indurated, cupuliform or patelliform, shorter than the fruit; fruit drupaceous, with juicy exocarp and hard endocarp, with two 2-celled and 2-seeded pyrenes that are often separated by a median fissure.

A genus of about 109 living species, 18 named varieties, 3 hybrids and 4 fossil representatives, from Bermuda and southern United States through the West Indies, Mexico, and Central America to Uruguay and Argentina; several are extensively cultivated.

1. Leaves large, lanceolate to broadly elliptic or ovate to oblong or rhomboid, to 72 mm. long and 45 mm. wide, petiolate 1. *C. Berlandieri*.
1. Leaves small, oblanceolate or spatulate, 2-15 mm. long, 1-4 mm. wide, sessile (2)
- 2(1). Leaves densely short-pubescent 2. *C. brachyanthum*.
2. Leaves glabrous 3. *C. spathulatum*.

1. *Citharexylum Berlandieri* Robins. NEGRITO, ORCAJUELA, ENCORBA GALLINA. Shrub or tree to 6 m. tall; branches heavy, gray, subterete, glabrous, often gnarled; branchlets

more slender, tetragonal, gray-puberulent or glabrate, youngest parts densely short-pubescent or brownish-velutinous; petioles 1-10 mm. long, short-pubescent; leaf blades often firm, lanceolate or oblong to elliptic or ovate, sometimes rhomboid, 14-72 mm. long, 7-45 mm. wide, blunt or acute, entire or with 2 or 3 coarse blunt lobelike teeth near apex, rounded or acute to short-attenuate at base, not glanduliferous, softly short-pubescent above (sometimes only on the larger venation), densely velutinous beneath; racemes 1-8 cm. long, 1-2 cm. wide, densely many-flowered, the terminal one often accompanied by a pair of axillary ones from the uppermost axils; peduncles and rachis densely villous; pedicels to 1 mm. long; calyx 3-4 mm. long, 2-2.5 mm. wide, densely short-pubescent, shortly 5-toothed, ciliolate; corolla white or cream, the tube equaling the calyx, limb 4 mm. wide; fruit red, blackening in drying, 4-5 mm. long and wide, very shiny. Thickets, flats, hillsides and semi-desert roadsides, Hidalgo to Willacy and Cameron cos., Feb.-Aug.; also n. Mex.

2. *Citharexylum brachyanthum* (Gray) Gray. BOXTHORN FIDDLEWOOD, CHILE DE PÁJARO. Shrub to 25 dm. tall, intricately branched, irregular; branches obtusely tetragonal, the angles margined with white or gray corky ridges, glabrous, youngest parts densely short-pubescent, the wood yellow; internodes much-abbreviated; leaves opposite on young shoots, clustered on very short opposite spurlike branchlets on older wood, sessile, oblanceolate or spatulate, often curled in drying, 2-15 mm. long, 1-4 mm. wide, rounded or subacute, entire, cuneate at base, not glanduliferous, densely gray-pubescent on both surfaces; racemes terminating extremely short spurlike branchlets, reduced to 1 or 2 flowers, often borne in pairs at every node of the wood of 1, 2 or even 3 years back; pedicels about 1 mm. long, gray-pubescent; corolla white; fruit pinkish-white when young, red or orange-red when ripe, 5 mm. long and wide, shiny. Mts., plains and dry valley floors, Webb and Zapata cos., June-Sept.; also n. Mex.

3. *Citharexylum spatulatum* Moldenke & Lundell. MISSION FIDDLEWOOD. Slender shrub to 18 dm. tall, diffusely branched; branches long, slender, flexible, glabrous, youngest parts short-hirtellous at the nodes; leaves opposite on young shoots, clustered on short spurlike branchlets on older wood, sessile, spatulate, 8-25 mm. long, 2.5-5 mm. wide, usually rounded, sometimes shallowly emarginate to subacute or apiculate, entire, attenuate at base, glabrous or with a few short stiff hairs at apex; flowers 1 or 2 terminating the spurlike branchlets; pedicels very short, densely white-hirtellous; corolla white, 6 mm. long, lobes rounded, ciliate; fruit orange-red, 6-7 mm. long and wide. *C. brachyanthum* var. *glabrum* Hitchc. & Moldenke. Chaparral, Hidalgo and Starr cos., Apr.-June; endemic.

10. DURANTA L. GOLDEN-DEWDROP

A genus of 34 living species, 14 named varieties, and 1 known fossil representative, of tropical and subtropical America.

1. Corolla purple or lavender to lilac or blue 1. *D. repens*.
 1. Corolla white 1. *D. repens* var. *alba*.

1. *Duranta repens* L. ADONIS MORADO, CELOSA CIMARRONA, CORALILLO, ROSADO, CUENTA DE ORO, ESPINA DE PALOMA, FRUTA DE IGUANA, GARBANCILLO, HELIOTROPIO MORADO, PIGEONBERRY, VARITA DE SAN JOSÉ, YELLOW-HAT-TREE. Extremely variable and polymorphic shrub or small tree, to 6 m. tall; branches slender, often drooping or trailing, unarmed or spiny; leaves numerous, ovate-elliptic or oval to obovate, 1.5-5 cm. long, obtuse to acuminate or apiculate, entire or serrate above the middle, cuneate into a short petiole, glabrate on both surfaces; racemes terminal and axillary, 5-15 cm. long, loosely many-flowered, erect or usually recurved, often paniculate; bractlets minute, occasionally subfoliaceous; pedicels 1-5 mm. long; calyx tubular, 3-4 mm. long, angled, its teeth triangular, subulate, shorter than the tube; corolla blue or lilac to lavender or purple, the tube surpassing the calyx, limb 7-9 mm. wide; fruit yellow, globular, 7-11 mm. long and wide, completely enclosed by the accrescent yellowish mature calyx that is extended into a curved beak. *D. erecta* L., *D. Plumieri* Jacq. Widely cult., tending to escape in Rio Grande Plains and Valley; introd. from W.I.; widespread throughout subtrop. and trop. Am., also introd. in Old World tropics.—var. *alba* (Mast.) Bailey differs in its white corollas; cult., Rio Grande Plains and Valley; nat. to W.I.

11. CALLICARPA L. BEAUTYBERRY

A complex genus of 147 species, 54 named forms and varieties, and 1 known hybrid, widely distributed in subtropical and tropical America, Asia and Oceanica, a few species extending into temperate portions of Asia and the southeastern United States; 1 in Madagascar; several are widely cultivated and tend to escape.

1. Fruit blue or pink to lilac, violet or purple 1. *C. americana*.
 1. Fruit white 1. *C. americana* var. *lactea*.

1. *Callicarpa americana* L. AMERICAN BEAUTYBERRY, FRENCH-MULBERRY, BERMUDA-MULBERRY, SOUR-BUSH, BUNCHBERRY, FILIGRANA, FILIGRANA DE MAZORCA, FILIGRANA DE PIÑAR, FOXBERRY, PURPLE BEAUTYBERRY, SPANISH-MULBERRY, TURKEYBERRY. Bush or shrub to 3 m. tall, usually much-branched; branches densely stellate-scurfy; leaves opposite or ternate; petioles to 38 mm. long, stellate-scurfy; leaf blades very thin, ovate to elliptic, 8-23 cm. long, 3.5-13 cm. wide, acute or acuminate, coarsely serrate or crenate-dentate except at base and apex, cuneately narrowed into the petiole, stellate-scurfy with whitish tomentum (especially beneath and when immature); cymes 1-3.5 cm. long and wide, many-flowered, usually shorter than the petiole, many times dichotomous; peduncles 3-10 mm. long, stellate-scurfy or glabrate; pedicels 0.4-1.2 mm. long, scurfy or glabrate; bractlets subulate or setaceous; calyx obconic or campanulate, 1.6-1.8 mm. long, 1-1.5 mm. wide, slightly puberulent-granulose, rim subtruncate, very shortly apiculate; corolla small, bluish, pinkish, reddish or white, funnelliform, the tube 2.6-2.9 mm. long, lobes about 1.5 mm. long and 1 mm. wide; fruit showy, rose-pink or lilac to violet or red-purple, globose, 3-6 mm. long and wide. Woods, moist thickets, wet slopes, low rich bottomlands, fencerows and the edges of swamps, from Bowie and Grayson to Orange, Jefferson and Goliad cos. w. to Bexar, Kendall and Tarrant cos., June-Dec.; also Md. to Fla. and La., Berm., Cuba and Coah.; also widely cult.—var *lactea* F. J. Mull. differs in having the mature fruit white; sandy open woods, e. Tex.; also N.C. to Fla. and Ark.; sometimes cult.

12. VITEX L. CHASTE-TREE

Trees or shrubs, rarely scandent; leaves opposite, palmately compound, 3- to 7-foliolate (rarely 1-foliolate); leaflets sessile or petiolulate, entire or dentate to incised or lobed; inflorescence determinate, cymose, the cymes short and dense or loosely divaricate, sessile or pedunculate in the leaf axils or aggregate in terminal racemiform or thyrsoid or laxly diffuse panicles, more rarely contracted into heads; flowers perfect, more or less zygomorphic; bractlets usually very small, mostly linear, sometimes surpassing the calyx; calyx campanulate or rarely tubular-infundibular, 5-dentate or -fid, rarely 3-fid, the teeth mostly slightly unequal; corolla white, blue, violet or yellowish, salverform or funnelliform, its tube short or rarely elongate, cylindrical, straight or slightly incurved, equal in diameter throughout or slightly ampliate above, the limb oblique, spreading, sub-bilabiate, the upper lip bifid, the lower lip trifid, the 2 posterior lobes exterior and usually shorter; stamens 4, didynamous, inserted in the corolla tube, often exerted; anthers 2-celled, thecae distinct, subparallel or divergent to arcuate, attached near the apex, dehiscing by longitudinal slits; pistil single, compound, bicarpellary; style terminal, filiform, shortly bifid at apex, branches acute; ovary at first imperfectly 2-celled, later usually 4-celled, cells 1-ovulate; ovules attached laterally at or above the middle of the cell; fruiting calyx often accrescent, usually patelliform or very shallowly cupuliform, rarely subincluding the fruit; fruit drupaceous, more or less fleshy, the endocarp hard, 4-celled; seeds without endosperm.

A genus of about 263 living species, 108 named forms and varieties, and 3 known fossil representatives, mostly of the tropics and subtropics of both the Old and New Worlds; a few also in the temperate portions of Europe and Asia; widely cultivated and naturalized elsewhere.

1. Leaflets mostly 5 to 9, usually entire or undulate-subrepand; cymules usually practically sessile, mostly not conspicuously branched (2)
 1. Leaflets 3 or 5, more or less irregularly dentate, serrate, incised or pinnatisect; cymules distinctly stipitate and conspicuously branched (4)

- 2(1). Corolla white 1. *V. Agnus-castus* f. *alba*.
- 2. Corolla not white (3)
- 3(2). Corolla lavender or lilac 1. *V. Agnus-castus*.
- 3. Corolla blue 1. *V. Agnus-castus* var. *caerulea*.
- 4(1). Leaflets more or less irregularly dentate or serrate with sparse teeth, not incised nor pinnatisect 2. *V. Negundo* var. *intermedia*.
- 4. Leaflets deeply and irregularly incised or pinnatisect . . 2. *V. Negundo* var. *heterophylla*.

1. *Vitex Agnus-castus* L. COMMON CHASTE-TREE, INDIAN-SPICE, HEMP-TREE, MONK'S-PEPPER-TREE, WILD-PEPPER, ABRAHAM'S BALM, CHASTE LAMB-TREE, SAGE-TREE. Shrub or low tree to 5 m. tall; branches densely short-puberulent, resinous-punctate; leaves 5- to 9- (rarely 3-) foliolate; petioles to 75 mm. long, densely puberulent and resinous; leaflets unequal, only the 3 largest ones petiolulate, elliptic, to 11.5 cm. long and 2 cm. wide, attenuate or acuminate at both ends, pulverulent or glabrate above, densely white-puberulent or tomentellous beneath, entire or undulate-subrepand; inflorescence pyramidal-paniculate, terminal and axillary or supra-axillary, to 31 cm. long and 33 mm. wide; cymules numerous, paired, many-flowered, sessile or subsessile; peduncles and rachis densely white-puberulent and resinous-granular, the former 1.5-8 cm. long; pedicels to 1 mm. long; bractlets 1-4 mm. long, linear-setaceous; calyx broadly campanulate, 2-2.5 mm. long, densely white-puberulent, rim shortly 5-toothed; corolla lavender or lilac, the tube 6-7 mm. long, densely white-puberulent above the calyx outside, limb to 13 mm. wide. Widely cult., escaped in every part of Tex. except Trans-Pecos and Plains Country, Apr.-Oct.; introd. from s. Eu. and Orient; very widely cult.; naturalized in various parts of s. U.S.—f. *alba* (West.) Rehd. differs in having white corollas; escaped in n.e. and cen. Tex.—var. *caerulea* Rehd. differs in its blue corollas; escaped in Dallas Co.

2. *Vitex Negundo* L. var. *intermedia* (P'ei) Moldenke. Shrub or tree to 4 m. tall; branches rather densely short-pubescent or puberulent; leaves 3- or 5-foliolate; petioles to 6 cm. long, densely puberulent; leaflets subequal or the 2 lowermost somewhat smaller, all petiolulate, oblong or elliptic to lanceolate, to 11 cm. long and 4 cm. wide, acutely attenuate or subacuminate, irregularly dentate or serrate with sparse scattered teeth, acute or short-acuminate at base, minutely puberulent or glabrous above, appressed-puberulent beneath, often obscurely so in age; inflorescence paniculate, simple or widely branched and thyrsoid, to 42 cm. long and 15 cm. wide, composed of numerous pairs of opposite distinctly stipitate cymes, canescent throughout; bractlets linear, numerous, 2-8 mm. long; peduncles and rachis brown, densely white-puberulent, the former 4.5-7 cm. long; calyx broadly campanulate, 2-3 mm. long, densely white-puberulent, rim 5-toothed with long-apiculate teeth; corolla violet or purple to bluish, the tube 3 mm. long, limb to 7 mm. wide. Sometimes cult., escaped in s. and s.e. Tex.; introd. from China; cult. in many parts of the Old and New Worlds.—var. *heterophylla* (Franch.) Rehd. differs in its usually much smaller leaflets (mostly 2-7 cm. long) that are deeply and very irregularly incised or pinnatisect, the sinuses extending half way to the midrib. Incl. var. *incisa* (Lam.) Clarke. Introd. from China, often cult.; escaped in Brazos Co.

13. CLERODENDRUM BURM.

GLORY-BOWER

Trees, shrubs or woody vines, usually unarmed or rarely with petiole base spinescent; leaves simple, opposite or whorled, deciduous, exstipulate; inflorescence determinate, cymose; cymes mostly rather loose-flowered, more rarely dense, pedunculate in upper leaf axils or paniculate at apex of branchlets, sometimes densely aggregate in terminal corymbs or heads; flowers rather zygomorphic, often large and showy, mostly white, blue, violet or red; calyx often the same color as the corolla or contrastingly red, white or green, campanulate or tubular, truncate to 5-toothed or -fid, often accrescent, subtending the fruit in patelliform fashion or enclosing it; corolla salverform, gamopetalous, its tube

narrow-cylindric, straight or incurved, sometimes ampliate above, often very elongate, more rarely only slightly surpassing the calyx, the limb spreading or subreflexed, 5-parted, lobes subequal or the 2 posterior and exterior ones slightly shorter; stamens 4, didynamous, inserted in the corolla tube, long-exserted, involute in bud, alternate with the corolla lobes; anthers ovate or oblong, 2-celled, with parallel thecae, opening by longitudinal slits; pistil compound, 2-carpellary; style terminal, elongate, shortly and acutely 2-fid at apex; ovary imperfectly 4-celled, each cell 1-ovulate; ovules high-lateral, hemianatropous; fruit drupaceous, globose or obovoid, often 4-sulcate or almost 4-lobed, the exocarp rather fleshy, the endocarp bony, separating into 4 pyrenes or these sometimes cohering in pairs; seeds oblong, without endosperm.

A large and complex genus of about 409 living species, 148 named forms and varieties, and 3 fossil representatives, of tropical and subtropical regions, most abundant in Asia and Africa, poorly represented in America except in cultivation and by naturalization; a few species extending into the temperate zones.

1. Leaves always opposite, deltoid-ovate, very broad, cordate at base, coarsely serrate; corolla short, its tube 2-2.5 cm. long, red or purple . . . 1. *C. Bungei*.
1. Leaves mostly approximate or whorled, narrowly oblanceolate to oblong or elliptic, acute at base; corolla long, its tube 10-14 cm. long, white or yellow 2. *C. indicum*.

1. *Clerodendrum Bungei* Steud. ROSE GLORY-BOWER, BROCAMELIA, CAMELIA AMERICANA, FLOR DE LA ROSA MUERTE, HORTENSIA, VOLCANA. Shrub or tree to 2 m. tall; branches rather stout, shiny, the young parts sparsely pilose-puberulent, soon glabrescent, with numerous whitish elevated lenticels; leaves opposite, strong-scented; petioles stout, to 16.5 cm. long, minutely puberulent or glabrate, usually collapsing at base in drying; leaf blades deltoid-ovate, 6.5-23 cm. long, 4.5-23 cm. wide, acute or short-acuminate, uniformly serrate with broadly triangular apiculate teeth, subtruncate or cordate at base, often slightly short-cuneate into the petiole, pulverulent and scattered-strigillose on both surfaces, becoming almost glabrous, usually with some discoid glands at base beneath; inflorescence terminal, rarely also supra-axillary, paniculate, 6-11 cm. long and slightly wider, densely many-flowered, puberulent throughout; peduncles obsolete or to 1 dm. long; pedicels 1-4 mm. long, densely puberulent; bracts often large and leaflike; bractlets linear-setaceous, 1-3 mm. long, puberulent; calyx campanulate, 3-6 mm. long, minutely puberulent and granular-lepidote, rim with 5 long-acuminate teeth; corolla rose or red to purplish, its tube 2-2.5 cm. long, limb 1-1.4 cm. wide. *C. foetidum* Bunge. Cult. and escaped in Harris Co.: nat. to China and n. India; widely cult. in many parts of the world, naturalized in the Gulf States, P.R., Mex. and S.A.

2. *Clerodendrum indicum* (L.) O. Ktze. TURK'S-TURBAN, TURK'S HEAD, BEADFLOWER, TUBEFLOWER. Virgate shrub or low tree to 2 m. tall; branches very stout, hollow, subglabrous, the larger ones 8- to 10-sulcate; leaves approximate, opposite or whorled in threes to sixes; petioles 4-8 mm. long, glabrous, often striate; leaf blades oblong or elliptic to oblanceolate, 8.5-23 cm. long, 23-55 mm. wide, acute or acuminate, entire, acute at base, glabrous on both surfaces, sparsely punctate beneath; inflorescence axillary and terminal, abundant; cymes usually supra-axillary, 4-6 cm. long, few-flowered, lax, widely divaricate; terminal panicle thyrsoid, to 45 cm. long or longer and 25 cm. wide, very showy, composed of 3 to 12 whorls of cymes, glabrous; bractlets broadly linear, very numerous, 5-15 mm. long, 2-3 mm. wide, glabrous; calyx very broadly campanulate, thick, its tube 5-7 mm. long, the rim deeply 5-lobed, lobes wide-spreading, ovate, 6-10 mm. long and almost as wide, acute or subacute, glabrous; corolla white to yellow, very large, the slender tube 10-14 cm. long, glabrous, limb 1.5-2 cm. wide. *Siphonanthus indica* L. In cult. and tending to escape in Harris Co.; introd. from India and Burma; widely cult. in many parts of the world; naturalized in the Gulf States, W.I. and n. S.A.

14. TETRACLEA GRAY

Low erect annual or perennial herbs or subshrubs, woody at base; leaves simple, opposite, deciduous, oblong or ovate, dentate or entire, those in the inflorescence similar but smaller; inflorescence axillary, determinate, cymose, pedunculate, mostly 1- to 3-

flowered; flowers short-pedicellate; calyx broadly campanulate, 8- or 10-veined, deeply 4- or 5-parted, persistent, accrescent, the lobes subequal; corolla gamopetalous, salverform, white or tinged with red, its tube exerted, narrow-cylindric, limb spreading, 5-parted, lobes obovate-oblong, subequal; stamens 4, didynamous, long-exserted, incurved-ascending, the anterior pair longer; anthers 2-celled, the thecae distinctly parallel; disk present, equal, short; ovary shortly 4-lobed at apex; style bifid at apex, the branches subulate and subequal; pyrenes obovoid, hard, reticulate-rugose, attached to beyond the middle by a broad keeled areole, the fallen ones not leaving a gynobase; seeds attached laterally.

A genus of only 2 known species and 1 variety of southwestern United States and Mexico. Included in the Labiatae by some authors.

1. Annual, the pubescence sticky-glandular; leaves elliptic, sessile or nearly so 1. *T. viscida*.
1. Perennial, the pubescence not glandular; leaves oblong or ovate, plainly petiolate (2)
- 2(1). Leaf blades broadly ovate, at least the lower ones entire 2. *T. Coulteri*.
2. Leaf blades narrowly oblong, conspicuously toothed . . . 2. *T. Coulteri* var. *angustifolia*.

1. *Tetraclea viscida* Lundell. Erect viscid annual to 45 cm. tall, densely puberulent with gland-tipped hairs; stem and main branches drying reddish-purple; branchlets green, subterete; leaves sessile or subsessile (with petioles not over 3 mm. long), thick and fleshy, narrowly elliptic, 5-18 mm. long, to 9 mm. wide, acute at both ends, broadest at the middle, glandular-puberulent on both surfaces with some coarser eglandular incurved hairs intermixed; cymes 1- or 2-flowered; peduncles to 1 cm. long; pedicels to 1 mm. long; calyx campanulate, 8- or 10-veined, 4- or 5-lobed, to 8 mm. long in fruit and lobed to below the middle; corolla less than 5 mm. long, the 4 outer lobes pubescent above the middle outside, the other lobe with a line of hairs on the midvein. Known only from Uvalde Co., Sept.; also in cen. Ariz.

2. *Tetraclea Coulteri* Gray. Herbaceous perennial; stems ascending or spreading, branching, from a woody base, to 4 dm. tall; branches very slender, gray, densely whitish appressed-puberulent, not glandular; petioles 4-10 mm. long, appressed-puberulent; leaf blades ovate, 16-35 mm. long, 6-18 mm. wide, sharply acute and mucronulate, irregularly dentate with 2 or 3 teeth on each margin or at least the lower ones entire, acute or acuminate at base and prolonged into the petiole, finely substrigose-puberulent on both surfaces with whitish hairs, not glandular; cymes mostly 3-flowered, sometimes reduced to 1 or 2; peduncles 3-8 mm. long; corolla cream-colored, tinged with red outside, lobes elliptic-obovate, entire. Foothills, riverbeds, chaparral and sandy flats, South Plains, Trans-Pecos and Rio Grande Plains, Mar.-Sept.; also in Ariz., N.M. and Mex.—var. *angustifolia* (Woot. & Standl.) A. Nels. & Macbr. differs in having its leaf blades narrowly oblong and always very conspicuously toothed, the stems taller and more slender, less pubescent with shorter hairs, the calyx lobes narrower, and the pyrenes more reticulated; in depressions, on banks and on dry rocky plains in the South Plains and Trans-Pecos; also N.M., Ariz. and Mex.

FAM. 158. LABIATAE JUSS.

MINT FAMILY

Plants herbaceous annuals or perennials with spreading rhizomes, occasionally woody shrubs; stems typically square; leaves opposite; flowers variously arranged; calyx usually more or less 2-lipped, the upper 3 teeth more or less joined, the lower pair of teeth usually free, occasionally all teeth subequal, the tube mostly enlarged in fruit; corolla obscurely to distinctly 2-lipped, the upper 2 petals usually joined to form an erect sometimes galeate lip that includes the stamens or sometimes very short and deeply notched, occasionally with the 5 lobes subequal, the lower lip usually spreading with its midlobe sometimes dipperlike; stamens 2 or 4, mostly in 2 unequal pairs, the connective sometimes strongly developed at the expense of the filament; anthers parallel or divergent, with one cell sometimes completely or partly aborted; style bifid at apex, arising between

the quite distinct lobes of the 4-lobed ovary or from near the apex of the ovary when the lobes (and the cocci) are partly united below.

A large family of about 3,500 species in 180 genera of world-wide distribution. The typically aromatic plants provide many herbs used as condiments. The family contains numerous important honey plants.

Rosmarinus officinalis L. (ROSEMARY), an aromatic evergreen Mediterranean shrub often cultivated in south Texas, is occasionally found as a possible escape. The shrub grows to 2 meters high and may be distinguished by its thick, narrowly linear, entire, revolute leaves (15-25 mm. long) that are lustrous dark-green above and white-tomentose beneath. The violet-blue flowers, in axillary racemes, are about 1 cm. long and have only 2 perfect stamens.

1. Ovary 4-lobed; style not basal; cocci almost completely united, laterally or obliquely attached (2)
1. Ovary of 4 distinct or nearly distinct cocci; style basal; cocci essentially free, basally attached (4)
- 2(1). Corolla nearly regular, distinctly 2-lipped 1. *Trichostema*, p. 1345.
2. Corolla strongly irregular so as to appear 1-lipped (3)
- 3(2). Leaves of flowering stems entire or indistinctly and bluntly toothed 2. *Ajuga*, p. 1346.
3. Leaves of flowering stems sharply to coarsely toothed or deeply lobed 3. *Teucrium*, p. 1347.
- 4(1). Calyx 2-lipped, the lips entire (5)
4. Calyx regularly 5- (rarely 10-) toothed or 2-lipped with 3 teeth on the upper lip and 2 teeth on the lower lip (6)
- 5(4). Calyx bladderly-inflated in fruit; flowers in loose spikes; rare desert shrub 4. *Salazaria*, p. 1348.
5. Calyx with helmetlike protuberance on the upper side; flowers solitary in the axils; widespread herbs and subshrubs 5. *Scutellaria*, p. 1349.
- 6(4). Stamens declined toward or resting on the lower lip of the corolla, 2 long and 2 short; corolla declined, the upper lip with 4 entire lobes, the lower lip saccate and abruptly deflexed at the contracted and callous base 6. *Hyptis*, p. 1354.
6. Stamens not declined and resting on the lower lip of the corolla (7)
- 7(6). Stamens and style included in the tube of the small corolla; plant villous or woolly-villous (8)
7. Stamens and style mostly exerted beyond the corolla tube; plant rarely woolly (9)
- 8(7). Calyx teeth 10, clawlike; corolla white; leaves prominently rugose-veined 7. *Marrubium*, p. 1354.
8. Calyx teeth 5, not clawlike; lower lip of corolla dark-purple; leaves not noticeably rugose 8. *Sideritis*, p. 1354.
- 9(7). Fertile stamens 4, all with 2-celled anthers; upper lip of corolla galeate or concave (10)
9. Fertile stamens 2 or (if 4) the upper pair shorter than the lower pair and the upper corolla lip neither galeate nor concave (19)
- 10(9). Calyx enlarging into a flaring veiny funnel about 25 mm. across; floral bracts stoutly spinose 9. *Molucella*, p. 1355.
10. Calyx not as above; floral bracts not stoutly spinose (11)
- 11(10). Upper pair of filaments longer than the lower pair (12)
11. Upper pair of filaments shorter than the lower pair (except in *Leonurus*) (13)
- 12(11). Anther sacs parallel or nearly so 10. *Agastache*, p. 1355.
12. Anther sacs divergent 11. *Nepeta*, p. 1356.
- 13(11). Calyx strongly 2-lipped (14)
13. Calyx not 2-lipped, the lobes essentially similar (15)

- 14(13). Anther sacs divaricate; flowers 3 together or 6 in a whorl; calyx dorsally flattened 12. *Prunella*, p. 1357.
14. Anther sacs parallel; flowers solitary or 2 together; calyx somewhat inflated 13. *Brazoria*, p. 1357.
- 15(13). Tube of the calyx faintly nerved, inflated at maturity 14. *Physostegia*, p. 1359.
15. Tube of calyx prominently 5- or 10-nerved, not inflated at maturity (16)
- 16(15). Cocci nearly terete, rounded at apex 15. *Stachys*, p. 1361.
16. Cocci 3-sided, truncate at apex (17)
- 17(16). Calyx lobes not spine-tipped 16. *Lamium*, p. 1363.
17. Calyx lobes spine-tipped (18)
- 18(17). Calyx lobes 5 17. *Leonurus*, p. 1363.
18. Calyx lobes 8 to 10 18. *Leonotis*, p. 1363.
- 19(9). Functional stamens 2, ascending and parallel, the upper pair wanting or rudimentary; anthers mostly appearing to be 1-celled; corolla strongly 2-lipped (20)
19. Functional stamens 2 or (if 4) with the upper pair shorter than the lower pair; anthers always 2-celled; corolla scarcely 2-lipped, the upper lip neither galeate nor curved (22)
- 20(19). Connective of the anther elongated, usually but not always bearing a perfect sac at one end and a rudimentary sac at the other end, very rarely 2-celled 19. *Salvia*, p. 1364.
20. Connective of the anther short; anther sacs confluent (21)
- 21(20). Calyx elongate-tubular, nearly regular, with 5 subequal teeth; midlobe of lower lip of corolla larger or longer than the lateral lobes .. 20. *Monarda*, p. 1370.
21. Calyx ovoid-tubular, 2-lipped, with subulate or bristlelike teeth; midlobe of lower lip of corolla narrower than the rounded lateral lobes 21. *Blephilia*, p. 1375.
- 22(19). Flowers in loose terminal racemes or panicles, slender-pedicelled 22. *Perilla*, p. 1376.
22. Flowers in axillary whorls or clusters that sometimes form terminal spikelike racemes or panicles (23)
- 23(22). Corolla regular or essentially so, with 4 or 5 equal lobes (24)
23. Corolla more or less 2-lipped; upper corolla lip erect, entire or emarginate (25)
- 24(23). Fertile stamens 2; flowers white, clustered in the axils of reduced upper leaves; foliage scarcely aromatic 23. *Lycopus*, p. 1376.
24. Fertile stamens 4; flowers purplish to bluish or white, spicate or clustered in upper axils; foliage strongly aromatic 24. *Mentha*, p. 1377.
- 25(23). Stamens ascending or arched, commonly converging or ascending parallel under upper lip of corolla (26)
25. Stamens distant and straight, often spreading-divergent, never connivent or curved (30)
- 26(25). Fertile stamens 2 (27)
26. Fertile stamens 4 (29)
- 27(26). Small shrubs; calyx softly and densely hairy with hairs as long as the calyx teeth; calyx teeth deltoid, undifferentiated, enclosing the calyx tube at maturity .. 25. *Poliomintha*, p. 1378.
27. Perennial herbs; calyx mostly bristly pubescent; calyx teeth differentiated into upper and lower sets, not enclosing the calyx tube at maturity (28)
- 28(27). Calyx gibbous, the throat closed by hairs; corolla without folds in the throat; stamens exerted from corolla tube 26. *Hedeoma*, p. 1379.
28. Calyx not gibbous, the throat not closed by hairs; corolla with 2 folds in the throat; stamens included in the corolla tube 27. *Rhododon*, p. 1383.

- 29(26). Calyx with 5 subequal lobes, scarcely 2-lipped; leaves more or less orbicular ..
28. *Micromeria*, p. 1384.
 29. Calyx distinctly 2-lipped, the lobes unequal; leaves of a linear type
29. *Satureja*, p. 1384.
 30(25). Fertile stamens 430. *Pycnanthemum*, p. 1384.
 30. Fertile stamens 231. *Cunila*, p. 1386.

1. TRICHOSTEMA L.¹⁶⁰

Annuals or suffrutescent perennials; stems variously pubescent; leaves subsessile to petioled, linear to elliptic or ovate, usually entire; inflorescence glandular, the flowers 1 to many in axillary cymes, the lateral branches of which develop racemosely or the entire inflorescence racemose; calyx regular or irregular, the upper 3 teeth fused two-thirds their length in which case the calyx bends backward and becomes resupinate at maturity, the upper lip then appearing as the lower; corollas blue or lavender, often pink or even white, the lowermost normally longest, as much as one and one half times the length of the other 4 equal lobes, pubescent on the outside, glabrous within; stamens 4, usually seated near the throat and ascending, arched or nearly straight, sometimes thrust out between the upper two lobes of the corolla, the anther sacs divergent at maturity; styles about as long as the stamens, the upper branch usually somewhat shorter than the lower; cocci joined one-third their length, alveolate or rugose-reticulate, the ridges varying in prominence.

About 15 species in North America.

1. Calyx regular, the teeth equal or nearly so (2)
1. Calyx 2-lipped, the upper 3 teeth partially fused, the lower pair of teeth free and shorter, the whole calyx becoming inverted (resupinate) at maturity (3)
- 2(1). Plants annual1. *T. brachiatum*.
2. Plants perennial, forming small or large bushes, woody at the base
2. *T. arizonicum*.
- 3(1). Leaves linear, at least 6 times as long as broad ...3. *T. setaceum*.
3. Leaves oval to oblong, not more than 5 times as long as broad
4. *T. dichotomum*.

1. *Trichostema brachiatum* L. FLUX-WEED. Weedy annual herb to 4 dm. tall; stems usually freely branched, hirtellous below the inflorescence with short spreading or downwardly curled but seldom appressed hairs, often pilose with longer straight hairs about 1 mm. long and occasionally and irregularly sprinkled with capitate glands; leaves elliptic to linear, acute at the apex, narrowed at the base to indefinite petioles as much as 1 cm. long, 2-5 cm. long, 4-16 mm. wide, both surfaces hirtellous with short hairs curled toward the apex, usually sprinkled with capitate glands, usually 3-nerved, the margins entire or sometimes irregularly serrate; cymes axillary, predominantly 1-flowered, often 2- to 3-flowered, the peduncles seldom exceeding 2 cm. in length, clothed like the stems but usually more glandular, the small bracts seldom exceeding 3 mm.; flowering calyx regular, the triangular-lanceolate teeth 1.5-3.7 mm. long but increasing to 2.5-4.9 mm. in fruit, the tube shorter than the teeth; corolla rose-pink; corolla tube straight, flaring somewhat at the throat, not exerted from the calyx, 1.6-3.5 mm. long, the lower lip 1.3-2.1 mm. long, usually somewhat longer than the 4 upper lobes; stamens straight or but slightly arched, 2.3-4.2 mm. long, not greatly exerted from the corolla; cocci 2-2.9 mm. long, hirtellous at least at apex with short usually curled hairs and irregularly sprinkled with capitate glands, alveolate, the ridges prominent. *Isanthus brachiatus* (L.) B.S.P. In sandy or limestone soils, mainly on the Edwards Plateau, July-Oct.; from Ont. and N.E., s. to N.C., Ga., Ala., Ark. and Tex.

2. *Trichostema arizonicum* Gray. Suffrutescent perennial, woody at the base, with numerous straight erect herbaceous branches 2-6 dm. long, these hirtellous with short

¹⁶⁰ Adapted from Harlan Lewis in *Brittonia* 5:276-303. 1945.

downwardly curled hairs (particularly on the faces directly above the leaves), occasionally irregularly interspersed with sessile glands; leaves oblong to ovate, 1-3 cm. long, 5-15 mm. wide, frequently with numerous smaller leaves on dwarf branches in the axils, acute to obtuse at the apex, acute or somewhat rounded at the base, sessile or with indefinite petioles as much as 5 mm. long, the margins entire, sometimes irregularly crenate, both surfaces sparsely hirtellous with short hairs curled toward the apex, often with numerous sessile glands; cymes as much as 4 cm. long, 1- to 7-flowered, borne in graceful narrow panicles; flowering calyces hirtellous with short rather stout upwardly curled hairs or these nearly lacking, usually with many sessile or rarely capitate glands, 2.5-4 mm. long, increasing to 3.5-6.5 mm. in fruit, the teeth subequal, lanceolate to nearly deltoid, about the length of the tube; corolla tubes not exerted from the calyx, straight, 2-4 mm. long, the lower lip 5-10 mm. long; stamens strongly arched, 1-2.5 cm. long; cocci 2-3 mm. long, irregularly alveolate, the ridges not prominent, glabrous, sometimes minutely hirtellous at the apex. Rare in Guadalupe Mts. in the Trans-Pecos, summer-fall; Tex., N.M., Ariz. and n. Mex.

3. *Trichostema setaceum* Houtt. Weedy annual herb to 5 dm. tall; stems usually branched, hirtellous below the inflorescence with short downwardly curled hairs, rarely nearly glabrous; leaves linear to narrowly lanceolate, 2-5 cm. long, 1-5 mm. wide, rarely as much as 7 mm. wide, hirtellous with short hairs curled toward the apex, acute at apex, the base narrowed to an indefinite petiole as much as 5 mm. long, the margins entire; cymes axillary, 3- to 7-flowered; the peduncles as much as 5 cm. long, the pedicels about 5 mm. long, both clothed with short stout spreading hairs and glandular-capitate hairs, the bracts often leaflike; calyces strongly zygomorphic, the lower 2 teeth about one third the length of the upper three which are fused for one-half to two-thirds their length; flowering calyces 3.5-5.5 mm. long, becoming inverted at maturity so that the 3 long teeth are lowermost, increasing to 4.5-7.5 mm. long; corolla tube not extending beyond the longer calyx teeth, 2.3-3.8 mm. long, the lower lip 2.8-6 mm. long; stamens exerted, arched, 8-20 mm. long; cocci 1.5-2 mm. long, glabrous, alveolate, the ridges prominent. In dry sandy soil in open woods in e. Tex., July-Oct.; from Conn. and N.Y., s. to Fla. and e. Tex.

Closely allied to *T. dichotomum* but has much narrower leaves.

4. *Trichostema dichotomum* L. FORKED BLUE CURLS, BASTARD PENNY ROYAL. Weedy annual herb as much as 1 m. tall; stems usually branched, hirtellous below the inflorescence with short downwardly curled or straight spreading hairs, usually pilose with longer straight hairs and occasionally sprinkled with capitate glands, rarely only pilose; leaves oblong to ovate, to 6 dm. long and 25 mm. wide, hirtellous with short hairs curled toward the apex, acute to obtuse at apex, the base narrowed to a petiole 2-15 mm. long, the margins entire; cymes axillary, 3- to 7-flowered, the peduncles as much as 5 cm. long, the pedicels about 5 mm. long, both glandular with stalked capitate glands, usually hirtellous with short spreading hairs and having longer coarse hairs 2 to 3 times the length of the glandular hairs or these absent, the bracts often leaflike; calyces strongly zygomorphic, the lower teeth about one third the length of the upper three which are fused for one-half to two-thirds their length; flowering calyces 2.7-6 mm. long, becoming inverted at maturity so that the three long teeth are lowermost, increasing to 4.6-8.9 mm. long; corolla bluish; corolla tube not extending beyond the longer calyx teeth, 1.5-4 mm. long, the lower lip to 7 mm. long; stamens exerted, arched, 6-16 mm. long; cocci 1.5-2.9 mm. long, glabrous, alveolate, the ridges prominent. In sandy soil in open woods and on stream banks in e. Tex., July-Oct.; from N.E., s. to Fla. and Tex.

2. AJUGA L.

About 40 species of wide distribution.

1. *Ajuga reptans* L. BUGLE. Low perennial, spreading by leafy stolons to form mats; flowering stems to 3 dm. high, essentially glabrous; leaves obovate to oblong-spatulate, 2-5 cm. long, the larger ones commonly sinuate-dentate, the lower leaves tapered to a margined petiole, the upper leaves sessile; flowers sessile, in whorls of 2 to 6 in the axils of bracteal leaves to produce a terminal leafy spike; calyx 4-6 mm. long, sparsely villous, the 5 lobes ovate-triangular, somewhat shorter than the tube; corolla blue to purplish, upper lip of corolla very short, bilobed; lower lip of corolla elongate and

dilated, the lateral lobes shorter and narrower than the broad bilobed midlobe; stamens 4, unequal in length, included; ovary shallowly 4-lobed; style terminal. A nat. of Eur. that is cult. as a ground cover and occasionally escapes or persists, Apr.-July.

3. TEUCRIUM L.¹⁶¹

GERMANDER

Perennial herbs to 15 dm. high, with simple serrate leaves and the flowers in terminal slender spikes or smaller annual or perennial plants with at least some of the leaves pinnatifid and with the flowers in the axils of the reduced upper leaves; calyx saccate, toothed or deeply 5-lobed; corolla pinkish to bluish or pallid, the upper lip very short and deeply notched, the lower lip conspicuous and spreading, with small lateral lobes; stamens 4, paired, exerted from the deep cleft between the 2 upper lobes of the corolla; cocci roughened.

About 300 species in temperate and tropical regions of both hemispheres.

1. Leaf blades toothed, pubescent on lower surface; flowers in a terminal bracteate spike; corolla lavender with dark dots 1. *T. canadense*.
1. Leaf blades noticeably lobed (especially the lower ones), glabrous; flowers in the axils of the reduced upper leaves; corolla white with pink to purple markings toward the base (2)
- 2(1). Largest lobes of corolla 5-8 mm. long; leaf blades mostly with a few wide lobes; plant usually more than 2 dm. high 2. *T. cubense*.
2. Largest lobes of corolla 9-13 mm. long; leaf blades laciniately lobed into narrow segments; plant mostly less than 1.5 dm. high 3. *T. laciniatum*.

1. *Teucrium canadense* L. AMERICAN GERMANDER, WOOD SAGE. Perennial herb as much as 1 m. tall, with creeping rootstocks and erect stems that branch chiefly in the inflorescence, the latter usually silvery with closely appressed minute hairs, sometimes pubescent with curled hairs or hirsute with elongate spreading or deflexed glandular or eglandular hairs, rarely glabrate; leaves prevailing 6-10 cm. long and 2-4 cm. broad, narrowly elliptic to oval or ovate, acute to acuminate or rarely obtuse at apex, generally narrowed below the middle but sometimes rounded at the base or even subtruncate, obscurely or strongly toothed, the upper surfaces glabrous or variably pubescent with curled or straight hairs or variably hirsute with elongate stiffish glandular or eglandular hairs, the lower surfaces silvery with minute closely appressed hairs or pubescent with small curled hairs or even tomentose with longer curled hairs or hirsute with glandular spreading hairs, rarely glabrous; median petioles to 15 mm. long; flowers subsessile, disposed in usually dense conspicuously bracteate spikes 2-3 dm. long, the bracts usually exceeding the calyces; flowering calyces 5-7 mm. long, silvery with minute appressed hairs or pubescent with curled and spreading glandular hairs or hirsute with elongate mostly glandular hairs, these variably combined in some forms, the tube enlarged and cuplike at maturity but scarcely saclike or inflated, the orifice oblique; calyx teeth deltoid, the three upper more or less joined and tending to be obtuse or blunt, the two lower more or less acute or acuminate and generally about 2 mm. long; corolla 11-18 mm. long, the tube 4-7 mm. long; cocci glabrous, wrinkled. Incl. var. *virginicum* (L.) Eat., *T. virginicum* L. In water and mud along streams and canals, about lakes, in marshes and wet grassy swales throughout Tex., May-Sept.; a variable species that occurs from Que. to B.C., s. to Cuba and Mex.

The following varieties are found in Texas.

1. Hairs of the stem and lower leaf surface elongate, spreading, dense, more or less glandular; calyx tomentose with short as well as long glandular hairs; confined to the Rio Grande Valley region (*T. occidentale* Gray)
..... var. *occidentale* (Gray) McCl. & Epl.
1. Hairs of stem and lower leaf surface minute, curling and eglandular; calyx mostly thinly pubescent with nonglandular hairs .. var. *canadense*.
2. *Teucrium cubense* Jacq. Annual or perennial weedy herb; stems usually several from a taproot, branching at the base and often above, more or less bushy, as much as

¹⁶¹ Adapted from Elizabeth McClintock and Carl Epling in *Brittonia* 5:491-510. 1946.

7 dm. high, usually much smaller, glabrous or cinereous with minute spreading or downwardly curled hairs, sometimes pubescent in the inflorescence with longer somewhat curled hairs; basal leaves oblong to obovate, shallowly lobed to crenate or entire, attenuate to petioles that are usually shorter than the blades, soon withering, these passing into the cauline leaves that are variably lobed, these (in turn) passing gradually into the leaves of the inflorescence that are sometimes subentire, sometimes lobed to the middle or sometimes lobed nearly to the base with the lobes linear; flowers with slender pedicels 4-12 mm. long, usually in the upper half of the stem, sometimes nearly to the base; flowering calyces campanulate, glabrous or hirtellous with minute spreading hairs and glandular or sometimes pubescent with longer somewhat curled hairs, 5-10 mm. long, the tubes 2-3 mm. long; calyx teeth 3-6 mm. long, deltoid-lanceolate, closed over the cocci at maturity or spreading; corolla white, often with purple lines in throat, pubescent, tending to be bearded in the throat, 7-15 mm. long, the tube 1-2 mm. long, the lower lip 4-8 mm. long; stamens glabrous, the longer pair 6-8 mm. long; cocci pitted or grooved lengthwise (the grooving may be a function of the degree of maturity), glabrous or pubescent at the tip. *Melosma cubense* (Jacq.) Small. In clay or hard sandy loams, along streams and draws, in palm groves and low grassy soils along the coast and Rio Grande Plains, w. to the Trans-Pecos, throughout the year; from s.w. U.S., through W.I. to s. S.A.

The following varieties are found in Texas.

1. Plant annual, pubescent along the stem and in the inflorescence with scattered long coarse somewhat curled hairs; flowers disposed often nearly to the base of the stems; cocci conspicuously pubescent at the apex with a tuft of hairs; confined to the Trans-Pecos [*T. depressum* (Small) McCl. & Epl.] var. *densum* Jeps.
1. Plant annual or perennial, glabrous or sparingly puberulent along the stem and in the inflorescence; flowers chiefly in upper part of stem; cocci with globular glands or rarely minutely pubescent (2)
- 2(1). Median leaves irregularly lobed about halfway to the midrib or only deeply crenate; floral leaves 3-lobed to the middle or entire; along the coast and in the Rio Grande Plains and Valley [subsp. *chamaedriformium* (Mill.) Epl.] var. *cubense*.
2. Median leaves mostly 3- or 5-lobed nearly to the midrib, the lobes linear; floral leaves 3-parted nearly to the base; in the Rio Grande Plains and Trans-Pecos [*T. laevigatum* Vahl, *Melosma laevigatum* (Vahl) Small] subsp. *laevigatum* (Vahl) McCl. & Epl.

3. *Teucrium laciniatum* Torr. Perennial herb usually 7-15 cm. tall, rarely to 25 cm., branching from base, the stems many, erect, tufted, usually unbranched, forming beds from oblique creeping roots, entirely glabrous or occasionally with a few scattered minute spreading hairs; leaves pinnately cut nearly to the midrib into 2 to 8 usually entire but sometimes branched lobes, 15-55 mm. long, the lobes 2-4 mm. wide, blunt or gradually acuminate at the tips, their margins usually inrolled on the lower side, a few of the basal leaves occasionally entire; flowers crowded toward the tips of the branches, sweet-scented with a spicy odor, the pedicels 3-8 mm. long; flowering calyces campanulate, 8-13 mm. long, the tube 2-4 mm. long, the acuminate teeth 5-10 mm. long; corolla white to cream-color or rarely pale-green, usually with purplish veins in throat, glabrous or with a few scattered hairs on the outside, bearing a dense beard of hairs in the throat and a few scattered hairs on the lower lip, 14-22 mm. long, the tube 1-2 mm. long, the lower lip 8-14 mm. long; stamens glabrous or pubescent on the lower half, the longest pair 9-11 mm. long; cocci about 3 mm. long, oval, rugose or grooved lengthwise, glabrous. On limestone and gypseous soils from the Edwards Plateau to the Trans-Pecos and Plains Country, May-Sept.; also Okla., Colo. and N.M.

4. SALAZARIA TORR.

A monotypic genus.

1. *Salazaria mexicana* Torr. BLADDER-SAGE. Shrub to 2 m. high, intricately branched, the branchlets becoming spiny-tipped, pale-green and minutely canescent; leaves short-petioled, ovate to ovate-oblong or the upper ones reduced and narrowly oblong, entire or rarely toothed, to about 25 mm. long, rounded to subcordate at base; flowers subsessile

in the axils of the upper bractlike leaves, forming an open narrow raceme; calyx equally 2-lobed, 6-8 mm. long in flower, the lips entire, becoming inflated into a papery bladder in fruit; corolla bilabiate, pink with a purple lip, 12-18 mm. long, pubescent on the outer surface, the upper lip arched, the lower lip broad with recurved margins and its 2 small lateral lobes attached to the base of the upper lip; stamens 4, in 2 pairs, included in the upper lip; style entire, included; fruiting calyx papery and subglobose, 16-18 mm. long; cocci 4, tuberculate, raised on a gynobase. In chaparral of desert washes and on clay flats in s. Trans-Pecos, July-Nov.; also Mex.

5. SCUTELLARIA L.¹⁶² SKULLCAP

Bitter perennial or annual herbs or subshrubs, commonly rhizomatous, not aromatic; flowers 1 to 3 together on short peduncles or pedicels in the axils or often in 1-sided bracted axillary racemes or terminal spikes or racemes; calyx campanulate in flower, splitting to the base at maturity, strongly bilabiate, the lips entire, the upper longer lip usually falling away, in fruit with an appendage or scale; corolla with an elongated curved ascending tube exerted from the calyx, dilated at the throat, the upper lip entire or barely notched, the lateral lobes mostly connected with the upper rather than the lower lip, the lower spreading lobe or lip convex and notched at the apex; stamens 4, ascending under the upper lip; anthers approximate in pairs, ciliate or bearded, those of the lower stamens 1-celled, those of the upper stamens 2-celled and cordate; cocci variously marked.

About 300 species of wide geographic distribution.

1. Low herbs or subshrubs, mostly less than 3 dm. high; leaves 1-2 cm. long, entire (or crenulate in *S. muriculata*) (2)
1. Rather tall herbs, mostly much more than 3 dm. high; leaves 3 cm. long or more, more or less dentate to crenate or rarely entire (in *S. integrifolia*) (9)
- 2(1). Plant with fibrous roots and moniliform rhizomes; cocci provided with an encircling wing or skirt and covered with peglike processes 1. *S. parvula*.
2. Plant with fibrous roots and often a woody caudex, usually with slender or stout rhizomes; cocci variously covered, not as above (3)
- 3(2). Plants essentially glabrous throughout, at most with scattered sessile glands; endemic to Trans-Pecos Texas 2. *S. laevis*.
3. Plants variously pubescent or glandular-pubescent; mostly east of Trans-Pecos Texas (4)
- 4(3). Calyx with sessile or short-stalked glands or appressed-puberulent, never noticeably long-pubescent (5)
4. Calyx with long conspicuous glandular or nonglandular hairs (7)
- 5(4). Stem puberulent with minute decurved-appressed hairs to give a smooth appearance, without glandular hairs 3. *S. Wrightii*.
5. Stem with spreading glandular or nonglandular hairs (6)
- 6(5). Stem densely puberulent with minute conical glandless hairs; distribution in Plains Country 4. *S. resinosa*.
6. Stem thinly pubescent with soft glandular hairs; distribution southwest Texas 5. *S. microphylla*.
- 7(4). Stem with long spreading usually somewhat glandular hairs; cocci covered with blunt subimbricated scalelike processes 6. *S. Drummondii*.
7. Stem with most or all the hairs retrorse-decurved and glandless; cocci not as above (8)
- 8(7). Cocci covered with sharp conical processes; leaves with noticeably crenulate margins; plant annual; distribution in the Rio Grande Plains and coastal Texas .. 7. *S. muriculata*.
8. Cocci granulose with rounded low tubercles; leaves with entire margins; plant perennial; distribution in Trans-Pecos Texas 8. *S. potosina*.

¹⁶² Adapted from Carl Epling in Univ. Calif. Publ. Bot. 20:1-146. 1942.

- 9(1). Median leaves oblong to linear-lanceolate, entire, tapered at base to a short petiole 9. *S. integrifolia*.
9. Median leaves deltoid-ovate to ovate-oblong, more or less dentate or serrate, broadly cuneate to rounded or cordate at base (10)
- 10(9). Median leaves ovate-oblong; petiole mostly 3 mm. or less long; distribution in Texas Panhandle 10. *S. galericulata*.
10. Median leaves broadly ovate to ovate-lanceolate; petiole usually much more than 5 mm. long; distribution mainly in east Texas (11)
- 11(10). Upper surface of leaves essentially glabrous; lower part of stem essentially glabrous or with minute decurved hairs (12)
11. Upper surface of leaves noticeably pubescent with spreading often glandular hairs (13)
- 12(11). Stems strict and stiffish; calyx and triangular-ovate leaflike bracts subtending the flowers coarsely ciliate on margins; galea and corolla tube 13-22 mm. long 11. *S. cardiophylla*.
12. Stems mostly weak and spreading; calyx and elliptic-lanceolate bracts subtending the flowers essentially glabrous or minutely puberulent; galea and corolla tube 5-7 mm. long 12. *S. lateriflora*.
- 13(11). Floral rachis densely pubescent with glandular spreading hairs, the bracts ovate; median leaves with strongly cordate base 13. *S. ovata*.
13. Floral rachis with curved appressed glandless hairs, the bracts elliptic; median leaves with subtruncate to broadly cuneate base 14. *S. elliptica*.

1. *Scutellaria parvula* Michx. Small herb, 1-3 dm. high, spreading by moniliform rhizomes, the tubers fusiform to ellipsoid and white; stems usually erect, branching at the base, pubescent to glabrate; leaves pilose to glabrate; median leaves sessile, deltoid-ovate to ovate-oblong, usually irregularly subdentate, 8-19 mm. long, 4-12 mm. broad; lowermost leaves with petioles 5-15 mm. long, subrotund 7-12 mm. wide; flowers axillary, mostly above the middle of the plant, borne on retrorse-hirtellous pedicels; lower calyx lip 2.5-3 mm. long at anthesis, in fruit 4-5 mm. long, the concave scale 3-3.5 mm. tall and clothed like the stems; corolla slender, bluish, the galea and tube 7-10 mm. long, the lower lip hirtellous in 2 lines, the lower filaments seated near the middle of the tube; cocci brown or black, covered with peglike processes, banded. Usually in sandy soils or clays on the edge of and in open woods, roadside banks and flats in e. and n.-cen. Tex., Mar.-June; represented by several variants in much of the e. half of the U.S. and Can.

Represented in Texas by three variants as follows:

1. Stems glabrate to minutely puberulent; pubescence of upper parts ascending, the hairs curled or appressed, not at all glandular (*S. Leonardii* Epl., *S. ambigua* of auth.) var. *Leonardii* (Epl.) Fern.
1. Stems clearly hairy with glandular and nonglandular hairs (2)
- 2(1). Stem with both short retrorse nonglandular hairs and glandular hairs; lateral veins of the leaf not noticeably anastomosing var. *parvula*.
2. Stem with both short curved-ascending nonglandular hairs and glandular hairs on the angles; lateral veins of the leaf arched and anastomosing to form a continuous submarginal vein [*S. australis* (Fassett) Epl.] var. *australis* Fassett.

2. *Scutellaria laevis* Shinn. Low-growing multistemmed perennial to 35 cm. high, the herbage yellowish-green; stems subwoody, glabrous, from a thick woody rootstock; leaves very shortly petiolate, entire, sparingly and minutely scabrous-puberulent to almost glabrous; lower leaves ovate-elliptic, pinnately nerved, somewhat obtuse, 1-2 cm. long, 6-11 mm. wide; upper leaves gradually smaller, elliptic-lanceolate; flowers spicate-racemose, short-pedicellate, with the pedicels scabrous-puberulent; calyx 3-3.5 mm. long, minutely scabrous-puberulent to almost glabrous; corolla pale-white-lavender, 14-17 mm. long, minutely pilose on the exterior; cocci several pressed together, granular-tuberculate to somewhat muriculate. On mt. slopes and in arroyos along dry stream beds, Culberson and Hudspeth cos., Apr.-Sept.; endemic.

3. *Scutellaria Wrightii* Gray. Low perennial 1.5-2 dm. high; stems usually several arising from a woody usually branched crown; pubescence minute, decurved and ap-

pressed, usually curved downward on the leaves, eglandular except for larger sessile resin dots, the calyces sometimes with a few capitate glands; leaves oval, tending to oblong rather than rotund, narrowed at the base to petioles to 3 mm. long, the median 8.5-20 mm. long and 4.5-12.5 mm. broad, rounded at the apex; calyx resinous with sessile glands and usually with decurved hairs, infrequently with spreading capitate glands, the lower lip 3.5-4.5 mm. long at anthesis and somewhat longer in fruit, the scale about 4 mm. tall but broader and flaring; corolla deep-violet-blue, the tube and galea 12-23 mm. long, the lower stamens attached 5-8.5 mm. above the base of the tube, the galea pilose within (especially above the base), the lip glabrous or sparingly pilose in two lines or patches; cocci black and minutely evenly and closely tuberculate. *S. brevifolia* Gray, *S. resinosa* var. *brevifolia* (Gray) Penl. In limestone or chalky soils or sandy loam in prairies, on breaks, bluffs and slopes and in open woods, mostly on the Edwards Plateau, s. to Nueces Co. on the coast and n. to the Plains Country and n.e. to Denton and Cooke cos. in n.-cen. Tex., Mar.-July; also s.w. Okla.

A species closely allied to this one, *S. tessellata* Epl., should occur in Texas. It has been collected in the Guadalupe Mts. in adjacent New Mexico. It differs in that its tessellated cocci have the appearance of a mosaic, and its corolla tubes are generally broadly annulate near the mouth of the calyx. Its leaves are also ovate.

4. *Scutellaria resinosa* Torr. Low perennial 1.5-2 dm. high, often with numerous stems arising in a tuft from a usually massive woody often-branched crown; pubescence of the stems consisting of minute conical spreading hairs, rarely somewhat retrorse, or if ascendent usually so only on the leaves, usually somewhat glandular with larger sessile resin-dots, rarely with capitate glands except on the calyces; leaves shortly petioled, oval, tending to rotund, the median leaves 8-16 mm. long and 4.5-12 mm. wide, rounded at the apex, narrowed toward the base; calyces resinous with sessile glands and with spreading minute hairs, with some of the hairs often capitate-glandular, the lower lip 3.5-5 mm. long at anthesis but somewhat longer at maturity, the scutellum about 4 mm. tall but broader and flaring; corolla deep-violet-blue, the tube and galea 17-22 mm. long, the lower stamens attached 7-10 mm. above the base of the tube, the galea pilose within on both sides, the tube pilose within (especially above the base), the lip glabrous or sparingly pilose in 2 lines or patches; cocci black, minutely evenly and closely tuberculate. On breaks, caprock, banks, slopes and sandhills in the Panhandle, Apr.-Oct.; also in adj. Okla., n. to cen. Kan.

5. *Scutellaria microphylla* Benth. An Erect perennial or sometimes annual, to 4 dm. high, more or less branched throughout, softly pilose throughout with slender spreading glandular hairs; basal leaf blades ovate, commonly 1-1.5 cm. long, with slender petioles about half as long, subcrenate, the median leaves similar but on shorter petioles and entire or subcrenate, the upper entire leaves often scarcely 5 mm. long and subsessile; flowering calyces glandular-pilose, the lower lip 2-3 mm. long but somewhat longer at maturity, the scale then about 2.5-3 mm. tall; corolla violet or bright-blue, its tube and galea 5-11 mm. long, the lower lip glabrous or with 2 small patches of hairs, the throat pilose, the tube nearly glabrous below the lower stamens; lower stamens seated 2.5-4 mm. above the base of the tube; cocci black, finely granulose. On limestone soils on hills, mesas and in canyons on the Edwards Plateau and s. Trans-Pecos, Mar.-July; also n.e. Mex.

6. *Scutellaria Drummondii* Benth. Annual herb commonly 2-3 dm. high, branching at the base when well-developed with the branches commonly procumbent at the base, clothed throughout with slender soft spreading more or less glandular hairs (some retrorse) or sometimes (especially in the lower parts) clothed by retrorse finer hairs; basal leaf blades ovate, commonly 1-2 cm. long, with slender subequal petioles, subcrenate, the median leaves similar but on shorter petioles and commonly entire, the diminished uppermost leaves subsessile and usually entire; flowering calyces pilose and more or less glandular, the lower lip 3-5.5 mm. long but somewhat longer at maturity, the scale then about 3 mm. tall; corolla violet, its tube and galea 5-15 mm. long, the lower lip glabrous or with 2 patches of hairs, the throat pilose, the tube glabrous or nearly so below the point of attachment of the stamens; lower stamen seated 2.5-6.5 mm. above the base of the tube (averaging about 4 mm.); cocci fuscous or black, covered with more or less imbricated lamellae. In sandy, gravelly, clayey or rocky soils, or on rocks, ledges and flats in thickets, chaparral, or on open plateaus and slopes throughout most of Tex., Feb.-July; also w. Okla., s.e. N.M. and n. Mex.

7. *Scutellaria muriculata* Epl. Annual herb 2-3 dm. high, branching at the base and more or less procumbent, the stems with ashy-gray hairs; leaves provided with small curved hairs on both surfaces; lowermost leaves with petioles 7-8 mm. long, ovate to deltoid-ovate, crenate, mostly 1-1.5 cm. long; upper leaves subsessile, subrotund, subentire; flowering calyces with hairs like the leaves, the lower lip about 3.5 mm. long at maturity, the scale about 2 mm. high; corolla-tube blue, with the galea about 12 mm. long, the lower lip glabrous and spotted, the tube subannulate within to the connected stamen; lowest stamens placed on the tube about 3 mm. above base; cocci dark-brown, muriculate. In sandy soil on slopes, knolls, flats and in open woods on the Rio Grande Plains and Valley and along the s. coast of Tex., Jan.-May; undoubtedly also in adj. Mex.

8. *Scutellaria potosina* Brandeg. Perennial herb 2-4 dm. high, usually with several stems arising from a woody usually branched crown; pubescence usually of 2 sorts, composed of small hair that is usually somewhat retrorse and often a longer capitate-glandular hair that is usually spreading or somewhat retrorse, the pubescence of the leaves similar and mostly spreading; leaves shortly petiolate, ovate, variable in size, the median leaves usually 7-8 mm. long, rarely as much as 25 mm. long, rounded at the apex, narrowed at the base to petioles 2-3 mm. long; calyces resinous with sessile glands and thinly clothed with spreading often capitate-glandular hairs, the lower lip 3-4 mm. long at anthesis but enlarging somewhat at maturity, the scale about 4 m. tall but broader and flaring; corolla deep-violet-blue, the tube and galea 8-19 mm. long, the stamens attached 4-7.5 mm. above the base of the tube, the galea pilose within on both sides, the tube pilose within toward the base, subannulate, the lip glabrous or sparingly pilose in two lines or patches; cocci black, evenly and closely coarsely tuberculate. In rocky areas in mts. of the Trans-Pecos, Apr.-Nov.; also N.M., Ariz. and n. Mex.

Those plants with galea and tube about 15 mm. long and stamens inserted about 5.5 mm. above the base of the tube are referred to subsp. *platyphylla* Epl., while those plants with galea and tube about 1 cm. long and stamens inserted about 4 mm. above the base of the tube are referred to subsp. *parviflora* Epl.

9. *Scutellaria integrifolia* L. ROUGH SKULLCAP. Perennial herb 3-7 dm. high; stems rather slender, 1 or several from a subligneous base, simple or with arched-ascending branches above, often with abbreviated axillary branches densely incurved-pilose above, sometimes with divergent hairs, with or without some glands; leaves 3 to 8 pairs below inflorescence; lowest leaves ovate, slender-petioled, crenate; the successively narrower middle and upper leaves mostly oblong to linear-lanceolate and entire, narrowed to petioles to 1 cm. long, punctate, minutely hoary, 2-6 cm. long, up to 1.6 cm. broad; lowest internodes 1-2.5 cm. long; inflorescence a terminal raceme or leafy elongate panicle of 6- to 40-flowered racemes, all but lowest flowers in axils of much reduced foliaceous linear-lanceolate bracts; pedicels short; calyx 2.5-3.5 mm. long in anthesis, becoming 5-7 mm. long in fruit, puberulent; corolla 2-2.5 cm. long, purple-blue and whitish or rarely rose-pink, the large lips subequal; the lower stamens inserted about 8.5 mm. above base of tube; cocci subglobose, blackish, 1.2-1.6 mm. in diameter, covered with rosulate flattish subimbricated papillae. Borders of woods, thickets and clearings, along streams, on seepage slopes and about ponds in e. Tex., Apr.-June; from Fla. to Tex., n. to N.E., O., Ky. and Mo.

The var. *hispida* Benth. has stems with numerous straighter and more divergent hairs, and the transition from lower to median leaves more gradual than in var. *integrifolia*. Plants with rose-pink flowers are designated as f. *rhodantha* Fern.

10. *Scutellaria galericulata* L. MARSH SKULLCAP. Perennial with slender creeping rhizome and mostly subterranean slightly thickened stolons; stems ascending, simple or forking, to 1 m. high, minutely pilose on angles above with recurved hairs; leaves sessile or shortly petioled, oblong-lanceolate to ovate-oblong, crenate, rounded to cordate at base, to 8 cm. long and 3 cm. broad, often somewhat rugose, veiny, minutely pubescent (often canescent) beneath with recurving hairs; flowers solitary in the axils of reduced upper leaflike bracts to form 1-sided interrupted racemes, very short-pedicelled; calyx 3.5-4.5 (in fruit 5-6.5) mm. long, minutely pilose; corolla blue-violet with whitish throat and tube, pilose, 15-25 mm. long; stamens inserted 8-10 mm. above base of tube; cocci pale-olive, 1.5-2 mm. long, with broad low pebbling. *S. epilobiifolia* A. Hamilt. Gravelly, sandy or rocky shores, meadows, marshes, swampy thickets in n. Panhandle, June-July;

from Nfld. and Lab. n.w. to Alas., s. to Del., Pa., W.Va., O., Ind., Ill., Mo., Kan., Tex., N.M., Ariz. and Calif.

11. *Scutellaria cardiophylla* Engelm. & Gray. Annual, 4-6 dm. high, rather strict and stiffish, branching freely above the middle, the branches ascendent and strict, clothed with recurved appressed hairs (particularly along the angles), sometimes with spreading glandular hairs in the lowermost parts as well; basal leaves soon deciduous; median leaves deltoid, lightly cordate, 2-5 cm. long, crenate-dentate, the lower ones borne on petioles as long as the blades, the uppermost sessile and subentire, gradually diminished upward, the upper surfaces of all glabrous, the lower surface hispidulous with spreading hairs, their margins usually ciliate with longer hairs; flowers produced in the upper parts of the plant in the axils of gradually diminished leaves, the pedicels clothed as are the stems; flowering calyces retrorse-pubescent and ciliate on the margins, the lower lip 4-4.5 mm. long at anthesis but 5-6 mm. long at maturity, the scale about 3.5 mm. tall and concave; galea and tube 13-22 mm. long, the tube pilose within, the lip glabrous; lower filaments seated 7-13 mm. above the base of the tube; cocci black, shallowly papillate. Usually in sandy or rocky soils on the edge of woods and in grassy areas in open woods, on banks, in seepage areas and old fields in e. fourth of Tex., w. to Kaufman, Freestone and Madison cos., Apr.-Oct.; also Ark. and possibly w. La.

12. *Scutellaria lateriflora* L. MAD-DOG SKULLCAP. Perennial with filiform rhizomes and stolons; stem to 1 m. high, simple or freely branched, smooth or minutely pilose on the angles with incurved-ascending hairs; leaves with slender pilose petioles to 3 cm. long, ovate to deltoid-ovate, acuminate, coarsely serrate or serrate-dentate, rounded to subcordate at base, thin, glabrous or at most minutely pilose on veins beneath and on margin, to 12 cm. long and 6 cm. broad; racemes 1-sided, axillary and terminal (occasionally reduced to 1 flower), usually with 2 to 44 flowers in the axils of progressively smaller leafy bracts, internodes of lateral racemes mostly 2-7 (rarely -10) mm. long; calyx 2-2.7 (becoming in fruit 3-4) mm. long, puberulent; corolla slender, blue-violet, 5-9 mm. long, pilose; upper stamens inserted about middle of tube; cocci pale, 1.4-1.7 mm. high, obtusely pebbled. In alluvial thickets, meadows, marshes, swampy woods and on seepage slopes in n.e. Tex. and n. Panhandle, July-Sept.; from Ga. to s. Calif., n. to Nfld., Que., Ont., Man., Sask., Alta. and B.C.

13. *Scutellaria ovata* Hill. Stem simple or forking, to about 85 cm. high, erect to somewhat depressed, the middle and upper internodes villous to pilose-hirtellous, with or without gland-tipped hairs; leaves with long slender petioles, cordate-ovate, with deep basal sinus, more or less pubescent to glabrescent, to 13 cm. long, crenate-serrate; racemes terminal, simple, forking or in panicles, the glandular rachis pilose to villous or hirsute; bracts of raceme ovate, the lower bracts merging into the foliage leaves; calyx glandular, in anthesis 3-4 (in fruit 6-8) mm. long; corolla blue with a whitish lower lip, 1-2.3 cm. long, the slender tube flaring to 5 mm. thick at the throat, the lateral lobes almost equaling the short upper lip; the lower stamens seated 8-14 mm. above the base of the tube; cocci buff to orange or brownish, covered with conical papillae. In open woodlands, along roads and on brushy slopes in e. and s. Tex., Apr.-June; represented by several variants mostly in e. and cen. U.S. with the following found in Tex.

1. Middle and usually the lower parts of the stem below the inflorescence pubescent with decurved or retrorse nonglandular hairs . . . subsp. *mexicana* Epl.
1. Stems glandular throughout with spreading capitate glands and usually with shorter somewhat retrorse nonglandular hairs [*S. versicolor* Nutt. var. *bracteata* Benth., *S. ovata* var. *bracteata* (Benth.) Blake] subsp. *bracteata* (Benth.) Epl.

14. *Scutellaria elliptica* Muhl. Hairy SKULLCAP. Stems 1 or few erect from a strong base, to 7 dm. high, pilose with short soft curving hairs or with spreading-divergent hairs, the longest internodes to 15 cm. long; leaves usually few, sparsely strigose-hirsute above, very minutely pilose along the veins beneath, the lower ones with slender-petioled ovate to deltoid blades that are smaller than those above; median and upper leaves cuneate to short petioles, more rhombic-oval, dentate, blunt, 3-6 cm. long and 2-3.5 cm. broad; racemes terminal, 6- to 20-flowered or 3 to 5 (to 7) in a panicle, the rachis curling-pilose; bracts of all but the lowest flowers spatulate to oblong-obovate, entire, exceeding calyx; lowest flowers 1-2 cm. apart; calyx 2.5-3 (in fruit 6-8) mm. long, glandular-hirsute;

corolla 1.4-2 cm. long, pubescent, the tube pale, the unequal lips blue-violet; the lower stamens inserted 6-8 mm. above the base of the tube; cocci subglobose, dark-brown, about 2 mm. in diameter, with many concentric rings of rosulate slightly flattened subimbricated papillae. *S. ovalifolia* Pers., *S. pilosa* Michx. In dry woods and thickets in s.e. Tex., Apr.-June; from Fla. to Tex., n. to N.Y., N.J., Pa., W.Va., Mich., O. and Mo.

Those plants whose stems have numerous divergent hairs 1-2 mm. long and whose median and upper leaves are more deltoid-ovate are segregated as var. *hirsuta* (Short) Fern.

6. HYPTIS JACQ.

About 400 species, mostly in tropical America.

1. *Hyptis alata* (Raf.) Shinn. CLUSTER BUSHMINT, DESERT-LAVENDER. Herbaceous perennial from a woody rootstock; stem stout and elongate, to about 2 m. high, finely pubescent, simple or rarely branched; leaves ovate to rhombic-lanceolate or linear-lanceolate, to about 15 cm. long and 5 cm. wide, coarsely and irregularly serrate, cuneately narrowed into a petiolar base; flowers in dense axillary glomerules about 2 cm. thick that are supported by peduncles to 5 cm. long; calyx 6-8 mm. long, the tube strongly cross-ribbed at maturity, the lobes subulate-lanceolate and short-hairy; corolla declined, 2-lipped, white with lavender dots, 8-10 mm. long, the upper lip with 4 entire lobes, the lower lip saccate, abruptly deflexed at the contracted and callous base; stamens 4, declined or resting on the lower lip, didynamous; disk entire or with a gland on the anterior side; cocci oval, nearly 1.5 mm. long. *Hyptis radiata* Willd. In low pinelands, seepage areas, swamps and marshes in s.e. Tex., June-Nov.; from Fla. to Tex., n. to N.C.

7. MARRUBIUM L.

About 45 species, all in the Old World.

1. *Marrubium vulgare* L. COMMON HOREHOUND, MARRUBIO. Perennial aromatic herb with bitter sap; stem with stout erect or ascending branches, to about 1 m. high, white-woolly (especially below); leaves with petioles 1-2 cm. long, oval to broadly ovate or suborbicular, to about 5 cm. long, crenate-dentate, rugose-veined, obtuse to rounded at apex, narrowed to subcordate at base, woolly beneath, canescent above; flowers whitish, in dense axillary clusters; calyx cylindric, 4-5 mm. long; calyx teeth usually 10, subulate, more or less recurved; corolla white, 5-6 mm. long, 2-lipped, the upper lip erect and entire or emarginate, the spreading lower lip 3-cleft with its middle lobe broadest and often emarginate; stamens 4, included, didynamous, the posterior pair shorter; anthers 2-celled; styles cleft into 2 short lobes at summit; ovary deeply 4-lobed; cocci ovoid, smooth, about 2 mm. long. In waste places, along roadsides, about corrals, animal pens and along roadsides throughout most of Tex., flowering throughout year; nat. of Euras. but naturalized throughout much of N.A.

The flowering tops and dried leaves are used medicinally and as a flavoring.

8. SIDERITIS L. IRONWORT

About 100 species in North Temperate Eurasia.

1. *Sideritis lanata* L. Annual, branched from base to form a globose habit, 3 dm. high or more, villous or woolly-villous throughout; leaves with winged petioles to 15 mm. long, ovate to oval, broadly cuneate to rounded at base, obtuse at apex, crenate, to 3 cm. long and 2 cm. wide; verticils several-flowered, about 1 cm. apart in an elongate raceme, subtended by persistent leafy bracts; pedicels about 1 mm. long; calyx campanulate-funnelform; bilabiate, the tube to 5 mm. long, with 5 sharp unequal spiny-tipped teeth; corolla 6-8 mm. long, exerted, the slender cylindrical tube white, the bilabiate limb marked or suffused with dark-purple or nearly black, the upper lip with 2 linear lobes about 2 mm. long, the lower 3-lobed lip with 2 short triangular lateral lobes and an orbicular midlobe 1.5 mm. in diameter; cocci 2 mm. long, brown, pitted. A

nat. of Greece and Asia Minor that is adv. on sandy banks in oak-mesquite area in Llano Co. on the Edwards Plateau, Apr.-June.

9. MOLUCELLA L.

Two species that are native to the Mediterranean region.

1. *Molucella laevis* L. SHELL-FLOWER. Annual herb; stems erect, glabrous, simple or branched, to about 8 dm. high; leaves suborbicular, coarsely toothed with broad rounded teeth, to about 5 cm. long, with slender petioles about as long as the blade; flowers fragrant, several in the axils of the leaves, subtended by several slender spreading or reflexed spines; calyx campanulate, the lobes united into a broadly dilated funnelform membranous reticulate-veined structure 2-2.5 cm. long, subtended by several spines; corolla included, white tipped with pink, bilabiate, the upper lip arched and including the stamens, cocci 4, convex on one side, angular on the other, broader upward, truncate. An occasional escape from gardens, nat. of w. Asia.

10. AGASTACHE CLAYT.¹⁶³

Erect herbs with perennial rootstocks; leaves serrate, mostly petioled; flowers small, in dense verticillate clusters that form compact or interrupted terminal bracted spikes; calyx campanulate or tubular, somewhat oblique, usually 15-nerved, slightly 2-lipped, tho upper lip with 2 (the lower lip with 3) approximately equal teeth; corolla tube not exceeding the calyx, the limb conspicuously 2-lipped, the erect upper lip 2-lobed, the spreading lower lip 3-lobed with the middle lobe crenate; stamens 4, all fertile, exerted, divergent or distant, the upper pair usually declined, the lower shorter and ascending; anther cells parallel or nearly so, both fertile; style 2-cleft at summit; ovary deeply 4-parted; cocci ovoid, commonly smooth.

A North American genus of about 30 species.

1. Flowers in elongate spikes 1 cm. or less thick; calyx tube 2 mm. long or less; corolla tube 2.5-5 mm. long 1. *A. micrantha*.
1. Flowers in short congested spikes or heads mostly more than 1 cm. thick; calyx tube usually more than 3 mm. long; corolla tube 6-30 mm. long (2)
- 2(1). Leaf margins entire above the middle, sparsely toothed below middle 2. *A. cana*.
2. Leaf margins crenate or crenate-dentate from base to apex (3)
- 3(2). Corolla usually rose-purple, the tube 6-10 mm. long 3. *A. breviflora*.
3. Corolla whitish to rose-purple, the tube 9-18 mm. long 4. *A. pallidiflora*.

1. *Agastache micrantha* (Gray) Woot. & Standl. Stems to about 6 dm. high or more, with slender erect subfastigiate branches, finely pubescent; leaves deltoid-lanceolate, thin; median leaves with petioles 1-1.5 cm. long, 3-6 cm. long and 1-2.5 cm. wide, acute, mostly rounded or cuneate at the base, coarsely serrate (mostly below the middle), both surfaces hirtellous or pubescent with fine hairs; basal leaves reniform, hirsute, with slender petioles about twice as long as the blades; inflorescence continuous or somewhat moniliform, at least the upper whorls usually crowded, 8-20 cm. long and to 1 cm. thick; calyx green, minutely hirtellous with spreading hairs, the tube 2-3 mm. long; calyx teeth to 1 mm. long, commonly whitish, acute, unequal, their margins thin; corollas white, scarcely or not at all exerted from the calyx, the tubes 2.5-3 mm. long; stamens less than 1 mm. long, scarcely exerted; cocci to 1 mm. long, glabrous. In rocky or sandy soils or on ledges in mts. of the Trans-Pecos, July-Oct.; from Tex. to Ariz. and n. Mex.

2. *Agastache cana* (Hook.) Woot. & Standl. MOSQUITO PLANT. Stems to about 6 dm. high, with numerous slender ascending branches, arising from a woody crown, minutely

¹⁶³ Adapted from Harold Lint and Carl Epling in Am. Midl. Nat. 33:207-230. 1945.

puberulent; lower leaves with slender petioles about as long as the blade, deltoid to deltoid-ovate, coarsely crenate-serrate, 1-3 cm. long, the mostly entire median leaves ovate-lanceolate and 1-2 cm. long, the uppermost leaves nearly sessile, both surfaces minutely puberulent but green, about equally pitted with sessile glands; verticils 6- to 12-flowered, mostly 1-2 cm. distant, shortly pedunculate, forming a loose narrow panicle or interrupted spike as much as 3 dm. long, the internodes of the rachis about as long as the pedicels, evident; calyx turbinate, whitish or tinged with rose, the tube 5.5-7.5 mm. long, thinly hirtellous with spreading hairs; calyx teeth narrowly deltoid, 1.5-3.5 mm. long, acute to acuminate; corolla rose-color, thinly hirtellous to glabrous, the tube 16-25 mm. long; cocci 1.5-2 mm. long, usually puberulent. On rocky slopes and in crevices of ledges in w. Trans-Pecos, July-Oct.; also N.M.

3. *Agastache breviflora* (Gray) Epl. Stems to about 6 dm. high, with ascending often subcorymbose branches, arising from a woody caudex, hirtellous, the internodes elongate; leaves with petioles mostly less than 1 cm. long, deltoid-ovate, the upper leaves sometimes narrowly deltoid, the lower leaves deltoid-cordate, 2-4 cm. long, obtuse to rounded at the apex or the upper ones acute, truncate to subcordate at the base, coarsely crenate-serrate, the upper surfaces hirtellous and green, the lower surface more or less pubescent, or both surfaces nearly glabrous; verticils sessile, approximate in continuous spikes mostly 5-10 cm. long and 1.5-2 cm. in diameter, the lower whorls sometimes distant; calyx usually rose-color, hirtellous with spreading hairs, the tube 3.5-5.5 mm. long, the firm teeth tending to be subulate; corolla rose-color or purplish, the tube 6-10 mm. long; stamens 1.5-2.5 mm. long, scarcely exerted beyond the lip; cocci about 1.5 mm. long. *A. verticillata* Woot. & Standl. In crevices of rocks and near summit of mts. in the Trans-Pecos, July-Oct.; from Tex. to Ariz. and n. Mex.

4. *Agastache pallidiflora* (Heller) Rydb. Stems usually simple, to about 6 dm. high, rarely to 1 m. high, ascending from a woody caudex; leaves with petioles rarely to 2 cm. long, prevailingly deltoid-ovate, to 6 cm. long and 55 mm. wide, usually much smaller, mostly obtuse at apex, truncate to shallowly cordate at the base, crenate-serrate, hirtellous on the upper surface but green, finely and usually sparingly pubescent on the lower surface, sometimes nearly glabrous; verticils sessile, usually crowded into continuous cylindrical spikes, the lowermost verticils sometimes approximate or remote; calyx green, rose or deep-rose-purple, hirtellous with spreading hairs, the tube usually 5-8 mm. long, the deltoid to almost subulate teeth quite variable in shape and relative size (1-4 mm. long); corolla whitish to rose-color, their tube 9-18 mm. long. In humus in mt. forests in the Trans-Pecos, June-Oct.; from Tex. to Ariz. and n. Mex. The following variants occur in Texas.

Subsp. *Havardii* (Gray) Lint & Epl.: calyx tube tinged with violet or rose, 4-5 mm. long, the teeth 1.5-3 mm. long, tending to flare somewhat; corolla (?) rose, the tube 9-11 mm. long. *A. brevifolia* var. *Havardii* (Gray) Shinnars.

Subsp. *neomexicana* (Briq.) Lint & Epl.: calyx rose (at least on the teeth), the tube mostly 5-8 mm. long; corolla rose, the tube 9-15 mm. long. *Agastache neomexicana* (Briq.) Standl., *Brittoniastrum neomexicanum* Briq.

11. NEPETA L.

CATMINT

A genus of about 250 species, all of which are natives of Eurasia and Africa.

1. *Nepeta Cataria* L. CATNIP. Perennial erect herb with pale-green and densely canescent herbage; stems to about 1 m. high, with ascending branches; leaves petioled, ovate to triangular-ovate or oblong, to about 8 cm. long and 5 cm. wide, acute at apex, usually cordate at base, coarsely dentate or crenate-serrate; flower verticils in the axis of small foliaceous bracts to form dense or interrupted terminal spikes; bractlets subulate; calyx urceolate, slightly oblique at apex, about 6 mm. long, very pubescent, the 5 subulate teeth about half as long as the tube, short-pubescent on the prominent 15 nerves; corolla white to pale-purple, dotted with dark-purple, strongly 2-lipped, 1-1.2 cm. long, puberulent on the outer surface, the upper lip erect and somewhat 2-lobed, the broad middle lobe of the 3-lobed lower lip crenulate; stamens 4, all fertile, didynamous, ascending under the upper lip; anther sacs 2, divergent; ovary deeply 4-parted; style 2-cleft at

summit; cocci ovoid, compressed, smooth. In waste places in e. and cen. Tex., May-Sept.; a nat. of Eur. that is naturalized in various parts of N.A.

12. PRUNELLA L.

About 7 species of world-wide distribution.

1. *Prunella vulgaris* L. COMMON SELF-HEAL, HEAL-ALL, CARPENTER-WEED. Perennial herb with simple or several stems and slender rootstocks, tufted or loosely ascending from leafy-tufted bases, to about 6 dm. high, usually much smaller, glabrous or commonly pilose (especially above); leaves ovate to ovate-lanceolate or oblong-lanceolate, 3-7 cm. long and about a third as wide, acute to acutish or sometimes rounded at apex, narrowed to a short or elongate petiole, entire or irregularly and remotely toothed; flowers in clusters of 3, sessile in the axils of round and bractlike membranaceous floral leaves, imbricated in a close spike 2-5 cm. long; bracts orbicular to broadly ovate, cuspidate, more or less bristly-ciliate, green or often tinged with purple; calyx tubular-campanulate, about half as long as the corolla, usually 10-nerved, naked in the throat, closed in fruit, deeply 2-lipped, the upper lip truncate or with 3 short often ciliate teeth, the lower lip cleft into 2 lanceolate often ciliate teeth; corolla 1-2 cm. long, violet or rarely white, ascending, strongly 2-lipped, the upper lip arched, the lower lip spreading and 3-lobed; stamens 4, didynamous, ascending under the upper lip, the lower pair longer; filaments 2-toothed at apex with one of the teeth bearing the anther, the other sterile; anther cells 2, divergent; ovary deeply 4-parted; cocci ovoid, smooth. In low meadows, open woodlands, along roadsides and pasturelands in the e. fourth of Tex., Apr.-June; widespread throughout the N. Hemis.

This species is represented in Texas by var. *hispida* Benth. with densely pubescent stems and lower surface of leaves, and var. *lanceolata* (Bart.) Fern. with narrow leaves.

13. BRAZORIA ENGELM. & GRAY¹⁶⁴

Annual herbs; leaves typically oblong, sessile or petiolate, denticulate, reduced above to bracts; flowers in virgate racemes or spikes; calyx more or less inflated and essentially closed at maturity, bilabiate, the upper lip with 3 lobes, the lower lip with 2 lobes; corolla pink to rose-purple or bluish, more or less variegated, bilabiate; stamens 4; anthers 2-celled, the sacs parallel or nearly so; cocci 3-angled.

A genus endemic to Texas and Oklahoma.

1. Stem glabrous toward base; corolla 9-14 mm. long; plant of calcareous rocky or clayey soils 1. *B. scutellarioides*.
1. Stem pubescent or hispidulous at base; corolla 13-28 mm. long; plant of light sandy or sandy-clay soils (2)
- 2(1). Pubescence of inflorescence of long simple hairs to 2 mm. long; calyx conspicuously bearded with long hairs; flowers in short dense subspicate racemes 2. *B. truncata*.
2. Pubescence of inflorescence of short hairs; calyx not bearded; flowers in elongated open interrupted subspicate racemes (3)
- 3(2). Stem leaves mainly at base, with 3 to 5 pairs of stem leaves below inflorescence, the upper reduced to clasping bracts, the basal leaves persistent; middle calyx lobe of upper lip rounded and entire, not subulate-apiculate, the 2 lobes of lower lip not overlapping, the sinus open 3. *B. arenaria*.
3. Stem leaves at base withering early, not persistent, with 5 to 8 pairs of stem leaves below inflorescence, large and spatulate, not reduced above to clasping bracts; middle calyx lobe of upper lip truncate-rounded and subulate-apiculate, the 2 lobes of lower lip overlapping, the sinus closed 4. *B. pulcherrima*.

¹⁶⁴ Ref.: Lloyd H. Shinnars in *Field & Lab.* 21:153-154. 1953; C. L. Lundell in *Wrightia* 4:29-30. 1968, and *Flora of Texas* II: 319-330. 1969.

1. *Brazoria scutellarioides* Engelm. & Gray. PRAIRIE BRAZORIA. Stem glabrous below the inflorescence, erect, to about 45 cm. high, paniculately branched above; leaves sessile and partly clasping at base, oblong to oblong-lanceolate or oblong-spatulate, acute, serrate above the middle; spikes or racemes loosely flowered, paniced, to 2 dm. long, the rachis (and calyx) densely and minutely pubescent; bracts ovate to lanceolate, 3-6 mm. long, ciliolate; calyx deeply and unequally bilabiate, 3-4 mm. long, becoming 5 mm. in fruit, the lobes (except the middle and upper lip) pointed with a rather conspicuous cusp, in fruit the upper ovate-rounded lobes are somewhat curved backwards while the narrow lower lip is incurved so as to nearly close the orifice; corolla pinkish or flesh-color; anthers purplish, slightly ciliolate; cocci rather granular, glabrous, about 1 mm. thick. In calcareous soils in cen. Tex., Mar.-May; also Murray Co., Okla.

2. *Brazoria truncata* (Benth.) Engelm. & Gray. Stem stout, somewhat pubescent, to 5 dm. high, simple or branched at base; leaves oblong to oblanceolate or spatulate, to about 1 dm. long, the lower leaves tapering to a long winged-petiole, the upper leaves sessile and partly clasping; spike densely flowered, stout, viscid-hairy, to 15 cm. long; floral bracts orbicular, apiculate, with long white marginal hairs; calyx about 5 mm. long, becoming 8-9 mm. in fruit, acutely toothed, with a tuft of hairs at base; corolla slightly puberulent along the back, 1.5-2 cm. long, the tube spotted with purple, lobes of the lower lip emarginate; cocci 1.5 mm. thick, pubescent, contained in a gibbous cavity on the upper side of the calyx which is flat on the lower side and very gibbous at the base on the upper side. In sandy soils in s.-cen. Tex., Apr.-May; endemic.

3. *Brazoria arenaria* Lundell. SAND BRAZORIA. Stem to about 4 dm. high, branching at the base, erect or ascending, pubescent with short hairs; leaves membranaceous; basal leaves long-petiolate, oblong-elliptic to elliptic-oblanceolate, to 12 cm. long and 35 mm. wide, attenuate at base, rounded at apex, denticulate, glabrous beneath, with a few short hairs along midrib at base of blade above; cauline leaves few, sessile, remote, linear-oblong to oblong-oblanceolate or oblong-obovate, denticulate, reduced above to clasping bracts; racemes to 3 dm. long, interrupted, remotely flowered, pubescent with short glandular and nonglandular hairs; bracts broadly elliptic to ovate-elliptic, at most ciliate, obtuse to acute, 3.5-5 mm. long; calyx campanulate, broadly toothed, about 5.5 mm. long, becoming 9 mm. long in fruit, puberulent at base, the lips subequal; calyx tube pubescent with short nonglandular and glandular hairs, not bearded, the upper lip of 3 broad rounded lobes, the lateral lobes apiculate, the middle lobe rounded, the lower lip slightly longer, shallowly 2-lobed, the lobes sharply dentate with 3 to 5 short subulate teeth; corolla lavender with maculate throat, sparsely puberulent along the back, 13-18 mm. long, the tube dilated upward, the upper lip with 2 oblong subentire lobes, the lower lip with 3 smaller lobes that are emarginate at the apex; cocci pubescent, 2 mm. in diameter. In sandy soils in the Rio Grande Plains, Mar.-Apr.; endemic.

4. *Brazoria pulcherrima* Lundell. Annual to 6 dm. high; stems with rounded angles, simple or branched near base, pubescent with short hairs; leaves membranous, the basal withering early, with 5 to 8 pairs of stem leaves below the inflorescence, spatulate, to 13 cm. long and 2.5 cm. wide, rather remotely crenate-denticulate above middle, acutish to obtusish at apex, the upper leaves winged at base, the lower petiolate, short-pubescent above at base (otherwise glabrous); racemes subspicate, paniced, interrupted, remotely flowered, to 35 cm. long, the rachis pubescent with short glandular and nonglandular hairs; bracts ovate, 6 mm. long, subulate-acuminate, conspicuously ciliate with long hairs; pedicels to 2 mm. long, slender; calyx campanulate, not bearded, short-pubescent with glandular and nonglandular hairs, about 6 mm. long, becoming 8 mm. long in fruit, the 3 lobes of upper lip truncate-rounded, each lobe subulate-apiculate, the 2 lobes of lower lip each with 2 to 5 subulate teeth, the lateral teeth often reduced, the lobes overlapping medially to close the sinus; corolla lavender with maculate yellow throat, sparsely pubescent along the back, to 22 mm. long, the tube dilated upward, the upper lip with 2 rounded conspicuously toothed lobes, the teeth rounded, the lower lip with 3 smaller emarginate lobes, the upper lip villous at base within throat; cocci 3-angled, about 1.8 mm. long, hirtellous. Sandy soils along roadsides and open fields near Centerville, Leon Co., Tex., Apr.-June; endemic.

14. *PHYSOSTEGIA* BENTH.¹⁶⁵

FALSE DRAGON-HEAD. OBEDIENT-PLANT

Smooth perennial herbs with upright simple or sparingly branched stems; leaves sessile or the lower ones sometimes petiolate, linear to lanceolate or oblong, mostly crenate or dentate; flowers usually large and showy, opposite, scattered or crowded in simple or paniced terminal leafless spikes; calyx regular, obscurely 10-nerved, short-tubular to campanulate, more or less enlarged and slightly inflated in fruit; corolla funnel-form, the tube exceeding the calyx, with a much-inflated throat, varying from white to rose-color and commonly spotted or variegated with purple, 2-lipped; upper corolla lip erect, nearly entire; lower corolla lip 3-parted, spreading, small, its larger middle lobe broad and rounded, notched; stamens 4, ascending beneath the upper corolla lip; cocci ovoid, smooth.

About a dozen species that extend from Canada to northern Mexico. The vernacular name, "obedient-plant," is derived from the fact that when the flowers are moved laterally in the inflorescence they remain where placed. All of these species have value as ornamentals.

1. Corolla rarely to 2 cm. long (2)
1. Corolla more than 2 cm. long (3)
 - 2(1). Corolla less than 1 cm. long; calyx 3-4 mm. long . . . 1. *P. micrantha*.
 2. Corolla more than 1 cm. long; calyx 5 mm. long or more 2. *P. intermedia*.
- 3(1). Plant mostly slender and to about 1 m. high; leaves on lower half of stem linear to linear-lanceolate, rarely more than 15 mm. wide (4)
3. Plant large, coarse, commonly above 1 m. high; leaves on lower half of stem elliptic to oblong-elliptic or oblong-lanceolate, 20 mm. wide or more (5)
- 4(3). Flowering from April to July 3. *P. angustifolia*.
4. Flowering from August to November 4. *P. praemorsa*.
- 5(3). Distribution in Val Verde County, commonly in flowering water; rhizome large and elongate 5. *P. Correllii*.
5. Distribution in eastern half of Texas, in dry or wet soil; rhizome short and thick (6)
- 6(5). Corolla very pale lavender-pink or whitish; mostly in sandy or gravelly soils 6. *P. Digitalis*.
6. Corolla reddish purple or deep lavender-pink, the lobes purplish; mostly in wet clayey soils 7. *P. pulchella*.

1. *Physostegia micrantha* Lundell. Erect rhizomatous herb to 9 m. high, slender, the internodes progressively longer from base to apex, the upper nodes puberulent, otherwise glabrous below the inflorescence; leaves small, glabrous, chartaceous, linear-lanceolate or oblong-lanceolate, acute to acuminate, to 12 cm. long and 11 mm. wide, the basal leaves petiolate, the medial leaves largest, sessile, clasping at base, the apical leaves bractlike below the inflorescence; leaf margin repand to sinuate, rather remotely and inconspicuously denticulate; inflorescence to 2 dm. long, slender, usually simple, sometimes with 2 lateral branches at the basal node, densely puberulent; bracts shorter than the calyx, puberulent; flowers subsessile, the puberulent pedicels about 1 mm. long; calyx pellucid-punctate, puberulent, 3-4 mm. long, the acute teeth slightly shorter than tube; corolla white, tinged lavender or pink, puberulent, 5-7 mm. long, the campanulate tube shorter than the calyx; filaments glabrous. Wet bottomland along creek in Titus Co., May-June; endemic.

2. *Physostegia intermedia* (Nutt.) Engelm. & Gray. Slender, rhizomatous, 3-15 dm. high; leaves dark-green, linear-lanceolate to linear, thickish, the larger 3-12 mm. broad, the margin repand-sinuate and entire or rarely obscurely dentate, all but the lowest attenuate, the uppermost greatly reduced; spike very slender, much-interrupted, the lateral ones (if developed) strictly erect, the rachis 5-35 cm. long; corolla lavender,

¹⁶⁵ Ref.: C. L. Lundell in *Wrightia* 2:4-12, 66-74. 1959-1960, and *Flora of Texas* II: 319-330. 1969. See Appendix.

purple-spotted in throat, 1-1.5 cm. long, rarely more. Usually found in wet periodically flooded areas or even growing as an aquatic along ditches, in swamps, marshes and bottomlands in e. and most of s. half of Tex., Apr.-June; from Ky. to Kan., s. to Ala., La. and Tex.

3. *Physostegia angustifolia* Fern. Stem stiffly erect, with rhizomes to 3 dm. long, to about 2 m. high; leaves rigid, sessile or the lower ones with slender petioles to 2 cm. long, grayish or pale, linear to narrowly lanceolate or oblong-lanceolate, the lower leaves obtuse to subacute; median leaves attenuate and appressed-acerose-serrate, to 13 cm. long and 12 mm. wide, rarely larger, the uppermost leaves passing rather abruptly into the small leafy bracts of the inflorescence; spikes slender, virgate, solitary or with few erect laterals, to 35 cm. long, remotely flowered; branches of inflorescence, bracts and calyces finely and densely pubescent with nonglandular hairs; calyx 6-10 mm. long; corolla pale- to deep-purple or whitish, purple-spotted, 2.5-3 cm. long; cocci dark-brown, 3 mm. long or more. *P. edwardsiana* Shinnars. In marshy areas, along streams, roadsides and fields and meadow in e. and cen. Tex., Apr.-July; from Ill. to Tenn., s. to Miss., La. and Tex.

4. *Physostegia praemorsa* Shinnars. Perennial with rhizomes; stem glabrous, to about 12.5 dm. high; lower leaves shortly petiolate, narrowly oblong to lanceolate or oblong-lanceolate, acute, 3-7 cm. long, 5-13 mm. wide, the margins sharply serrate except near base, gradually reduced above to sessile linear-lanceolate bracteal leaves; inflorescence simple or virgately branched, with the bracts and calyx densely and minutely pubescent with glandular and nonglandular hairs; calyx 6-10 mm. long, the teeth narrowly deltoid-lanceolate; corolla showy, light-lavender-violet to whitish, with rose-purple spots, 22-32 mm. long, the tube 7-14 mm. long, often exerted from calyx; cocci dark-brown, about 4 mm. long, sharply 3-angled. *P. serotina* Shinnars. Along streams and ditches, in moist grasslands in e. n.-cen. Tex., with a disjunct area in the Guadalupe Mts., Aug.-Oct.; also La. and N.M., probably also Okla.

5. *Physostegia Correllii* (Lundell) Shinnars. Plants erect, robust, somewhat succulent, to 22 dm. high, with thick creeping rhizomes; stems simple or sparingly branched, to 25 mm. thick, glabrous, as many as 20 nodes per stem; leaves decussately opposite, sessile, leathery and firm, elliptic or oblong-elliptic, 5-13 cm. long, 2-6.5 cm. wide, short-acuminate at apex, slightly narrowed at base and inconspicuously clasping, the margin conspicuously and sharply serrate-dentate to base, primary veins usually 2 or 3 on each side, the upper leaves only slightly reduced; racemes spikelike, simple or compound, short, leafy at base, finely pubescent, comparatively few-flowered; bracts leafy, ovate, those at base of raceme equal to or longer than calyx, reduced above, acuminate; pedicels very short, about 1 mm. long in fruit; calyx finely pubescent, gland-tipped hairs abundant, subcylindric, 8-9.5 mm. long, the acuminate lobes slender and subequaling tube, inflated at maturity; corolla lavender-pink, spotted or streaked with purple, about 3 cm. long, sparsely pubescent; cocci about 2.3 mm. long, sharply angled. *Dracocephalum Correllii* Lundell. In water along streams and in irrigation ditches in Val Verde Co., June-July; also N.L.

6. *Physostegia Digitalis* Small. Stems erect, to 2 m. high, stout, sharply angled; leaves several, sessile and partly clasping at base, somewhat leathery-thickened, oblong to elliptic-oblong, to 22 cm. long and 75 mm. wide, acute to subacute, the margins undulate or repand-serrate above the middle; raceme simple or compound, finely pubescent; bracts ovate-lanceolate to lanceolate, 4-6 mm. long; pedicels very short; calyx 8-10 mm. long, the tube turbinate or cylindrical-turbinate, the lanceolate lobes acuminate and about one half as long as the tube; corolla pale-lavender to whitish, commonly with reddish-purple dots, 2-2.5 cm. long, barely puberulent dorsally, the upper lip slightly undulate, the lower lip spreading with the lobes oblong (the middle lobe emarginate and about twice as long as the others). *P. obovata* of auth. In sandy open pinelands, edge of forests, prairies, grasslands and swampy areas in e. Tex., June-Aug.; from e. Tex. to La., Ark. and probably Okla.

7. *Physostegia pulchella* Lundell. Erect rhizomatous herb to 14 dm. high, slender or robust; stem to 15 mm. in diameter near base; basal leaves chartaceous, usually with slender petioles to 8 cm. long, expanded and clasping at base, narrowed above, entire to subentire or remotely dentate; leaves above base oblong-lanceolate or oblong-elliptic, to 12 cm. long and 25 mm. wide, tapering into a winged petiole, obtuse at apex, the margin

subentire to denticulate; leaves of middle stem rather firm, chartaceous, pallid, oblong to oblanceolate-oblong or oblong-elliptic, 7.5-15 cm. long, 1-2 cm. wide, sessile and clasping at base or with a broadly winged petiole below, the apex acute or obtuse, the margin usually serrate to base or sometimes subentire below; apical leaves bractlike below the inflorescence; inflorescence densely pubescent throughout, simple or with two or more lateral branches from the basal bracts, usually less than 3 dm. long, sometimes to 6 dm. long; flowers rather remote, not crowded, subsessile, subtended by small ovate acuminate bracts 2-3 mm. long; pedicels in fruit not over 1.5 mm. long; calyx tubular-campanulate, 6-7 mm. long at anthesis, the pellucid-punctate acute teeth ovate-deltoid or ovate and 1.5-2 mm. long; corolla pink-lavender to deep reddish-purple, the lobes purplish, the throat red-purple striped or maculate, finely pubescent, 2-3 cm. long, the tube subequaling the calyx, the upper lobe entire, the lower lobes inconspicuously emarginate and subentire; filaments villous below; anthers glabrous or sparsely short-villous; fruiting calyx turbinate, 6-7 mm. long, about 5 mm. in diameter at base, the rigid teeth slightly incurved; cocci brown, 3-angled, about 3 mm. long, the ridges hyaline. In wet soil of bottomlands along streams mostly in e. Tex., May-June; endemic.

15. STACHYS L.¹⁶⁶ HEDGE-NETTLE

Annual, biennial or perennial herbs, mostly pubescent or hispid; flowers in verticils to form dense or interrupted terminal racemes or spikes, sometimes in the upper leaf axils; calyx usually campanulate, 5- to 10-nerved, 5-toothed with the teeth nearly equal and erect or spreading; corolla mostly reddish or purplish, the narrow tube not dilated at the throat and strongly 2-lipped; upper corolla lip erect, often arched, concave, entire or emarginate; lower corolla lip spreading, 3-lobed, the middle lobe broader than the often deflexed lateral ones and sometimes 2-lobed; stamens 4, didynamous, ascending under the upper corolla lip, the anterior pair the longer; anthers contiguous in pairs, the sacs divergent; ovary deeply 4-lobed; style 2-cleft, the lobes subulate; cocci ovoid or oblong, obtuse.

Nearly 300 species mostly in the North Temperate Zone, with several in South America and South Africa.

- 1. Distribution in mountains of Trans-Pecos Texas; plant perennial (2)
- 1. Distribution east of the Trans-Pecos region; plants annual, biennial or perennial (3)
- 2(1). Corolla scarlet, the tube 15-21 mm. long; rare in the El Paso region 1. *S. coccinea*.
- 2. Corolla pink or pink-lavender, the tube 8-13 mm. long; occasional in the central and southern Trans-Pecos region 2. *S. Bigelovii*.
- 3(1). Plant annual or biennial, mostly in central and south Texas (4)
- 3. Plant perennial; in extreme east Texas (5)
- 4(3). Calyx teeth mostly longer than the tube; lower lip of corolla noticeably surpassing the calyx 3. *S. Drummondii*.
- 4. Calyx teeth about as long as or shorter than the tube; lower lip of corolla only slightly surpassing the calyx 4. *S. crenata*.
- 5(3). Plant glabrous or nearly so; inflorescence essentially glabrous; petioles less than one fourth as long as the blades 5. *S. tenuifolia*.
- 5. Plant more or less hirsute; inflorescence puberulent or glandular-puberulent; petioles one third to one half as long as the blades 6. *S. floridana*.

1. *Stachys coccinea* Jacq. TEXAS BETONY. Perennial with assurgent to erect stems, to 1 m. high or more, rather stout, pubescent with long soft spreading hairs below, less so upward, very obscurely resiniferous-viscid beneath the indument throughout; leaves broadly to narrowly triangular-ovate to ovate-lanceolate, dentate-serrate, dark-green and short-pubescent above, paler and densely pubescent beneath, subacute at apex, rounded to truncate or subcordate at base, the lower leaves to 8 cm. long, gradually smaller upward

¹⁶⁶ Adapted from Carl Epling in Repert. Sp. Nov. 80:1-75. 1934.

and passing into the sessile foliar bracts of the verticils, the petioles of lower leaves equaling or exceeding the blades; inflorescence an open interrupted spike; verticils mostly 4-flowered; flowers usually distinctly pedicelled; calyx deeply and narrowly campanulate, its tube 5-6 mm. long, with 5 triangular acute cuspidate teeth half as long as tube; corolla scarlet, 18-24 mm. long, its tube twice as long as the calyx and transversely annulate near base, strongly bilabiate, the entire upper lip broadly ovate to subreniform and 7-8 mm. in diameter, the lower lip deeply divided with the middle lobe ovate and the lateral lobes oblong-spatulate. In moist crevices of steep stony slopes in mts. of the Trans-Pecos; w. to Ariz. and n. Mex.

2. *Stachys Bigelovii* Gray. ROCK BETONY. Perennial, branched, to about 6 dm. high; the herbage sparsely or densely minutely cinereous-pubescent; leaves with petioles to 5 cm. long, triangular-ovate to triangular-lanceolate, obtuse to acute at apex, broadly rounded to truncate or cordate at base, to 6 cm. long and 4 cm. wide; flowers few in the clusters, almost sessile or with pedicels to 2 mm. long; calyx tube 5-6 mm. long, oblong-campanulate, with subulate teeth 2.5-5 mm. long; corolla pink to pink-lavender or purplish, its tube 8-13 mm. long. Under oaks, on rocky slopes and ledges and in crevices in mts. of the Trans-Pecos, June-Oct.; probably also n. Mex.

Two forms are found in Texas. Those plants in the Chisos Mts. usually are less pubescent, have narrower, more dentate leaves, and a more slender corolla tube.

3. *Stachys Drummondii* Benth. PINK MINT. Annual or biennial, softly hirsute; stems solitary or tufted, to 9 dm. high, usually branched from below middle; leaves with petioles about as long as the leaf blades or shorter, broadly ovate to ovate-oblong, to 1 dm. long, obtuse at apex, crenate, truncate to cordate at base; clusters few-flowered; pedicels 1-2 mm. long; bracts spine-tipped; calyx tube 5-6 mm. long, turbinate; calyx lobes lanceolate, acuminate, subulate-tipped, as long as the tube or longer; corolla lavender or pink, appressed-pubescent, about 1 cm. long, the tube shorter than the calyx, the upper lip notched, the lower lip twice as long as the upper one and its lobes truncate or retuse at the apex; cocci nearly 2 mm. long, dull. In clayey soils, sandy or gravelly loam in chaparral, open woods, palm groves and brushlands in s. and coastal Tex., Feb.-July; also adj. Mex.

4. *Stachys crenata* Raf. SHADE BETONY. Annual or biennial, hirsute; stems usually branched at the base, the branches erect or decumbent, to 3 dm. long; leaves ovate to oblong, to 4 cm. long, obtuse at apex, crenate, truncate to cordate at base, the lower ones with petioles as long as or longer than blade, the uppermost sessile; clusters few-flowered; pedicels 1-2 mm. long; bracts oval to suborbicular, subulate-tipped; calyx 3-5 mm. long; calyx lobes ovate-lanceolate to lanceolate, with subulate tips, mostly shorter than the tube, glabrous beyond the middle; corolla 5-6 mm. long, pink-lavender, pink to blue or rarely white, glabrous except the bearded upper lip, the lobes of the lower lip rounded or the middle one barely emarginate; cocci about 1 mm. long, granular. *S. agraria* Cham. & Schlecht. In shaded rocky or gravelly soils in woods, ravines in prairies, on banks and in open grounds in e., cen. and s. Tex., Feb.-May; also n.e. Mex.

The plant with white corolla and green calyx teeth is segregated as f. *albiflora* Benke.

5. *Stachys tenuifolia* Willd. Perennial, extensively creeping, glabrous or nearly so; the erect simple or branching stems glabrous or at most sparsely hirtellous on the sides, smooth to roughened or hirsute on the angles, to 13 dm. high; leaves with petiole 1-2 cm. long, linear or linear-lanceolate to narrowly ovate, the principal ones 6 cm. broad, glabrous or hirsute on one or both faces, with rounded to subtruncate or tapering base, taper-pointed, sharply dentate to serrate, the middle and lower blades 4 to 11 times as long as their petioles; spike few-flowered, interrupted; calyx 5-6 mm. long, glabrous or bristly along the angles, the lance-attenuate teeth soon outwardly curving; corolla about 1 cm. long, the tube surpassing the calyx, the lower lip drooping and slightly shorter than the tube, the upper lip concave and glandular-pubescent on the back; filaments villous at the base; cocci 2 mm. long, somewhat lustrous. Rich bottomlands, lake shores, muddy bayous, low woods and meadows in e. fourth of Tex., Aug.-Nov.; from N.Y. to Minn., s. to S.C., Tenn., La. and Tex.

6. *Stachys floridana* Shuttlew. Plant spreading by means of elongate sometimes branching tubers; stem to about 4 dm. high, hirsute; leaves elliptic to ovate, serrate or dentate, 1-4 cm. long, the middle and lower blades shorter to slightly longer than their petioles; calyx 5-7 mm. long, puberulent, the lobes lanceolate; corolla 1-1.3 cm. long, the lower

lip as long as the tube; cocci 1.5 mm. long or rarely smaller. In wet sandy soils in s.e. Tex., Mar.-June; from Fla. to Tex., n. to N.C.

16. LAMIUM L.

Annual or perennial herbs; leaves toothed or incised, more or less cordate; flowers small, verticillate in axillary and terminal clusters; calyx tubular-campanulate, usually 5-nerved, 5-toothed, with the sharp-pointed teeth equal or the upper longer; corolla tube dilated above, usually longer than the calyx, the limb 2-lipped; upper corolla lip concave, erect, ovate to oblong, usually entire; lower corolla lip spreading, 3-lobed with the middle lobe emarginate and contracted at the base, the lateral lobes often with a lateral appendage; stamens 4, didynamous, the anterior pair longer; anthers 2-celled, the divaricate sacs often hirsute on the back; style 2-cleft at apex; ovary 4-parted; cocci smooth or tuberculate.

About 40 or more species that are native to the Old World.

1. Upper leaves sessile or clasping 1. *L. amplexicaule*.
 1. Leaves all petioled 2. *L. purpureum*.

1. *Lamium amplexicaule* L. HENBIT, DEAD-NETTLE. Annual or biennial, sparsely pubescent; stems freely branched from the base and often from the lower axils, ascending or decumbent, to 45 cm. high; leaves broadly ovate to reniform or nearly orbicular, truncate to cordate at base, coarsely crenate, the basal leaves slender-petioled and to about 10 mm. wide, the upper leaves sessile or clasping and to about 25 mm. wide; flowers 6 to 10 in axillary and terminal clusters; calyx pubescent, 5-6.5 mm. long, the erect teeth nearly as long as the tube; corolla purple or red, 12-16 mm. long, the tube very slender; lower corolla lip with very small lateral lobes, its middle lobe spotted; upper corolla lip pubescent with reddish hairs; cocci smooth and shining, brown or olivaceous, pebbled or mottled with white, clavate-obovate, trigonous, 2-2.4 mm. long. In cult. areas, among grasses, waste places and along roadsides in most of Tex., flowering throughout the year; a nat. of Eur. naturalized throughout N.A.

2. *Lamium purpureum* L. RED HENBIT, PURPLE DEAD-NETTLE. Annual, sparsely pubescent; stems branched from the base and sometimes from the axils, hollow, decumbent, to about 45 cm. high; leaves deep-green or purplish, setulose, crenate or crenulate; lower leaves slender-petioled, orbicular to broadly ovate, 8-12 mm. long, cordate at base, rounded at apex; upper leaves short-petioled, ovate, usually acutish at apex, cordate at base, 15-25 mm. long; flowers 3 to 6 in a whorl, subtended by a short linear bractlet; calyx purple-angled, hairy, 6-8 mm. long, with lance-attenuate bristly lobes; corolla purple-red, 1-1.6 cm. long, the straight tube rather stout, lateral lobes of the linear lip reduced to short teeth with the middle one spotted, the upper lip densely reddish-pubescent; cocci about 2 mm. long. In waste places and cult. ground in e. Tex., Mar.-Sept.; a nat. of Eur. naturalized in much of N.A.

17. LEONURUS L. MOTHERWORT

About a dozen species native to Eurasia.

1. *Leonurus sibiricus* L. Tall biennial, the softly retrorse-hispid stem to 15 dm. high and leafy; leaves palmately 3-parted, the divisions 2- to 5-cleft or deeply 3- to 7-cleft and incised; flowers in close whorls in leaf axis; calyx 5- to 10-nerved, with 5 nearly equal spiny teeth; corolla strongly bilabiate, purplish, twice as long as the calyx, the upper finely pubescent lip fornicate and entire, the lower 3-lobed lip spreading. In fields, open woods and waste grounds in n.e. to s.-cen. Tex., Apr.-Aug.; a nat. of Eur. that is naturalized from Fla. to Tex., n. to Que., Ky. and Ia.; also trop. Am.

18. LEONOTIS L.

About 40 species, all in Africa.

1. *Leonotis nepetaefolia* A. Br. LION'S-EARS. Annual to about 2 m. high, soft-pubescent, the stout stems simple or branched; leaves petiolate, ovate to ovate-deltoid, to about 12

cm. long, cuneate to subcordate at base, coarsely crenate; the globular flower cluster dense, 4-6 cm. thick; pedicels 1-2 mm. long; calyx curved puberulent, becoming 2 cm. long, 2-lipped, the upper lip longer than the reticulated 10-nerved tube, the 8 to 10 lobes unequal and bristle-tipped; corolla orange-yellow or scarlet, 2-2.5 cm. long, villous-hirsute, 2-lipped, the tube dilated above, curved, the long upper lip erect, the lower lip much shorter than the upper lip and with 3 small lobes; stamens 4, didynamous, ascending, filaments minutely pubescent; cocci 3-angled, smooth, about 3 mm. long. Cult. grounds, roadsides and waste places, mostly in e. and cen. Tex., June-Sept.; from Fla. to Tex., n. to Tenn. and N.C.; nat. of S. Afr.

19. SALVIA L.¹⁶⁷ SAGE

Shrubs or herbs of varied habits, often aromatic; flowers commonly large and showy, in interrupted spikes or terminal heads; calyx bilabiate, usually somewhat laterally compressed, the upper lip commonly entire but sometimes 3-toothed or 3-mucronate, the lower lip usually 2-toothed; corolla mostly blue, red or white, tubular, strongly bilabiate, the upper lip either plane and emarginate or galeate and entire; stamens 2, exerted from the corolla tube beyond the limb or contained within the galea, the connective strongly developed, often more prominent than the filament, bearing a single terminal anther sac, either straight or projected back into the corolla tube, sometimes geniculate; style usually exerted from the galea or beyond the upper lip; cocci smooth.

About 700 species distributed throughout the world but mostly in temperate and tropical regions, centered in South America. The more western *S. Parryi* Gray and *S. chamaedryoides* Cav. have been reported in literature as being in Texas. Also, the Old World *S. aethiopsis* L. has been reported from Texas. It is a coarse woolly herb with flowers subtended by conspicuous persistent sheathing bracts. No Texas specimen has been seen for any of the above species.

1. Calyx with dense ring of hairs in throat; floral bracts equal to or exceeding calyx (2)
1. Calyx without a conspicuous ring of hairs in throat, if somewhat villous the leaves lobed; floral bracts rarely as long as calyx (4)
- 2(1). Stems and leaves stellate-canescens; corolla tube several times the length of the calyx 1. *S. dolichantha*.
2. Stems and leaves setose-hispidulous, not stellate-canescens; corolla tube not or scarcely exceeding the calyx (3)
- 3(2). Nodes below inflorescence mostly 4 to 6; stem with retrorse pubescence continuous on all sides 2. *S. texana*.
3. Nodes below inflorescence 8 to 11; stem lacking retrorse pubescence on the internodes just beneath the leaves 3. *S. Engelmännii*.
- 4(1). Leaves (at least some) deeply divided or lobed (5)
4. Leaves entire, at most crenate or dentate (8)
- 5(4). Leaves mainly in basal rosette, lyrate; corolla blue; distribution in forest region of east Texas 4. *S. lyrata*.
5. Leaves basal and cauline, commonly lobed; corolla usually red or pink; distribution in central and west Texas (6)
- 6(5). Leaves or terminal leaflet 25 mm. wide or more; distribution mainly on Edwards Plateau in west-central Texas 5. *S. Roemeriana*.
6. Leaves or terminal leaflet less than 20 mm. wide; distribution in mountains of Trans-Pecos Texas (7)
- 7(6). Corolla red, the lower lip shorter than the upper lip, the tube somewhat ventricose and rather abruptly dilated just above the calyx 6. *S. Henryi*.
7. Corolla bluish or pinkish with red dots, the lower lip much-exceeding the upper lip, the tube nonventricose and gradually dilated to its mouth 7. *S. summa*.

¹⁶⁷ Adapted partly from Carl Epling in Repert. Sp. Nov. Beih. 110:1-380. 1938-1939; Eula Whitehouse in Field & Lab. 17:151-165. 1949.

- 8(4). Shrubs with distinctly woody stems (9)
 8. Annuals or perennials with herbaceous stems (13)
- 9(8). Corolla red, 25 mm. long or more; calyx 1-2 cm. long (10)
 9. Corolla blue or purplish, less than 15 mm. long; calyx 1 cm. long or less (11)
- 10(9). Leaves typically deltoid-ovate and coarsely crenate; calyx tinged bright red, nearly glabrous, reticulate-veined 8. *S. regla*.
 10. Leaves typically elliptic-oblong and entire; calyx strongly striate, glandular 9. *S. Greggii*.
- 11(9). Flowers in slender open naked racemes; calyx lobes acute-apiculate; corolla tube exceeding the calyx; plant mostly less than 5 dm. high 10. *S. lycioides*.
 11. Flowers in short dense racemes; calyx lobes rounded and obtuse to apiculate; corolla tube included in calyx; plant mostly 10 dm. high or more (12)
- 12(11). Distribution in mountains of extreme west Texas .. 11. *S. pinguiifolia*.
 12. Distribution in Rio Grande Plains and coastal Texas ... 12. *S. ballotaeiflora*.
- 13(8). Leaves linear to narrowly oblong-elliptic or lanceolate, tapered at base (14)
 13. Leaves deltoid-ovate to ovate-lanceolate, rounded to truncate or subcordate at base (19)
- 14(13). Corolla crimson, about 4 cm. long; floral leaves and bracts conspicuous, lanceolate and cuspidate 13. *S. penstemonoides*.
 14. Corolla blue or lavender, occasionally white, less than 3 cm. long; floral leaves and bracts not as above (15)
- 15(14). Calyx oblong-cylindrical, truncated at apex, densely and softly white-tomentose, usually tinged with violet 14. *S. farinacea*.
 15. Calyx narrowly campanulate, distinctly bilabiate, at most shortly pubescent, not tomentose (16)
- 16(15). Leaves linear, at most 5 mm. wide, mostly with entire margins; calyx nearly glabrous, adorned with resinous dots 15. *S. leptophylla*.
 16. Leaves oblong-elliptic to lanceolate, at least some more than 5 mm. wide; calyx more or less minutely pubescent (17)
- 17(16). Corolla 15 mm. long or more, the tube noticeably exerted; calyx puberulent to tomentulose-sericeous 16. *S. azurea*.
 17. Corolla less than 15 mm. long, the tube scarcely exerted; calyx not as above (18)
- 18(17). Calyx minutely hairy on the nerves; widespread .. 17. *S. reflexa*.
 18. Calyx glandular-pilose; rare in western Texas 18. *S. subincisa*.
- 19(13). Flowers in a cylindrical continuous spicate raceme; floral bracts ovate and acuminate, persistent 19. *S. hispanica*.
 19. Flowers in verticils in an interrupted raceme; floral bracts inconspicuous (20)
- 20(19). Calyx truncated at apex, densely and softly white-tomentose, usually tinged with violet 14. *S. farinacea*.
 20. Calyx distinctly bilabiate, minutely pubescent (21)
- 21(20). Corolla deep-red, about 25 mm. long, the tube more than twice as long as the puberulent calyx 20. *S. coccinea*.
 21. Corolla blue, less than 10 mm. long, barely exceeding the calyx; calyx minutely pubescent on the veins (22)
- 22(21). Native perennial; calyx red- or black-dotted, the lobes acuminate; leaves black-dotted on lower surface 21. *S. arizonica*.
 22. Escaped or adventive annual; calyx light-green, the lobes acute; leaves inconspicuously brown-dotted on lower surface 22. *S. tiliaefolia*.

1. *Salvia dolichantha* (Cory) Whiteh. Perennial from a woody taproot, to 45 cm. high; stems herbaceous, commonly unbranched, canescent or cinereous with short stellate hairs

and long setose hairs, with 3 to 5 nodes below the inflorescence; leaves simple, linear, acute, densely stellate-pubescent, the margins revolute, to 85 mm. long and 5 mm. wide; flowers usually 1 or 2 in each axil to form a raceme; floral bracts linear, to about 3 cm. long and 1.5 mm. wide, conspicuous; calyx about 5 mm. long, bilabiate, glandular and setose, the throat closed by a dense band of villous hairs; corolla lavender, 3-4.5 cm. long. *Salviastrum dolichanthum* Cory, *S. texana* var. *canescens* Gray. On chalky outcrops in w. Edwards Plateau and Trans-Pecos, Feb.-May; probably also n.e. Mex.

2. *Salvia texana* (Scheele) Torr. Perennial from a taproot, to 4 dm. high; stems several, herbaceous, more or less branched, densely clothed with long spreading setose-hispidulous and short retrorse setose hairs on all sides; leaves obovate-lanceolate to oblanceolate, obtuse to acute at apex, rugose, with long and short setose hairs, conspicuously glandular-punctate on the lower surface, entire or somewhat dentate, to 6 cm. long and 2 cm. wide; flowers in setose racemes; calyx about 1 cm. long at anthesis, hirsute with spreading bristly hairs, the throat closed by a dense tuft of white hairs; corolla purplish-blue, widely ringent, about 25 mm. long. *Salviastrum texanum* Scheele. Widely distributed in limestone soils and on hills in cen. and w. Tex., Mar.-Oct.; also n. Mex.

3. *Salvia Engelmannii* Gray. Perennial from a woody taproot, to about 4 dm. high; stems often forming dense clumps, slightly hirsute or setose to glabrate, also retrorsely pubescent except on internode face directly below the leaves, commonly unbranched; leaves petiolate, linear-oblongate, entire or the lower ones sometimes denticulate, sparsely setose, conspicuously glandular-punctate, to 8 cm. long and 1 cm. wide; flowers in a compact conspicuous raceme with 2 to 6 flowers at a node; calyx deeply bilabiate, the tube about 5 mm. long, glandular, pubescent, the throat closed by a dense ring of hairs; corolla pale-lavender, widely ringent, to about 4 cm. long. *Salviastrum Engelmannii* (Gray) Briq. Widely distributed on limestone hills of cen. Tex., Apr.-June; endemic.

4. *Salvia lyrata* L. CANCER-WEED, LYRE-LEAF SAGE. Rosulate perennial from a somewhat tuberous root, more or less pilose or hirsute throughout, the scapiform stem to 8 dm. high or more; basal obovate to oblanceolate leaves petioled, membranaceous, the vernal ones sinuate to repand or lyrate-pinnatifid and to 3 dm. long, those of summer and autumn (holding over winter) mostly subentire, usually sparsely strigose-hirsute, often purple-tinged; scape naked or with 1 or 2 pairs of small leaves, simple or with virgate branches; whorls of flowers 3 to 10, becoming distant; floral bracts oblong-linear, mostly shorter than the calyx; calyx campanulate, membranaceous, to 12 mm. long at maturity, the broad upper lip truncate and with 3 widely separated sharp teeth, the lower lip with 2 longer lanceolate cuspidate-pointed teeth; corolla violet or light-blue with darker blue markings, 2-3 cm. long, ampliate-funnelform, exserted, its straight upper lip much shorter than the broad lower one; both forks of connective bearing fertile anthers; cocci fuscous, obovoid, about 2 mm. long. Sandy open woods, meadows and clearings in e. fourth of Tex., Dec.-May; from Fla. to Tex., n. to Conn., N.Y., N.J., Pa., W.Va., O., Ind., Ill., Mo. and Okla.

5. *Salvia Roemeriana* Scheele. CEDAR SAGE. Perennial to about 7 dm. high; stems herbaceous, sometimes straggly, often sparsely hirsute with long spreading hairs; leaves or terminal leaflet roundish or reniform-cordate, coarsely repand-toothed or crenately incised, membranaceous, 2.5-5 cm. wide; lower leaves often with 2 or 3 similar but smaller (sessile or slender-petiolulate) lateral leaflets that are occasionally reduced to dentiform appendages on the petiole; raceme loose and elongated; floral leaves mostly shorter than the pedicels; calyx to 15 mm. long, strongly bilabiate, somewhat pubescent, naked within, its upper lip 3-ristulate or with the middle tooth obsolete, the 2-parted lower lip of triangular-lanceolate cuspidate-acuminate teeth; corolla 25-35 mm. long, deep-scarlet, puberulent, narrowly tubular-funnelform, somewhat arcuate, its spreading lower lip with rounded and obcordate 2-cleft midlobe and scarcely longer than the erect strongly emarginate upper lip; lobes of the style more or less unequal. In cedar brakes, oak woods and in rocky areas, mainly on the Edwards Plateau, rare in the Trans-Pecos, Mar.-Aug.; also adj. Mex.

6. *Salvia Henryi* Gray. Slender perennial to 5 dm. high, soft-pubescent; leaves 3- to 5-foliolate, rarely simple by suppression of the lateral leaflets, the terminal leaflet deeply and irregularly toothed or angulately lobed; flowers 2 at each node; calyx hirsute, ciliate-bearded or somewhat bearded in the sinuses and throat; corolla red, 3-4 cm. long, bilabiate, the tube somewhat ventricose and rather abruptly dilated just above the calyx,

the lower 3-lobed lip shorter than the projecting upper lip; stamen connective bearing fertile anthers at both ends. Rocky areas in canyons and about bluffs in mts. of the Trans-Pecos, Apr.-May; from Tex. to Ariz. and n. Mex.

7. *Salvia summa* A. Nels. Several or many stems from a perennial root, simple or sparingly branched, assurgent, to 3 dm. long, the resinous-dotted herbage finely and densely silky-ciliate and pilose; basal and lower stem leaves often pinnately lobed (occasionally to the midrib), the relatively large terminal lobe coarsely toothed, the other stem leaves ovate to cordate-triangular and variously toothed; flowers showy, singly in the axils of the leaves (two at each node), short-pedicel; calyx 2-lipped to near the middle, the upper lip three-lobed with the middle lobe triangular and shorter and broader than the lance-linear outer ones, the lower lip with two lance-linear lobes similar to and equaling the outer lobes of the upper lip; corolla pilose, bluish to pink with red dots in throat, 35-45 mm. long, more than 3 times as long as the calyx, widely 2-lipped, the nonventricose tube slender but gradually dilated to the spreading lobes, the upper lip concave and nearly or quite entire or abruptly acute, the lower 3-lobed lip noticeably longer than the upper lip; connective shorter than the filament, its branches unequal, both anther cells polleniferous; the unequal subulate stigma lobes well-exserted and surpassing the stamens; cocci smooth. Confined to Guadalupe Mts., in partial shade in canyons and on rocky slopes, Apr.-May; also N.M.

8. *Salvia regla* Cav. MOUNTAIN SAGE. An ornamental much-branched shrub to 2 m. high, the stems and branches puberulent to glabrate; leaves with petioles 5-15 mm. long, broadly deltoid-ovate to subreniform, obtuse to short-acuminate at apex, typically truncate at base, to about 5 cm. long and wide, the margins coarsely crenate, thick-membranaceous, dark-green and glabrous above, hirsute and glandular-punctate beneath; flowers opposite, axillary or in short racemes; pedicels slender, 2-4 mm. long; calyx 1-2 cm. long, bright-red, subinflated, sparsely hirtellous and punctate, the broad lobes obtuse; corolla scarlet, 4-5 cm. long, the tube 2.5-4 cm. long. On rocky wooded slopes and in canyons of Chisos Mts., June-Sept.; also Mex.

An ornamental plant that should receive more attention in landscaping.

9. *Salvia Greggii* Gray. AUTUMN SAGE. Shrubby much-branched perennial to 9 dm. high, glabrous or somewhat farinaceous-puberulent throughout, the slender branches leafy; leaves with petioles 2-5 mm. long, coriaceous, obovate to elliptic, narrowed at base, very obtuse at apex, 1-2.5 cm. long, 1-ribbed, almost veinless, punctate, glabrous, entire to obscurely crenulate; flowers rather few in a naked raceme, the pedicels about 5 mm. long; calyx 1-1.5 cm. long, slightly puberulent or glandular, membranaceous, with at length spreading lips about half the length of the tube; corolla 2.5-3 cm. long, red or scarlet, its tube enlarging and strongly ventricose-gibbous, the throat abruptly contracted under the lower lip which nearly equals the pubescent or glandular-puberulent upper lip (8-10 mm. wide); lower fork of stamen connective oblong-linear; style hairy along the upper side. In rocky soils in cen., w. and s. Tex., Mar.-May; also Mex.

An ornamental plant worthy of cultivation.

10. *Salvia lycioides* Gray. CANYON SAGE. Slender perennial shrub 3-6 dm. high, often straggly, the usually numerous branches sparsely puberulent to glabrate and often slightly glandular above; leaves with petioles 2-5 mm. long, oblong-elliptic to broadly oval, mostly obtuse, 1-3 cm. long, with a strong midnerve, obscurely veined, the margins entire to coarsely crenulate-serrulate, glabrous to minutely hispid-puberulent, glandular-punctate; racemes slender, elongate, interrupted, to 15 cm. long, the flowers opposite; calyx 6-8 mm. long, scabridulous on the ribs, glandular-punctate at maturity, often bluish-tinged, the lobes merely apiculate; corolla blue to indigo-blue, the tube about 1 cm. long, the upper lip 4-4.5 mm. high, the lower lip about 7 mm. long. In canyons, on rocky slopes and on ledges in mts. of the Trans-Pecos, Apr.-Oct.; also N.M. and Mex.

11. *Salvia pinguifolia* (Fern.) Woot. & Standl. ROCK SAGE. Shrub to 15 dm. high, the stems and branches puberulent with whitish hairs; leaves with petioles to 15 mm. long, broadly deltoid-ovate, 2-5 cm. long and about as broad, obtuse at apex, truncate to broadly cordate at base, the margins coarsely crenate-serrate, essentially glabrous, conspicuously glandular-punctate beneath; verticils crowded, in spikes 3-8 cm. long; calyx broadly cornucopiate at maturity, canescent with minute simple appressed hairs and punctate, 6.5-10 mm. long, the lips broadly rounded, the lower lip 3.5-5 mm. wide; corolla lavender-purple, punctate, the tube 5-8 mm. long, the upper lip 4.5-5 mm. high,

the lower lip 4.5-6.5 mm. long; stamen connective 6.5-8 mm. long. Rare in rocky soils in Franklin Mts. at El Paso, Aug.-Sept.; from Tex. to Ariz. and n. Mex.

A plant essentially identical to this species with larger flowers (corolla tube 8.5-10 mm. long) has been segregated as *S. vinacea* Woot. & Standl. It should also occur in the Franklin Mts., as does the present species.

12. *Salvia ballotaeflora* Benth. MEJORANA, BLUE SAGE, CRESPA. Much-branched shrub to 25 dm. high, tomentose-canescens; leaves with petioles to 1 cm. long, broadly ovate-deltoid to oblong-elliptic, obtuse to acute at apex, truncate-cuneate to subcordate at base, 1-4 cm. long, crenate to coarsely dentate, reticulate-veiny, often rugose, glabrate and green above, white stellate-tomentose beneath so as to usually conceal the glands; flowers 1 to 3 in verticils to form short and rather dense simple racemes and in axils of upper leaves; pedicels about 2 mm. long; calyx 5-10 mm. long, tomentulose and glandular-punctate, in fruit broadly funnellform and pendulous, the narrow tube striate-nerved with its 3 subequal lobes broadly ovate and obtuse; corolla bluish or purplish, about 12 mm. long, the throat ventricose, the tube 4-6 mm. long, the upper lip 4-5 mm. high, the lower lip 4.5-6.5 mm. long; stamen connective 5-6 mm. long, hairy opposite its insertion. *S. laxa* Benth. Rocky, sandy or gravelly soils on brushy slopes, thickets and chaparral from Edwards Plateau s. to coast in Tex., Jan.-Oct.; also Mex.

13. *Salvia penstemonoides* Kunth & Bouché. BIG RED SAGE. Perennial, nearly glabrous or below sparsely hirsute; stems to 15 dm. high, leafy to the summit; leaves thickish, linear-lanceolate to oblong-lanceolate, acute to acuminate and mucronate, entire or obscurely denticulate and with ciliolate-scabrous margins, the midnerve prominent beneath; lower leaves 7.5-13 cm. long, with long margined petioles; upper leaves gradually much smaller and becoming essentially sessile; floral leaves and the similar persistent bracts and bractlets of the elongated racemiform or narrowly thyrsoidal inflorescence ovate-lanceolate to linear-lanceolate, cuspidate; cymules subsessile, 3- to 5-flowered; calyx equaled by the hirsute pedicels, campanulate, strongly bilabiate, about 13 mm. long, glandular-puberulent, the upper broad lip truncate and with 3 short and broad cuspidate-mucronate teeth, lower lip 2-parted with its teeth lanceolate and cuspidate; corolla crimson, about 4 cm. long, slightly pubescent, its tube villous-annulate towards the base inside, its large and nearly straight upper lip half the length of the gradually enlarged exerted tube, the middle lobe of the small lower lip concave and entire; style glabrous. In seepage on limestone ledges and banks along streams in cen. Edwards Plateau, June-Oct.; endemic.

14. *Salvia farinacea* Benth. MEALY SAGE, MEALY-CUP SAGE. Perennial herb to 1 m. high, minutely and canescently puberulent or glabrous below, the stems numerous in a cluster; lower leaves with slender petioles to 4 cm. long, linear to ovate-lanceolate or even ovate, obtuse to cuneate or rarely subcordate at base, to about 10 cm. long and 3 cm. wide, usually much smaller, coarsely and irregularly serrate; upper leaves lanceolate or linear-lanceolate, sometimes entire; floral bracts subulate to ovate-lanceolate, mostly caducous; spiciform inflorescence on a long naked peduncle, interrupted, composed of densely many-flowered clusters, finely and (with the calyx) densely and softly white-tomentose (often tinged with violet); calyx oblong-cylindrical and (in age) striate-sulcate, truncated and hairy at apex, the 3 short teeth very broad and obtuse; corolla to 25 mm. long, purple or violet-blue, the tube 6-9 mm. long, the upper lip 3-6 mm. high, with middle division obcordate and 2-lobed. In limestone soils in prairies, thickets, meadows, hillsides and floodplains in most of Tex., mainly in cen. and w. Tex., Apr.-Nov.; also N.M.

Some plants in Brewster County have all their leaves linear. The broad-leaved plants, found especially on the Rio Grande Plains, that are abruptly contracted to a truncate or subcordate base, are segregated as var *latifolia* Shimmers.

15. *Salvia leptophylla* Benth. Perennial herb to about 1 m. high, the erect stems usually forming clumps, typically glabrous but sometimes setose (especially at nodes); leaves linear, attenuate to each end, to 8 cm. long, at most 5 mm. wide, more or less glandular-punctate throughout, entire or rarely remotely denticulate or serrulate; flowers 1 to 3 in bracted verticils in slender interrupted virgate spikes 1.5-3 dm. long, the verticils 1-4 cm. apart; pedicels 2-3 mm. long; calyx to 1 cm. long, glabrous to hispid, resinous-dotted, the lips subequal, the upper lip 7-veined; corolla blue to indigo-blue, the tube 7-11 mm. long, slightly narrowed at base, with or without papillae, the upper lip 3.5-5.5 mm. high, the rounded lower lip 7-10 mm. long and with the midlobe emarginate or

undulate. *S. angustifolia* Cav. and var. *glabra* Gray. In cobbly-gravelly soils in dry washes and stream beds in mts. of the Trans-Pecos, Sept.-Nov.; also Mex.

16. *Salvia azurea* Lam. BLUE SAGE. Erect perennial from a heavy rootstock, to 15 dm. high, cinereous with short curving pubescence, rarely essentially glabrous, the leafy stem simple or branched; leaves to 1 dm. long and 4 cm. wide; lower leaves often lanceolate or oblong, obtuse at apex, tapering to a petiole, denticulate or serrate; upper leaves often linear and entire; inflorescence spiciform, the flower whorls crowded above, tomentulose-sericeous; floral bracts subulate, somewhat persistent; calyx oblong-campanulate, 4.5-10 mm. long, appressed-hispidulous, cleft about one fourth its length, obscurely bilabiate, the broad upper lip entire; corolla deep-blue or rarely white, 15-25 mm. long, with prominently exerted tube, the lower lip sinuately 3-lobed and emarginate. Dry prairies, oak-cedar hills, flats and openings throughout most of Tex., May-Nov.; from S.C. to Fla., w. to Neb., Colo., Ark., Tex. and Mex.

Most of our material belongs to var. *grandiflora* Benth. (*S. Pitcheri* Nutt.) with reflexed hairs on the stem in contrast to the less common var. *azurea* with spreading or ascending hairs on the stem.

17. *Salvia reflexa* Hornem. ROCKY MOUNTAIN SAGE. Annual herb, often bushy-branched, the puberulent to glabrous stem to 7 dm. high; leaves lanceolate to linear-oblong or linear-lanceolate, obtuse to acute at apex, tapering to a slender petiole to 15 mm. long, spreading or reflexed, the larger ones to 5 cm. long and 12 mm. wide, irregularly serrate to entire, glabrescent above; flowers 1 to 3 in a whorl, with winged pedicels 2-3 mm. long, forming a slender interrupted spike; calyx 4-8 mm. long, deeply bilabiate, minutely hairy on the nerves, cleft about halfway to the base, the upper lip entire; corolla blue to whitish, only slightly exerted, the tube 4-4.5 mm. long, the erect upper lip 2.5-3 mm. high, the lower rounded lip 4.5-5 mm. in diameter. *S. lanceolata* Willd., *S. lanceaefolia* Poir. Dry soil in fields, gravel-clay flats, ledges, slopes and rocky soils generally, mostly in w. two thirds of Tex., May-Oct.; from Wisc. to Mont., s. to Ark., Tex., Ariz. and Mex.; adv. eastw.

18. *Salvia subincisa* Benth. Erect annual herb to about 4 dm. high, branched and pubescent above; leaves with petioles to 3 cm. long, oblong-elliptic to lanceolate, acute at apex, narrowly cuneate at base, 2.5-5 cm. long, rarely more than 15 mm. wide, the margins irregularly incised-serrate; flowers solitary or as many as 3 in verticils spaced 1-3 cm. apart; bracts broadly ovate, 3 mm. long, caducous; calyx 4.5-8.5 mm. long, glandular-pilose; corolla tube 4-4.5 mm. long, the upper corolla lip 2.5 mm. broad, the lower corolla lip 7-8 mm. long; lower fork of anther connective bearing its lateral lobe at the middle; style glabrous. Reported from w. Tex., w. to Ariz. and n. Mex.

19. *Salvia hispanica* L. Annual coarse much-branched herb to about 1 m. high, more or less canescent; leaves long-petioled, pale-green, ovate, acute to acuminate at apex, to 12 cm. long and 5 cm. wide, the margins crenate-serrate; flowers in heads on a long-peduncled spiciform inflorescence, with persistent foliaceous broad acuminate bracts; calyx 7.5-11 mm. long; corolla tube about 5 mm. long, the upper corolla lip about 3 mm. wide, the lower corolla lip 3.5-5 mm. long. A nat. of Mex., s. to S.A. and the W.I., introd. in Tex. and elsewhere.

20. *Salvia coccinea* Murr. TROPICAL SAGE, MIRTO, MEJORANA. Perennial with herbaceous or suffrutescent stems to 1 m. high, canescently pubescent to glabrate or hirsute toward the base with long spreading hairs; leaves with petioles 1-3.5 cm. long, membranaceous, veiny, deltoid-ovate, obtuse to acute at apex, truncate to cordate at base, crenate, mostly soft-tomentulose beneath, to 7 cm. long and 5 cm. wide; raceme virgate, the clusters few- to several-flowered and rather distant; pedicels 3-6 mm. long; calyx 6-9 mm. long, crisp-hirtellous, usually tinged with red, the lips of the calyx nearly half that of the tube; corolla usually about 25 mm. long, much-exserted, bright-red or deep-scarlet-red, pubescent or puberulent without, its narrow tube 13-17 mm. long and moderately enlarged above, the upper lip 3.5-5 mm. long, the lower lip twice the length of the upper one from which the stamens protrude; lower forks of the stamen connective long and narrowly linear; style glabrous. In sandy soils in thickets, chaparral, on edge of and in open woods in e. and s. Tex., Feb.-Nov.; from S.C. to Fla. and Tex.; also Mex.

21. *Salvia arizonica* Gray. Perennial herb with creeping woody rootstocks, 3-6 dm. high, glabrous except for 2 puberulent lines down the stem and some long straggly hairs near base of stem; leaves with slender petioles to 1 cm. long or more, deltoid-ovate, obtuse to acute, often abruptly cuneate at base, glabrous, 3-5 cm. long, 15-35 mm. wide,

coarsely and obtusely crenate or serrate, dark-green above, light-green and minutely dark-punctate beneath; inflorescence spiciform and interrupted; clusters several-flowered, at intervals of 1-3 cm.; pedicels about 2 mm. long; floral bracts membranaceous, ovate-lanceolate, caudate, equal to the flowers, caducous; calyx 5-8 mm. long, usually purplish-tinged, dark-punctate, bilabiate to the middle or nearly so, the upper lip subulate and 3-toothed, the lower lip strongly 2-toothed; corolla deep-blue to bluish-lavender or rarely pinkish, the tube 6-8 mm. long and a little exserted, the upper lip about 4 mm. long, the lower lip 6-9 mm. in diameter; style beardless. In rocky soils and among boulders in canyons and in open forests in mts. of the Trans-Pecos, July-Oct.; w. to Ariz.

22. *Salvia tiliaefolia* Vahl. Annual herb to 1 m. high, the stems sparsely crisped-hirtellous above; leaves with slender petioles 2-6 cm. long, broadly triangular-ovate to rhombic-ovate, cordate-truncate to rounded-cuneate at base, obtuse to acute at apex, thin-membranaceous, the primary leaves 3-12 cm. long, sparingly pubescent, dark-green above, sparsely crenate-serrate; verticils 6- to many-flowered, 1-2 cm. apart, in an elongate interrupted simple or branched spiciform inflorescence 15-25 cm. long; pedicels 3-5 mm. long; calyx 4.5-9 mm. long, sparsely subappressed-hispidulous on the ribs; corolla bluish, 6-8 mm. long, the tube 3.5-4 mm. long, the upper lip 1-2 mm. high, the lower lip 2-2.5 mm. long. Introduced as a street weed in Marfa, Presidio Co.; w. to Ariz. and s. to S.A.

20. MONARDA L.¹⁶⁸

MONARDA. HORSEMINT

Erect or ascending herbs or shrubs; leaves odoriferous, ovate to lanceolate or linear, entire or toothed; flowers in a few verticils closely surrounded by bracts to form head-like clusters that form interrupted spikes and/or terminate the branches; calyx tubular, 13- to 15-nerved, usually hairy in the throat; corolla elongated, strongly bilabiate, with a slightly expanded throat; lips linear or oblong, somewhat equal; upper lip erect or arched, entire or slightly notched; lower lip spreading, 3-lobed at the apex, its lateral lobes ovate and obtuse, the middle lobe narrower and slightly notched; stamens 2, elongated, ascending, inserted in the throat of the corolla.

About 20 species extending from Canada to Mexico.

1. Heads solitary and terminal, rarely two; upper lip of the corolla somewhat arcuate but usually erect and in continuation of the tube, the expanded portion of the corolla tube (the throat) as long as or longer than the cylindrical unexpanded part; stamens exserted beyond the upper corolla lip; leaves ovate to ovate-lanceolate, abruptly narrowed to truncate or subcordate at base (2)
1. Heads two or more, forming an interrupted spike; corolla sickle-shaped when viewed from the side because of the markedly falcate upper lip, the expanded portion of the corolla tube usually shorter than the cylindrical unexpanded part; stamens usually not exserted from under the upper corolla lip; leaves elliptic to oblong or even linear, mostly gradually narrowed to base (6)
- 2(1). Corolla pale-rose-purple to whitish, with purple-red dots on lower lip; leafy floral bracts with long-pilose margins; calyx teeth usually conspicuously stipitate-glandular (3)
2. Corolla white to lavender or rose-purple, not spotted; leafy floral bracts with minutely pubescent margins; calyx teeth with or without few sessile glands (4)
- 3(2). Upper lip of corolla bearded at tip, about as long as the tube which is not exserted from the calyx 1. *M. Bradburiana*.
3. Upper lip of corolla not bearded at tip, about half as long as the tube which is long-exserted from the calyx 2. *M. Russeliana*.
- 4(2). Nodes and often lower part of stem long-pilose with spreading hairs; glomerules lax and open so that component branches are readily visible; pedicels 2-5 mm. long; corolla creamy-white 3. *M. Lindheimeri*.
4. Nodes and stems essentially glabrous or with minute appressed or incurved hairs; glomerules tight and compact; pedicels 1-2 mm. long; corolla lavender or purplish, rarely whitish (5)

¹⁶⁸ Adapted mainly from Elizabeth McClintock and Carl Epling in Univ. Calif. Publ. Bot. 20:147-194. 1942; Rainer W. Scora in Univ. of Calif. Publ. Bot. 41:1-59. 1967.

- 5(4). Petioles usually more than 10 mm. long; distribution in east Texas 4. *M. fistulosa*.
5. Petioles usually less than 5 mm. long; distribution in mountains of the Trans-Pecos 5. *M. menthifolia*.
- 6(1). Calyx teeth aristate; floral bracts aristate (7)
6. Calyx teeth deltoid to narrowly triangular-lanceolate, not aristate; floral bracts acute to acuminate but not aristate (9)
- 7(6). Floral bracts similar in shape, oblong, typically reflexed at about the middle to reveal the pubescent purplish inner (adaxial) surface 6. *M. citriodora*.
7. Floral bracts dissimilar, the outer ones broad, becoming progressively narrower inwardly, rarely reflexed, essentially glabrous (8)
- 8(7). Calyx teeth stout and rigid, 4-6 mm. long; bracts elliptic, with strongly raised veins 7. *M. clinopodioides*.
8. Calyx teeth slender and somewhat flexible, 2-3 mm. long; bracts ovate, with slightly raised veins 8. *M. pectinata*.
- 9(6). Perennial or rarely annual herb, the laxly leaved stems usually with elongate internodes; largest leaves mostly more than 8 mm. wide, usually long-tapering to a distinct petiole; floral bracts usually tinged wholly or in part with yellow or white, rarely purplish 9. *M. punctata*.
9. Shrubs or woody perennials, the densely leafy stems with short internodes; largest leaves mostly less than 8 mm. wide, subsessile or shortly petiolate; floral bracts usually tinged with red or purple (10)
- 10(9). Leafy part of stem densely pubescent with long coarse spreading hairs; leaves narrowly lanceolate, coarsely toothed to well below the middle, densely pubescent with long hairs on the lower surface; floral bracts coarsely toothed above middle; along the coast in Aransas, Refugio and San Patricio counties 10. *M. maritima*.
10. Leafy part of stem minutely puberulent with appressed or decurved hairs; leaves linear to very narrowly linear-lanceolate, subentire to sparsely serrulate mostly above the middle, minutely pubescent to somewhat pilose especially below the middle on lower surface; floral bracts entire or rarely remotely toothed; distribution on the Rio Grande Plains and inland in south-central Texas (11)
- 11(10). Herbage cinereous-canescens; leaves linear, obtuse to acute; flowering from January to July; in Rio Grande Plains 11. *M. fruticulosa*.
11. Herbage typically bright-green; leaves linear to narrowly linear-lanceolate, long-acuminate; flowering from late June to October; in south-central Texas (centered in Bastrop-Guadalupe-Gonzales counties) 12. *M. viridissima*.

1. *Monarda Bradburiana* Beck. Stems 3-6 dm. high, usually simple, glabrous or very sparsely villous; leaves sessile or with petioles to 5 mm. long, ovate to deltoid-ovate or triangular-lanceolate, 5-10 cm. long, 2-5 cm. wide, acuminate at apex, rounded to subcordate at base, the margins serrate, sparsely hairy above, villous on the veins beneath; heads 15-25 mm. thick (excluding the corollas); bracteal leaves often tinged with pink or purple, spreading or reflexed, lanceolate; calyx tube 9-14 mm. long, hirsute in the throat, its subulate lobes 2-4 mm. long and often stipitate-glandular; corolla pale-rose-purple to white, dotted with purple, 25-35 mm. long, the upper lip about as long as the tube which is not exerted from the calyx. In wooded areas and thickets, known only from Kerr Co., Apr.-June; from Ala. to Tex., n. to Ind., Ia. and Kan.

2. *Monarda Russeliana* Nutt. Perennial herb 3-8 dm. high; stems slender, simple or sparingly branched from the middle, the median internodes commonly about twice the length of the subtending leaves, all correspondingly elongated and often tortuous as though growing through shrubbery, provided with a few downward curling hairs or entirely glabrous; leaves with petioles less than 5 mm. long, ovate-lanceolate to narrowly lanceolate, 4-6 cm. long, 1-2.5 cm. wide, remotely serrulate to entire, usually thinly hirsute with upwardly directed hairs (especially along the margins); glomerules to 2 cm. broad (excluding the corollas); outer bracts subfoliar, tending to membranous and often purplish tinged, usually reflexed; calyx tube 8-12 mm. long, the subulate teeth

usually about 2 mm. long and bearing stubby capitate glands, the orifice thinly hirsute, the tube puberulent with minute spreading hairs and sprinkled with longer hairs similar to those of the stems; corolla pale-lavender or white, purple-dotted, 2-3.5 cm. long, the tube conspicuously exceeding the calyx, the galea hirtellous or glabrous (not bearded), the throat hirtellous within. *M. virgata* Raf. In gravelly, rocky or sandy soils at edge of woods or in open dry flats or rolling woodlands in n.e. Tex., Apr.-June; from Ky. and Tenn., s.w. to Okla. and Tex.

3. *Monarda Lindheimeri* Gray. Perennial herb 3-6 dm. high; stems simple or branched, glabrous or finely pubescent with downwardly curled hairs or rarely densely covered with stiffish spreading hairs; largest leaves with petioles mostly less than 5 mm. long, prevailing ovate, occasionally ovate-lanceolate, varying from one half to two times as long as the internodes that they subtend, usually borne at the second to the sixth node below the glomerule, 3-5 cm. long, usually 15-25 mm. broad but as much as 4 cm. broad, broadest just above the base, glabrous or minutely puberulent or rarely covered like the stem with dense spreading hairs, serrate or occasionally subentire (particularly the upper pair); glomerules 2-5 cm. broad (excluding the corollas), the component branches visible (at least in older specimens), as much as 12 mm. long, the outer bracts subfoliar and usually reflexed; calyx 9-12 mm. long, puberulent with short spreading hairs, the acuminate teeth 1-2 mm. long, the orifice hirsute within with stiff erect hairs, sometimes bristling with stiff spreading hairs at the base of the teeth; corolla creamy-white, 1.7-3 cm. long, pubescent with short curling hairs, the upper lip comose, the tube 11-19 mm. long, gradually expanded upward, the stamens seated 1-2 mm. within the tube. Usually in sandy soils in and on the edge of woods, in meadows, on slopes and flats in e. fourth of Tex., Apr.-Aug.; also La.

4. *Monarda fistulosa* L. WILD BERGAMONT, LONG-FLOWERED HORSEMINT. Perennial herb to 15 dm. high; stems simple or usually branched, pubescent in the upper parts with downwardly curled hairs, glabrous below, sometimes with longer spreading hairs, rarely glabrous; leaves gray-green, firm (except in deep shade), narrowly triangular-ovate to lanceolate, or sometimes cuneate at base, the straightish serrate-dentate sides tapering to tip, definitely petioled, spreading-hirsute or -villous with long hairs along the nerves beneath, the larger blades to 4 cm. broad and with petioles to 15 mm. long; uppermost leaves and foliaceous reflexed bracts often pink-tinged; glomerules mostly terminal, to 3 cm. broad (excluding the corollas); calyx 7-12 mm. long, puberulent with short spreading hairs, the acuminate teeth usually 1-2 mm. long, the orifice hirsute with stiff erect hairs within, sometimes bristling with similar spreading hairs at the base of the teeth; corolla lavender, 2-3 cm. long, pubescent with short soft curling hairs, the upper lip comose, the tube 15-24 mm. long and gradually expanded upward; stamens seated about 1 mm. within the tube. In dry open woods, old fields, wet meadows and ditches, edge of woods and marshes in e. fourth of Tex., May-July; from Que. and N.E., w. to Minn., s. to Ga., Ala., La. and Tex.

5. *Monarda menthifolia* Grah. Perennial herb 3-10 dm. high; stems simple, rarely branched, pubescent in the upper parts with downwardly curled or spreading hairs and glabrous below or the entire stem glabrous; largest leaves ovate to ovate-lanceolate or lanceolate, 3.5-9 cm. long, 1-3.5 cm. broad, serrate or less often subentire (particularly in the narrow-leaved forms), the upper surfaces usually softly hirtellous with more or less appressed hairs or glabrous, the lower surfaces usually pubescent with curled hairs or sometimes subtomentose; median petioles mostly 2-5 mm. long, rarely as long as 12 mm., usually pubescent with short appressed hairs; glomerules 15-25 mm. broad (excluding the corollas), the outer bracts subfoliar, frequently pink-tinted, reflexed rather than spreading; calyx 7-12 mm. long, occasionally pink-tinted, puberulent with short spreading hairs, the acuminate teeth 1 mm. long, the orifice hirsute within with stiff erect hairs shorter than the calyx teeth, sometimes bristling with similar spreading hairs at the base of the teeth; corolla lavender or rose-purple, 25-38 mm. long, pubescent with short curling hairs, the upper lip comose, the tube 15-25 mm. long, gradually expanded upward, the stamens seated 1-3 mm. within the tube. *M. fistulosa* var. *menthifolia* (Grah.) Fern. Beneath oaks in canyons of mts. in the Trans-Pecos, May-July; from Man. to B.C., s. to Tex., N.M., Ariz. and n. Mex.

6. *Monarda citriodora* Cerv. LEMON BEEBALM, LEMON-MINT, HORSEMINT. Annual or sometimes biennial to 8 dm. high, branching chiefly in the inflorescence or unbranched,

seldom branched at the base, pubescent with small downwardly curled hairs; leaves with petioles to 3 cm. long, lanceolate or oblong, the largest mostly 3-6 cm. long, to 15 mm. wide, thinly and evenly puberulent, glabrate, their margins remotely serrate or subentire and usually ciliate near the base with longer bristles; glomerules 15-35 mm. broad (exclusive of the corollas); outer bracts subfoliar and spreading, less often reflexed; inner bracts oblong, infrequently lanceolate, commonly 6-9 mm. broad, abruptly acuminate to a spinose bristle 2-5 mm. long, usually reflexed from the middle only, thus enclosing the calyces in a bowl-like involucre, their inner surface densely canescent with minute hairs, often purple, the outer surface pubescent, the margins more or less ciliate at least below the middle; calyx tube 6-13 mm. long, puberulent with minute upwardly curled hairs, orifice densely bearded, the aristate teeth 2-7 mm. long, puberulent and more or less hirsute with bristlelike hairs; corolla white or pink, dotted with purple, its tube 7-19 mm. long (including the funnellform throat which is commonly 3-7 mm. long), the upper lip about equal to the lower lip, both shorter than the tube. *M. dispersa* Small. Rather ubiquitous, mostly in sandy loams or rocky soils on slopes and hills or in prairies, meadows and savannahs throughout Tex., Apr.-Oct.; from Mo. and Kan., s. to Tex. and n.e. Mex.; adv. eastw.

Represented in Texas by two variants.

1. Leaves 2-3.5 cm. long, 5-10 mm. wide; bracts not wider than 4 mm.; calyx tube 6-7 mm. long; calyx lobes 2-3 mm. long; unexpanded portion of corolla tube 6-7 mm. long, expanded portion 2-4 mm.; apex of upper corolla lip glabrate; confined to extreme southern Texas var. *parva* Scora.
1. Leaves 2.5-6 cm. long, 8-12 mm. wide; bracts mostly wider than 4 mm.; calyx tube 7-14 mm. long; calyx lobes ciliate; unexpanded portion of corolla tube 7-10 mm. long, expanded portion 4-6 mm.; apex of upper corolla lip with 1-2 mm. long pilosity; widespread var. *citriodora*.

7. *Monarda clinopodioides* Gray. BASIL BEEBALM. Annual, commonly 2-3 dm. high, rarely to 55 cm., sparingly branched at the base or unbranched, the stems pubescent with downwardly curled hairs with which occasional longer bristles may be found; leaves with petioles 4-15 mm. long, mostly oblong, the largest 2-5.5 cm. long, 6-15 mm. wide, rarely more, broadest near the middle, glabrous or puberulent, the margins remotely serrate or entire; glomerules 1.5-3 cm. broad (exclusive of the corollas); outer bracts similar to the leaves but usually ending in a bristle; inner bracts ovate or elliptic, 3-7 mm. broad, abruptly acuminate to a stoutish spinose bristle, the midvein and usually 2 or even 4 to 6 lateral veins well-developed and conspicuous, even costate, the inner surfaces glabrous, the outer surface evenly puberulent but not canescent, the margins regularly pectinate-ciliate with bristlelike hairs; calyx tube 8-9 mm. long, puberulent with small upwardly curled hairs (especially in the lower parts), usually more or less hirsute in the upper parts with bristlelike hairs, the orifice densely hirsute; calyx teeth subulate, stout, stiffish, usually red, 4-6 mm. long; corolla pink or nearly white, its tube 11-15 mm. long (including the funnellform throat that is usually 4-5 mm. long), the upper lip equal to or somewhat longer than the lower and equal to or somewhat shorter than the tube. In sandy or caliche soils and occasionally on granite in meadows, fields, grassy flats and grassy areas in open woodlands mostly in the e. half of Tex., Apr.-June; from Kan. through Okla., s. to Atascosa Co., Tex.

8. *Monarda pectinata* Nutt. PLAINS BEEBALM. Annual to 3 dm. high, usually branched several times from the base, often spreading and globose; stems pubescent with downwardly curled hairs and with occasional longer bristles; leaves oblong to oblong-lanceolate, with petioles to 15 mm. long, the largest 2-5 cm. long and 6-12 mm. wide, glabrous or sparingly puberulent, their margins remotely serrate or subentire; glomerules 15-25 mm. broad (exclusive of the corollas); foliar bracts nearly or quite glabrous, straight and flat, divergent from base, greenish, 2-7 mm. broad, acuminate to a spinose slender bristle, the margins regularly pectinate-ciliate with bristlelike hairs; calyx tube 6-8 mm. long, puberulent with minute upwardly curled hairs or glabrous, very rarely with a few bristlelike hairs, the orifice hirsute, the slender teeth not rigid (2-3 mm. long) and more or less hirsute with bristlelike hairs, often colored; corolla pink or nearly white, its tube 8-14 mm. long (including the funnellform throat which is usually 3-5 mm. long), the lips about equal and usually shorter than the tube. In sandy dryish soils on hills, in

pastures and along streams in w. and n.w. Tex., May-July; from Neb., Colo. and Ut. s. to Tex., N.M. and Ariz.

9. *Monarda punctata* L. SPOTTED BEEBALM, HORSEMINT. Perennial, biennial or annual, rarely as much as 1 m. high, sparingly branched at the base or unbranched below the inflorescence, the stems and leaves variously puberulent or pubescent with curled and sometimes spreading bristlelike hairs; leaves petiolate, lanceolate to oblong-lanceolate or oblong, subtentire to serrate, of varied size, 15-95 mm. long; glomerules 15-25 mm. broad (exclusive of the corollas), subtended by spreading or reflexed yellowish to whitish or rarely purplish entire or remotely serrate bracts that are suborbicular to oblong or lanceolate and usually ciliate on the margins near the base, the outer bracts foliar; calyx 4.5-9 mm. long, commonly finely pubescent; calyx teeth deltoid to narrowly triangular-lanceolate, acute to acuminate or even subspinose at the tip but not at all aristate; corolla whitish, yellowish or rarely pinkish and usually maroon-spotted, the usually falcate upper lip longer than the stamens. Usually in dryish or sandy soils.

Represented by several variants, throughout much of the eastern half of the U.S., of which, according to Scora (1967), the following are found in Texas.

1. Leaves pubescent with long hairs mainly along the midvein on lower surface (2)
1. Leaves pubescent with very short curled hairs on both surfaces (3)
- 2(1). Corolla white to cream-colored, the upper lip marked with pale maroon spots; stem with few usually not spreading bristles var. *lasiodonta* Gray.
2. Corolla deep-yellow, the upper lip marked with deep-dark-maroon spots; stem with spreading bristles var. *arkansana* McCl. & Epl.
- 3(1). Calyx teeth widely deltoid, approximately as long as broad, mostly acute; corollas cream-colored to white or pink; bracts pale- or whitish-green; leaves 3-4 cm. long, 10-13 mm. wide, uniformly pubescent var. *occidentalis* (Epl.)
Palm. & Steyerl.
3. Calyx teeth narrowly deltoid, rarely as broad as long, mostly acuminate; corollas yellowish to white and pink; bracts green to yellowish-green; leaves 4-7 cm. long, 3-25 mm. wide, variously pubescent (4)
- 4(3). Leaves linear-lanceolate to linear, not wider than 8 mm., obscurely petioled; habit predominantly shrubby [= *M. viridissima*] var. *immaculata* (Penn.)
Scora.
4. Leaves elliptic to lanceolate, commonly 8-25 mm. wide, distinctly petioled; habit commonly erect, simple or variously branched (5)
- 5(4). Calyx orifice closed with dense hirsute bristles; corollas yellow, the upper lip distinctly blotched with maroon spots; leaf blades commonly 6-8 cm. long; in Austin and Hays counties var. *Stanfieldii* (Small)
Cory.
5. Calyx orifice glabrous or only slightly bearded; corollas yellow to pale-yellow, the upper lip blotched heavily or only slightly stippled with maroon spots; leaf blades commonly 2.5-7 cm. long (6)
- 6(5). Corolla yellowish with the upper lip blotched heavily with large maroon spots; leaf blades 5-7 cm. long, 10-15 mm. wide, usually as long as or longer than the internodes they subtend var. *intermedia* (McCl. & Epl.) Waterfall.
6. Corolla pale yellow with the upper lip slightly stippled with small maroon dots; leaf blades commonly 5-6 cm. long, 7-13 mm. wide, usually shorter than the internodes they subtend var. *Coryi* (McCl. & Epl.)
Cory.

10. *Monarda maritima* (Cory) Correll. Much-branched shrub to 1 m. high or more; stems densely cottony-tomentose with long spreading white hairs; leaves numerous, crowded on the stems, linear-lanceolate, sessile or short-petioled, tapered to an acute to acuminate apex, more or less conduplicate, to about 4 cm. long and 8 mm. wide, coarsely serrate, subglabrous above, densely long-pubescent beneath with white spreading or twisted hairs; floral glomerules often approximate; outer bracts subtending the glomerules purplish, expanded toward the apex, rounded and toothed, the apical tooth abruptly

deltoid-acuminate and to 2 mm. long, with 5 or more frequently minute glandular-pointed teeth on either side; inner bracts subtending the glomerules narrow, not purplish, long-acuminate, minutely and sparsely toothed or entire, long-ciliate (especially below the middle); calyx 8-9 mm. long, the subulate teeth 1.5-2 mm. long and (at most) puberulent; corolla white. *M. punctata* var. *maritima* Cory. In deep sands in Aransas, Refugio and San Patricio cos., May-Nov.; also Cameron Parish, La.

11. *Monarda fruticulosa* Epl. Diffusely branched shrub, to about 65 cm. high; stems canescent; leaves linear, tapered at base, obtuse to acute at apex, usually 2-3 cm. long, mostly less than 3 mm. wide, prevailingly entire, sometimes toothed above the middle, typically canescent on both surfaces with short fine hairs, often with several long cilia on the basal half; floral bracts light-pink-cerise; calyx 4-5 mm. long, pubescent with short fine spreading hairs, the orifice bearing long silky curled or spreading hairs; calyx teeth about 1 mm. long, narrowly deltoid and acuminate, covered with long silky curled hairs; corolla white or pinkish, often tinged or marked with pink or lavender, usually not dotted, the expanded portion of the tube 4.5-5.5 mm. long, the throat 3-4 mm. long. *M. punctata* var. *fruticulosa* (Epl.) Scora. In deep sand or sandy loam in prairies, mesquite plains, open woods and fields, and on active dunes on the Rio Grande Plains, throughout the year but mostly Jan.-July; endemic but possibly also in adj. Mex.

12. *Monarda viridissima* Correll. Woody perennial to 8 dm. high, with one or more erect puberulent stems that are sparsely branched above; nodes rather short, often less than 4 cm. long; leaves linear to very narrowly linear-lanceolate, tapered at base to a slender petiole to about 1 cm. long, long-acuminate at apex, to about 9 cm. long, and 8 mm. wide or less, usually much smaller, typically bright-green and more or less pubescent, sometimes with a loose tomentum on lower surface along midrib below the middle or with only a few long marginal hairs near the base, rarely essentially glabrous, remotely several-toothed above the middle to subtire; flower whorls as many as 5 per stem; floral bracts broadly ovate to elliptic-lanceolate, acuminate, deep-cerise-pink to purple, the largest to about 2 cm. long, entire or remotely few-toothed above middle; calyx about 6 mm. long, often tinged with purplish-red, with a tuft of white erect hairs within mouth of orifice, the sparsely hirsute subulate teeth mostly about 1 mm. long; corolla white to creamy-white, sometimes tinged or marked with pink, with scattered reddish dots. *M. punctata* var. *immaculata* (Penn.) Scora. Deep sand or sandy soils in open oak and pine-oak forests, s.-cen. Tex. (centered in Bastrop-Guadalupe-Gonzales cos.), late June-Oct.; endemic.

21. BLEPHILIA Raf.

Perennial herbs with erect or ascending sparingly branched stems; leaves similar to those of *Monarda*; flowers numerous, pale-bluish-purple, crowded in axillary or terminal globose whorls; calyx tubular, 13-nerved, naked in the throat, distinctly bilabiate with the upper lip longest, the teeth narrowly triangular to awned; corolla bilabiate, inflated in the throat, villous, the lobes shorter than the tube; upper lip erect, entire; lower lip spreading or deflexed, 3-cleft with the rounded lateral lobes larger than the oblong notched median lobe; stamens 2, exserted.

Only two species. No Texas material has been seen. They are included here based on Fernald's report of their occurrence in the state.

1. Lobes of the lower calyx lip extending beyond the sinuses of the upper calyx lip 1. *B. ciliata*.

1. Lobes of the lower calyx lip not reaching the sinuses of the upper lip 2. *B. hirsuta*.

1. *Blephilia ciliata* (L.) Benth. Stems closely pubescent with recurved hairs, to 9 dm. high; leaves sessile, ovate-oblong to lanceolate, narrowed at base, obtuse to subacute at apex, downy-white beneath, entire to somewhat toothed, 3-6 cm. long; flower heads 3 to 5, continuous; outer bracts ovate, acute, colored, ciliate, as long as the calyx; calyx 7-9 mm. long; corolla pale-blue with purplish spots, 1-1.4 cm. long, pubescent. In dryish woods and open thickets, possibly in n.e. Tex., May-Aug.; from Vt. to Wisc. and Ia., s. to Ga., Miss., Ark., Okla. and (?) Tex.

2. *Blephilia hirsuta* (Pursh) Benth. WOOD-MINT. Stems hirsute with spreading hairs, to 1 m. high or more; leaves long-petioled, ovate to ovate-lanceolate, rounded to cordate at base, acute to subacuminate at apex; flower heads 3 to 5, each separated by a well-developed internode; bracts linear-subulate, shorter than the long-haired calyx; calyx 6-9 mm. long; corolla similar to *B. ciliata*. In moist shaded areas, possibly in n.e. Tex., May-Sept.; from Que. and Vt. to Minn., s. to Ga., Tenn., Ark. and (?) Tex.

22. PERILLA L.

About a half dozen species natives of Asia.

1. *Perilla frutescens* (L.) Britt. BEEFSTEAK PLANT. Coarse aromatic annual, often purple or suffused with purple; stem erect, branching, to about 1 m. high; leaves ovate-oblong to broadly ovate, to 15 cm. long, short-acuminate at apex, coarsely serrate or incised, obtuse to rounded at base but cuneately tapered into the long petiole; flowers small, purple or white, borne singly in the axils of small bracteal leaves to form a loose elongate spikelike 1-sided raceme to 15 cm. long; bracteal leaves oval, folded, rarely greatly enlarged; pedicels 1-3 mm. long; calyx campanulate, 10-nerved, bilabiate, the lips lobed, at anthesis about 3 mm. long, in fruit distended on the lower side and 9-12 mm. long, hairy within; corolla white, tubular, about as long as calyx or slightly longer; corolla lips about equal in length, the 5-lobes broadly rounded; stamens 4, nearly equal, straight, not connivent, about as long as the corolla; cocci globose, reticulated. In damp woods, along open-wooded streams and seepage areas in e. Tex., July-Nov.; from Fla. to Tex., n. to N.E., N.Y., O., Ind., Mo. and Kan.; a nat. of India that locally often becomes a troublesome weed.

The seeds produce an edible oil that is used in commerce.

23. LYCOPUS L. WATER-HOREHOUND. BUGLE-WEED

Perennial mostly stoloniferous herbs resembling *Mentha* but not fragrant; leaves mostly toothed or pinnatifid; floral bracts similar to leaves and much longer than the dense axillary whorls of small mostly white flowers; calyx campanulate to ovoid, 4- or 5-toothed, naked in the throat; corolla more or less campanulate; stamens 2, distant, the upper pair either sterile rudiments or wanting; cocci with thickened margins.

More than a dozen species in the North Temperate regions.

- 1. Mature cocci exceeding the lanceolate to triangular calyx lobes and mostly concealing them1. *L. virginicus*.
- 1. Mature cocci noticeably exceeded by the subulate or cuspidate calyx lobes (2)
- 2(1). Lower and median leaf blades sessile; plant tuberiferous2. *L. asper*.
- 2. Lower and median leaf blades tapering to petioles or to subpetiolar bases; tubers rarely developed (3)
- 3(2). Ridge of cocci entire, relatively soft and corky; lower and median primary leaves typically incised or pinnatifid at least at base3. *L. americanus*.
- 3. Ridge of cocci verrucose to tuberculate; lower and median leaves merely serrate4. *L. rubellus*.

1. *Lycopus virginicus* L. VIRGINIA BUGLE-WEED. Stem obtusely angled, usually puberulent with curved hairs, to about 8 dm. high, rising from a slender (not conspicuously tuberous-thickened) base; stolons filiform, mostly not tuberiferous; leaves dark-green or purple-tinged, ovate to ovate-oblong or elliptic, firm, rather abruptly acuminate at both ends, coarsely toothed, to 15 cm. long and 5 cm. broad; glomerules dense, often seemingly compound, in maturity 8-15 mm. broad, the mature cocci usually concealing the calyces; calyx ovoid-cylindric; corolla tubular, with erect lobes; stamens mostly included; cocci asymmetrical, their summits deeply muricate. Rare in marshy soils and along woodland streams in s.e. Tex., Aug.-Dec.; from Ga. to Tex., n. to N.E., N.Y., O., Ind., Wisc., Minn. and Neb.

2. *Lycopus asper* Greene. Stem strict, rather stout, simple or slightly forking, to about 5 dm. high, from elongate tubers, the internodes spreading-pubescent with long multicellular hairs; leaves sessile, lanceolate to oblong-lanceolate, acute at apex, dark-green, mostly longer than the internodes, appressed to spreading-ascending, scabrous, the larger ones 5-8 cm. long and with 6 to 12 sharp teeth on each side; bracts lanceolate, nearly equaling the glomerules, dilated; calyx teeth triangular to ovate, acuminate, 2-3 mm. long, minutely ciliolate; corolla tube scarcely exceeding the calyx; cocci about 2 mm. long and 1.7 mm. broad, with entire angles and oblique non-tuberculate summit. In wet meadows, marshes and wet shores in the Panhandle, June-Aug.; from Alas. to Calif., e. to Mich., Ill., Mo. and Tex.

3. *Lycopus americanus* Muhl. Stem erect, slender, to about 9 dm. high, glabrous or very sparingly appressed-pubescent with dark hairs, freely stoloniferous, without tubers; leaves petioled, to about 1 dm. long and 3 cm. wide; lower primary leaves incised or pinnatifid (especially at base), glabrous or minutely pubescent on veins beneath, glabrous to scabrous-punctulate above, lanceolate to narrowly ovate or oval; upper leaves lance-attenuate, sinuate to sharply toothed; bracts short; calyx teeth with long subulate tips; corolla white, the tube scarcely or barely longer than the calyx teeth, the filaments exerted; cocci 1-1.5 mm. long, 0.6-1 mm. broad, with entire or barely undulate angles, the dorsal angular face relatively soft and dark, the summit entire. *L. sinuatus* L. Low grounds and wet soils about lakes; along streams and in canyons in n.-cen. Tex. and the Panhandle, Aug.-Nov.; from Nfld. to B.C., s. to Fla., Ala., Miss., Tex., N.M. and Calif.

Those plants whose leaves are scabrous-punctulate on the upper surface are segregated as var. *scabrifolius* Fern.

4. *Lycopus rubellus* Moench. WATER-HOREHOUND. Stem arising from slender stolons and rhizomes to about 12 dm. high; leaves elliptic to elliptic-ovate or -lanceolate, petioled, at most sharply serrate or serrate-dentate, acuminate, to about 15 cm. long and 5 cm. wide; bracts minute; calyx teeth acuminate and sharp-pointed, scarcely subulate-tipped; corolla white, often with purple spots, 3.5-4 mm. long, twice as long as calyx; sterile filaments mostly included; nutlets 1-1.6 mm. long, about 1 mm. broad, firm throughout, the low dorsal angle rounded and the lateral ones often undulate, the summit definitely so. In marshes, swamps, bogs, meadows, ditches, seepage areas and shallow water in e. Tex., Aug.-Dec.; from Fla. to Tex., n. to N.E., N.Y., O., Mich., Ill. and Mo.

We have two variants in this species that are separated as follows:

1. Primary leaves sharply serrate to serrate-dentate; stem glabrous or essentially so; calyx teeth and tube subequal, glabrous, the teeth straight var. *rubellus*.
1. Primary leaves with low and depressed teeth; younger internodes and lower surfaces of leaves pubescent; calyx teeth often with recurving tips var. *arkansanus* (Fresen.)

Benner.

24. MENTHA L. MINT

Odorous perennial herbs with erect or diffuse stems; leaves sessile or petioled, usually punctate; flowers small, in whorls that are axillary or in terminal congested or interrupted spikes, of two sorts as to the fertility of the stamens in most species; calyx campanulate to cylindric, 10-nerved, regular or slightly bilabiate, 5-toothed; corolla pale-purple or whitish, bilabiate, the tube shorter than the calyx, the upper lip entire or emarginate, the lower lip 3-lobed; stamens 4, equal, erect, included or exerted; filaments glabrous; anther sacs parallel; ovary 4-parted; style 2-cleft at the summit; cocci ovoid, smooth.

About 25 species in the North Temperate regions.

1. Flower whorls all distant and in leaf axils; leaves exceeding the whorls 1. *M. arvensis*.
1. Flower whorls forming terminal spikes or some of the lower in the leaf axils and somewhat distant (2)

- 2(1). Plants tomentose or villous-tomentose; leaves sessile 2. *M. rotundifolia*.
2. Plants glabrous or nearly so; leaves more or less petiolate (3)
- 3(2). Leaves short-petioled to nearly sessile; spike slender, more or less interrupted ... 3. *M. spicata*.
3. Leaves all distinctly petioled; spikes thick and mostly dense 4. *M. piperita*.

1. *Mentha arvensis* L. FIELD MINT. Stems stoloniferous, freely branching below or nearly simple, to about 8 dm. high, more or less retrorse-pubescent (especially on the angles); leaves oblong to ovate or lanceolate, rounded at base to a distinct petiole, usually rather closely serrate, minutely pubescent or short-villous, the larger leaves to about 5 cm. long, the upper leaves not much smaller than the lower ones; flower whorls all axillary; calyx pubescent, about 3 mm. long, the triangular-subulate teeth about equaling the tube; corolla pink to violet or white, about twice as long as the calyx, nearly or quite glabrous. Incl. var. *villosa* (Benth.) S. R. Stewart and var. *glabrata* (Benth.) Fern., *M. canadensis* L. In moist rich soils in w. and n.w. Tex., May-Oct.; circumboreal.

2. *Mentha rotundifolia* (L.) Huds. APPLE MINT, ROUNDFOLI MINT. Plant with leafy stolons, the herbage more or less tomentose and viscid; stems mostly erect, to about 15 dm. high, simple or branched; leaves sessile or short-petioled, elliptic to ovate-oblong, subcordate to rounded at base, obtuse at apex, the larger leaves to 5 cm. long, crenate-serrate, more or less rugose-reticulate beneath; flower whorls approximate or the lower especially somewhat distant, forming rather slender spikes to 1 dm. long in fruit; bracts ovate-lanceolate to lanceolate, acuminate, usually shorter than the flowers; calyx campanulate, greenish, velvety, barely 2 mm. long, the subulate teeth about as long as the tube and connivent in fruit; corolla white or pink, about 4 mm. long, puberulent. Along roadsides, in old fields, thickets and waste places in cen. and w. Tex., May-Sept., a nat. of Eur. that has become naturalized in various parts of N.A.

3. *Mentha spicata* L. SPEARMINT. Plant with stolons, glabrous or sparingly pubescent at the nodes; stems usually branched, to 12 dm. high, often purplish; leaves sessile or short-petioled, oblong-lanceolate to ovate-lanceolate, acute to acuminate at apex, obtuse to somewhat rounded to subcordate at base, unequally sharply serrate, the larger leaves 3-6 cm. long; flower whorls in slender terminal leafless spikes often 6-8 cm. long in fruit; bracts subulate-lanceolate, equaling or surpassing the calyx, green, glabrous or ciliate; calyx teeth subulate, about equaling the tube, ciliate on the margins, the inflorescence otherwise glabrous; corolla pale-lavender. In moist fields and meadows, mostly near settlements, in cen. and w. Tex., June-Oct.; a nat. of Eur. that has become naturalized in much of N.A.

4. *Mentha piperita* L. PEPPERMINT. Plant with underground sometimes leafy-bracted stolons; stems erect or somewhat decumbent, branched, to about 8 dm. high, often purplish; leaves petioled, lanceolate to ovate-lanceolate, acute, sharply serrate, dark-green and firm, glabrous or sparsely pubescent on the veins beneath; whorls of flowers in terminal dense or interrupted spikes, to 12 cm. long in fruit; bracts narrowly lanceolate, acuminate, not surpassing the flowers; pedicels elongate; calyx tube glabrous, the teeth about equaling or shorter than the tube and hirsute (sometimes sparingly so), ciliate; corolla glabrous, rose-purple to white. In wet places mostly in w.-cen. Tex., June-Oct.; a nat. of Eur. that has become naturalized in much of N.A.

25. POLIOMINTHA GRAY

ROSEMARY-MINT

Low shrubs, commonly canescent throughout; leaves entire; flowers pink or purple, clustered in the leaf axils; calyx tubular, 13- to 15-striate, barbate in the throat, the 5 teeth equal or nearly so; corolla bilabiate, the upper lip erect and emarginate, the lower lip 3-cleft, the tube equaling or longer than the calyx; stamens 2.

About a half dozen species in Mexico and southwestern United States.

1. Leaves usually linear, sessile; calyx villous-hirsute 1. *P. incana*.
1. Leaves oblong to suborbicular, shortly petioled; calyx tomentulose 2. *P. glabrescens*.

1. *Poliomintha incana* (Torr.) Gray. Shrub usually about 5 dm. high, very much branched, silvery with very close and minute simple hairs, the branches virgate; leaves sessile, linear or the lower sometimes oblong, 1-3 cm. long, densely white-tomentulose with simple hairs, veinless and the midrib obscure, the upper floral leaves usually shorter than the 1 to 3 subsessile flowers in their axils; calyx 15-nerved, oblong or cylindraceous, densely white-villous, 6-7 mm. long, the subulate teeth conspicuous; corolla 1-1.4 cm. long, lavender to whitish with purplish dots on the lower lip, the tube pilose-annulate at the summit. On gypsum hills and flats, eroded slopes and in sandy soil in the Trans-Pecos, Apr.-June; from w. Tex. to Ut. and Ariz; also n. Mex.

2. *Poliomintha glabrescens* Gray. Shrub to about 6 dm. high, puberulent, at length somewhat glabrate, the stems typically with numerous short spreading-ascending lateral leafy branches; leaves linear-oblong, obtuse at apex, rounded at base to a short petiole, 1-2 cm. long, veinless and glabrate above, conspicuously punctate; calyx cylindrical, 4-5 mm. long, commonly purplish-tinged, the short teeth erect; corolla white or lavender with purple dots on the lower lip, about 12 mm. long, the tube pilose-annulate within and about as long as the calyx. In rocky soils in the Trans-Pecos, June-Oct.; also n.e. Mex.

26. HEDEOMA PERS.¹⁶⁹

MOCK PENNYROYAL

Annual to suffrutescent perennial herbs with several erect ascending or decumbent shoots, arising from a woody caudex, usually variously retrorsely pubescent in the upper parts, puberulent below, tomentose with branched hairs in *H. molle*; leaves petiolate or subsessile, membranous to coriaceous, ovate to oblong or elliptical to lanceolate, occasionally rhombic, entire or serrate, nerves prominently raised to inconspicuous, both surfaces variously pubescent, glandular-dotted or punctate; axillary cymes 1- to 15-flowered, usually well-spaced along the axis, occasionally spicate; pedicels usually shorter than the calyces; calyx tubular, 13-nerved, not distended (as in *H. molle* and *H. apiculatum*) or variously gibbous or saccate below, upwardly tapering in *H. Drummondii*, variously pubescent, with a ring of hairs occurring near the summit of the tube to form an annulus that may be included or exerted; upper calyx teeth slightly to strongly connate to form a conspicuous upper lip with the connate portion usually continuous with the tube (the lobes deltoid to subulate, laterally spreading and sharply reflexed to laterally and dorsiventrally convergent to close the calyx orifice, hirsute or hirtellous-ciliate); lower calyx teeth typically subulate, recurved (reflexed in *H. molle*) and exceeding the length of the upper lip, hirsute-ciliate; corolla distinctly bilabiate, the slender or funnelform tube dilated upwardly, glabrous or pubescent within, annulate or not; upper corolla lip ligulate or obcordate in outline, straight or reflexed upwardly, flat or subgaleate, emarginate at its apex; lower corolla lip three-lobed and spreading; stamens 4, consisting of a lower fertile pair and of an upper staminodal pair, the lower pair ascending under the upper lip or somewhat exerted beyond it with the anthers divaricate on a well-developed connective, the upper pair reduced to short naked filaments; style unequally forked at the apex, glabrous; cocci oblong, about twice as long as broad, brown, areolate, glaucous, mucilaginous when moistened.

A genus of about 42 taxa (36 species) concentrated in the American southwest and adjacent areas in Mexico. Five species occur in South America and 2 in eastern and mid-western United States.

1. Suffrutescent perennials, evenly tomentose throughout with profusely branching hairs 1. *H. molle*.
1. Plants of various habits, variously pubescent with simple hairs (2)
- 2(1). Plants caespitose perennials that form dense mats; leaves coriaceous, apiculate; corolla large and showy, to 2 cm. long 2. *H. apiculatum*.
2. Plants annuals or perennials but not caespitose to form mats; leaves and corollas various but not as above (3)

¹⁶⁹ Contributed by Robert S. Irving. See Appendix.

- 3(2). Calyx teeth both laterally and dorsiventrally convergent at maturity and (to varying degrees) closing the calyx orifice; leaves obovate to oblong or linear; annuals or suffrutescent perennials3. *H. Drummondii*.
3. Calyx teeth spreading and reflexed at maturity; leaves and habits various (4)
- 4(3). Leaves serrate; plants perennials (5)
4. Leaves entire or very obscurely crenate; plants annual or biennial (6)
- 5(4). Calyx annulus seated about 1 mm. below the juncture of the upper and lower calyx teeth; leaves obovate-rhombic, the elevated nerves straight and unbranched4. *H. plicatum*.
5. Calyx annulus seated at the juncture of the upper and lower calyx teeth; leaves ovate with the nerves variously raised but usually curved and branched5. *H. costatum* var. *pulchellum*.
- 6(4). Calyx conspicuously and markedly saccate with a broad expanded foliaceous upper lip; leaves linear-lanceolate6. *H. hispidum*.
6. Calyx not as above; leaves ovate (7)
- 7(6). Calyx tube markedly gibbous or saccate below with the width of the distended region over one half the tube's length, the annulus dense; corolla tube abruptly dilated, with the upper lip concave and not upwardly reflexed; plants annual or biennial7. *H. nanum* var. *nanum*.
7. Calyx tube gibbous but with the width of the distended region about a fourth the tube's length, the annulus of a few short hairs; corolla tube not abruptly dilated, small with the upper lip ligulate and reflexed upwardly; plants delicate, ephemeral spring annuals8. *H. acinoides*.

1. *Hedeoma molle* Torr. Robust suffrutescent perennial or semishrub 16-55 cm. high, tomentose-canescens throughout with profusely branching hairs; shoots herbaceous, long-ascending and numerous, with branching almost completely confined to the basal region; leaves petiolate, cinereous or canescent, produced along the entire length of the stems, elliptical to oval, 8.5-22 mm. long, 3-10 mm. wide, the margins entire or obscurely crenate, broadly or narrowly attenuate to base, somewhat acute at apex; axillary cymes occurring along the upper third of the stems, well-spaced or more commonly congested to form a dense spike of cymes, 3- to 15-flowered (typically about 10); calyces 5.2-7 mm. long, the tube radially symmetrical and 4.2-6 mm. long, tomentose with highly branched hairs evenly distributed from the calyx base to the only slightly differentiated upper and lower sets of teeth; upper calyx teeth connate for a third their length to form a short upper lip, the laterally subulate lobes spreading or convergent and erect to sharply outwardly curling; lower calyx teeth subulate, 0.6-1.3 mm. long, erect or reflexed away (not recurved); annulus dense, of unbranched pilose hairs well-exserted from the tube; corolla lavender with maroon markings, 13.2-14 mm. long, pilose-pubescent within but not annulate; upper corolla lip ligulate, about 2.2 mm. long, straight; lower corolla lip 4-5 mm. broad; cocci narrowly oblong in outline, 3 to 5 times longer than wide, about 1.2 mm. long and 0.3 mm. wide. *Poliomintha mollis* (Torr.) Gray. Rocky slopes and ledges in the mts. of the Trans-Pecos, July-Nov.; endemic.

2. *Hedeoma apiculatum* W. S. Stewart. Small suffrutescent perennial forming dense mats; stems herbaceous, arising from a woody caudex, numerous, unbranched, densely clothed with minutely retrorsely curling hairs; leaves crowded in pairs, sessile, coriaceous, lanceolate-elliptic, entire, tapered to a conspicuous apiculate apex, 7-15 mm. long, 1.5-3.5 mm. wide, glabrate; flowers solitary or in 2- or 3-flowered axillary cymes, 3 or 4 cyme-pairs per stem crowded toward the apex; calyx 8.5-9 mm. long, chartaceous; calyx tube tubular-funnelform, slightly or not at all gibbous below, flaring above, 5.5-6.5 mm. long, minutely hispidulous-tuberculate below, glabrous above; upper calyx teeth connate for about a fourth or less their length to form an upper lip 2-2.2 mm. long, the broadly triangulate or deltoid lobes apiculate at their apices and laterally spreading and reflexed, hirtellous-tuberculate-ciliate; lower calyx teeth ascending, narrowly triangular-aristate, about 1.2 mm. wide; annulus ring dense, included within the tube; corolla long and showy, pink, about 20 mm. long, sparsely pubescent within the tube but not annulate;

upper corolla lip broadly obcordate, about 5 mm. long, straight; lower corolla lip very broad and spreading, 9-10 mm. wide; cocci narrowed oblong in outline and somewhat pointed at the apex, about 2 mm. long, 0.7-0.9 mm. wide. Restricted to the Guadalupe Mts., frequent among the rocks of the streamway and canyon sides of the s. fork of McKittrick Canyon and in limestone crevices on adj. Pine Top Mt., July-Aug.; endemic.

3. *Hedeoma Drummondii* Benth. Annual to robust perennial 15-60 cm. high; shoots few to numerous, ascending and/or decumbent, variously branched, densely pubescent or puberulent with the hairs tightly retrorsely curling; leaves usually deciduous at maturity, petiolate or sessile, linear to elliptic-oblong or ovate, 5-14 mm. long, 1-5 mm. wide, entire or obscurely crenate, rounded to attenuated at base, glabrate above, densely pubescent below and on the margins; axillary cymes crowded or well-spaced along the shoots (developing unsymmetrically to 1 side with 2 to 4 flowers per cyme or symmetrically with 1 to 5 flowers per cyme); calyces 5-7 mm. long, the tube 3-5 mm. long, conspicuously saccate for about two thirds its length, the tube above the distended region quickly constricted and tapered into a narrow neck that completely or partially closes the orifice after anthesis, finely pubescent to hoary-pilose (the hairs spreading and/or antrorsely curving); upper calyx teeth not connate or only slightly so, subulate or very narrowly triangulate, 1-1.5 mm. long, to various degrees laterally and dorsiventrally convergent partially or completely to seal the calyx orifice, hirsute to hirtellous-ciliate; annulus very dense, 0.8-1.5 mm. wide, seated about 1 mm. below the juncture of the upper and lower teeth and included; corolla blue or white-marked in the throat, variable in size, 7-15 mm. long, sparsely pubescent in the throat (more densely so in the tube to form a well-defined annulus); upper corolla tip ligulate, straight, concave and subgaleate, 1-5 mm. long; lower corolla lip spreading, 2.5-5 mm. wide; cocci oblong in outline, 1-1.7 mm. long, 0.4-0.6 mm. wide. Limestone soil, roadcuts, bluffs and rocky shoulders nearly throughout though rare in extreme e. Tex., May-Sept.

In Texas represented by the following varieties, broadly overlapping geographically.

1. Plants seldom suffruticose, typically annuals or herbaceous perennials, averaging less than 25 cm. in height; leaves linear or elliptic-oblong, usually more than 3 times longer than wide and commonly 5 times; cymes typically 1- to 5-flowered, developing symmetrically; calyx 5-6 mm. long, hirsute, with the upper and lower teeth convergent completely to close the orifice; corolla blue, 7-11 mm. long
 var. *Drummondii*.

1. Plants not as above (2)

2(1). Plants suffruticose perennials 15-40 cm. tall, branching freely along the lower two thirds of the shoots; leaves elliptic to oblong, usually less than 3 times longer than broad, averaging 8.3 mm. long and 3 mm. wide; cymules 2- to 4-flowered and developing asymmetrically (to one side preferentially); calyx 5-6 mm. long, coarsely hirsute, the upper teeth erect or only slightly laterally spreading and only partially closing the orifice by convergence with the lower teeth; corolla small, 8-10 mm. long, typically white, the tube only slightly dilated upwardly
 var. *serpyllifolium* (Small)

Irving.

2. Plants suffruticose perennials 25-60 cm. tall, branching usually restricted to the base and the upper half of the shoots; leaves elliptic-oblong, less than 3 times longer than broad, averaging 11.7 mm. long and 4 mm. wide; calyx 6-7 mm. long, very coarsely hirsute or hoary-pilose, the upper teeth widely spreading and only slightly onvergent with the lower teeth to close the orifice; corolla large, 10-15 mm. long, white or blue, the tube conspicuously dilated upwardly
 var. *Reverchonii* Gray.

4. *Hedeoma plicatum* Torr. Perennial herb 15-37 cm. high; shoots numerous, ascending or very shortly decumbent, copiously branched toward the base (sparsely so above), hirtellous-pubescent with the hairs retrorsely curving; leaves glabrate above, puberulent below and on margins, elliptic-oval or rhombic, 6.5-10 mm. long, 3-6 mm. wide, the margins conspicuously coarsely serrate, broadly attenuate and shortly petiolate at base, acute at apex, the elevated nerves with secondaries of about 5 subopposite straight or slightly curved unbranched pairs; axillary cymes 3- to 7-flowered, well-spaced along the

upper two thirds of the stems; calyces 4.5-6 mm. long, the tube 3.5-4.3 mm. long and gibbous for about half its length, typically puberulent with short spreading hairs; upper calyx teeth connate about half their length to form a conspicuous upper lip, the narrowly triangulate-lanceolate lobes about 1.5 mm. long and laterally spreading and sharply reflexed, hirsute or hirtellous-ciliate; lower calyx teeth recurved, subulate, hirsute-ciliate; annulus moderately dense, about 0.5 mm. wide and seated at least 1 mm. below the juncture of the upper and lower teeth and included; corolla blue, 7-10 mm. long, short-pubescent in the tube but not annulate; upper corolla lip straight and subgaleate, about 1.5 mm. long; lower corolla lip 2.5-3 mm. wide; cocci oblong in outline, about 1.2 mm. long and 0.6 mm. wide. Pine-oak woodlands in the mts. of the Trans-Pecos, July-Aug.; also Mex.

5. *Hedeoma costatum* Gray var. *pulchellum* (Greene) Irving. Densely tufted perennial to 15 cm. high; shoots numerous, canescent with retrorsely curling hairs, ascending or shortly decumbent, branching in the lower half; leaves ovate or elliptic, 5-10 mm. long, 3-6.5 mm. wide, puberulent to villous above, strigose to villous below, coarsely serrate, rounded or shortly cuneate to a short-petiolate base, sharply acute at apex, the nerves not conspicuously raised; axillary cymes 3- to 5-flowered, typically congested in the upper half of the stems; calyces 6.5-8 mm. long, the tube 4.5-5.5 mm. long, saccate below for about half its length, hoary-villous with hairs spreading or antrorsely curving; upper calyx teeth connate for about a fourth their length, the upper lip 2-3 mm. long with the subulate lobes slightly reflexed-spreading and about 2 mm. long, hirsute-ciliate; lower calyx teeth recurved, subulate, 2-3 mm. long, hirsute-ciliate; annulus dense, about 0.5 mm. wide and seated at the juncture of the upper and lower teeth, included; corolla variable, well-exserted from the calyx or nearly included, 1-2 cm. long, pubescent in the throat and tube but not annulate; upper corolla lip ligulate, slightly upwardly reflexed, about 1.5 mm. long; lower corolla lip 3-4 mm. wide; cocci oblong, about 1.2 mm. long and 0.6 mm. wide. Open rocky limestone outcrops and road embankments of w. Tex., Apr.-June; also N.M. and Mex.

6. *Hedeoma hispidum* Pursh. Coarse annual 9-40 cm. high, densely pubescent with hairs retrorsely curling; stems usually solitary, occasionally numerous, erect or shortly decumbent, the branches absent or few and usually confined to the lower third of the plant; leaves coriaceous with the margins frequently becoming revolute upon drying, linear or linear-elliptic, obtuse, 11-21 mm. long, 1.6-3 mm. wide, entire, attenuated and subsessile at the base, glabrate above, the margins and nerves below typically strigulose; axillary cymes borne along the upper two thirds of the stems or occasionally along its entire length, well-spaced or congested to form a spike of cymes, 3- to 15- (typically 5- to 8-)flowered; calyces highly zygomorphic, 4.9-6 mm. long, the tube 2.8-3.3 mm. long, markedly saccate below for about three fourths of its length, hirsute with the hairs primarily spreading or antrorsely curving; upper calyx teeth connate for about half of their length to form a broad expanded foliaceous upper lip 1.2-2 mm. long (with its margins outwardly flaring and exceeding the width of the tube below), the narrowly triangular acute lobes 0.6-1 mm. long and gradually or sharply reflexed but not markedly laterally spreading, hirtellous-ciliate; lower calyx teeth recurved-subulate, 2-2.5 mm. long, scarcely exceeding the length of the upper lip, hirsute-ciliate; annulus dense, about 0.5 mm. wide and seated at juncture of the upper and lower teeth, slightly exserted from the tube; corolla dimorphic, in the first form scarcely exserted from the calyx, in the second form the corolla 6-7 mm. long and well-exserted from the calyx, both forms glabrous within; upper corolla lip subgaleate, about 1 mm. long; lower corolla lip about 3 mm. wide; cocci oblong, about 1.2 mm. long and 0.6 mm. wide. Loamy soil of prairies and pastures, e. half of Tex.; Apr.-June; to the Atl. Coast, n. to Alta., and e. to N.Y.

7. *Hedeoma nanum* (Torr.) Briq. var. *nanum*. Annual or perennial herb; shoots pilose or hirsute, solitary to numerous, erect to ascending or shortly decumbent, branching at or near the base, typically unbranched above; leaves petiolate, glabrate above, hirtellous below, ovate to oval, variable in dimensions, 5.5-13 mm. long, 2.5-6 mm. wide, entire, broadly rounded to narrowly attenuate at base, broadly acute to narrowly obtuse at apex; axillary cymes 3- to 15-flowered (usually 8 to 10), very dense and compact, well-spaced along the entire length of the shoots or commonly congested to form a dense spike of cymes; calyces 4-5.2 mm. long, the tube 2.5-3.7 mm. long, saccate below for a third to

two thirds the length, the distended region typically wider than half the tube's length, hirsute to hirtellous with hairs spreading; upper calyx teeth connate for slightly less than half their length to form a conspicuous upper lip (1-1.3 mm. long), the narrowly triangulate-lanceolate lobes 0.4-0.7 mm. long and markedly laterally spreading and reflexed, hirtellous-ciliate, the inner face of the lip pubescent as an upward continuation of the annulus; lower calyx teeth subulate, recurved and not conspicuously exceeding the lower lip in length, 1.2-3 mm. long and seated about 0.8 mm. below the juncture of the upper and lower teeth; corolla distinctive, 8-9 mm. long, dark-violet and longitudinally striped, pubescent within the throat in 2 decurrent lines on each side of an adaxial groove, the throat markedly and abruptly dilated; cocci oblong in outline about 1.1 mm. long and 0.5 mm. wide. *H. thymoides* Gray. Rocky limestone outcrops and roadcuts from Del Rio (Val Verde Co.), w. through w. Tex., Apr.-July; Tex., N.M., Ariz., and s. Nev., s. through cen. Mex.

8. *Hedeoma acinoides* Scheele. Delicate ephemeral annual 5-30 cm. high; shoots densely pubescent, nearly lanate, solitary to numerous, erect, ascending or very shortly decumbent, branching restricted to the lower half; leaves with petioles 1-4 mm. long, broadly ovate to elliptic or rhombic-elliptic, 9-25 mm. long, 3.5-8 mm. wide, glabrate, entire or obscurely serrate, rounded to narrowly attenuate at base, obtuse at apex; axillary cymes 3- to 15-flowered and typically congested toward the apices to form a short dense spike of cymes; calyces 5-6.1 mm. long, thin-membranous, the tube relatively long and slender, 4-4.5 mm. long, the lower third distinctly saccate below, glabrate or sparsely hirtellous; upper calyx teeth united for about a third their length to form a small but definite upper lip (0.9-1.2 mm. long), the broadly to narrowly triangulate lobes 0.8-1.1 mm. long and parallel or convergent and only slightly reflexed, densely hirtellous-ciliate; the lower calyx teeth narrowly triangulate to subulate, recurved, 1-1.2 mm. long, only very slightly exceeding the length of the upper lip, hirtellous-ciliate; annulus very weakly represented, consisting of only a few short pilose hairs, about 0.4 mm. wide and seated about 0.3 mm. below the juncture of the upper and lower teeth; corolla 9-13 mm. long, pink, glabrous within, the upper lip ligulate and sharply reflexed backwardly, the lower lip spreading; cocci oblong, about 0.8 mm. long and 0.4 mm. wide. Common in wet years in rocky limestone soil of the e. periphery of the Edwards Plateau and Lampasas Cut Plain, also scatteringly in limestone pockets of the s. Coastal Plain, Apr.-May; also disjunct in Mex.

27. RHODODON EPL.¹⁷⁰

A monotypic genus endemic to Texas.

1. *Rhododon ciliatus* (Benth.) Epl. Annual herbs 15-25 cm. tall; stems erect, branching freely, usually villous in the upper parts with coarse decurved hairs, pubescent below; leaves subsessile, elliptic-oblong, spreading or ascending, 15-20 mm. long, entire, obtuse at apex, rounded-truncate at base, the margins long-ciliate, on both surfaces green and glabrous; axillary cymes 3- to 7-flowered, crowded in the axils of the uppermost leaves to form a compact thyrses 3-6 cm. long; pedicels about half as long as calyx, densely retrorse-pubescent; calyx 15-nerved, slightly distended below, strongly setulose in the lower half with coarse cilia 2 mm. long, the tapering tube 4.5-5 mm. long; calyx teeth connivent or parallel, deltoid-lanceolate, acute, subequal, about as long as the tube, the lower teeth scarcely longer than the upper, strongly annulate at base, the dense annulus exerted, sinuses membranous; corolla pale pink to purple, 5-6 mm. long, the tube strongly villous-annulate near the middle and equal to or shorter than the lower lip; stamens 2, seated at or above the middle of the tube; anthers connate, contained completely within the tube on very short filaments, the sacs widely spreading; style hirtellous-pubescent. *Hedeoma texanum* Cory, *Stachydeoma angulata* Tharp, *S. Duvalii* Tharp. Local in sandy soil, Smith and Robertson cos. to Refugio Co., May-July; endemic.

¹⁷⁰ Contributed by Robert S. Irving.

28. MICROMERIA BENTH.

About 100 species widely distributed.

1. *Micromeria Brownei* (Sw.) Benth. var. *pilosiuscula* Gray. Weak plants with slender sprawling or diffusely spreading sparsely pilose-pubescent stems, to about 4 dm. high or long; leaves petioled, suborbicular to broadly ovate, obscurely crenate, the larger ones to 25 mm. long and 2 cm. wide, thin, glabrous to sparingly pubescent; pedicels filiform, to 15 mm. long; flowers 1 to 3 in axillary one-flowered cymes; calyx sparingly pilose to glabrate, 4-5 mm. long, somewhat villous in the throat; calyx lobes 5, subequal, ovate-deltoid, 1-1.5 mm. long, those of the upper lip abruptly acute or even acuminate; corolla 2-lipped, 7-8 mm. long, pink to lavender-pink or whitish, the tube much-dilated, the mid-lobe of the lower lip about as wide as long and notched; stamens 4, more or less exerted. *M. pilosiuscula* (Gray) Small, *Satureja Brownei* (Sw.) Briq. In swamps, marshes, on stream banks, in woods and along ditches in coastal and s. Tex., throughout year; from Fla. to Tex.

29. SATUREJA L.

More than 100 species mostly in warmer regions of the world.

1. *Satureja arkansana* (Nutt.) Briq. Perennial with odor of pennyroyal, freely stoloniferous, the repent stolons usually with short ovate to elliptic leaves; stems slender, mostly erect, 1-4 dm. high, simple or branching, glabrous or scarcely bearded at the nodes; cauline leaves linear to linear-oblongate, nearly or quite entire, the larger ones to 25 mm. long and 5 mm. wide; cymes few- to many-flowered, their bractlets 3-5 mm. long; calyx tubular, about 3 mm. long, strongly ribbed, sharply toothed; corolla about 1 cm. long, bluish; corolla with straight tube and an inflated throat, distinctly 2-lipped, the upper erect lip flattish and entire or notched, the lower spreading lip 3-parted with the middle lobes usually largest; stamens 4, somewhat ascending; filaments very slender, 4 to 5 times as long as anther; style branches both elongate, strongly curling. *Satureja glabra* (Nutt.) Fern., *S. glabella* (Michx.) Briq. var. *angustifolia* (Torr.) Svens., *Clinopodium glabrum* (Nutt.) O. Ktze., *Calamintha arkansana* (Nutt.) Shinners. On calcareous rocks in ravines, on banks and in barrens in e. and cen. Tex., Apr.-Aug.; from Ont. to Minn., s. to Ark. and Tex.

30. PYCNANTHEMUM MICHX.¹⁷¹

MOUNTAIN-MINT. BASIL

Perennial erect herbs with a pungent mintlike flavor, corymbosely branched above, the floral leaves often whitened; the many-flowered whorls dense, crowded with bracts and usually forming terminal heads or close cymes; calyx about 13-nerved, naked in the throat; corolla short, whitish or purplish, more or less 2-lipped, the lips mostly dotted with purple, the upper lip straight, nearly flat, entire or slightly notched, the lower lip 3-cleft with its lobes all ovate to oblong and obtuse; stamens exerted or included in different flowers; lower pair of stamens rather longer than the upper; anther cells parallel.

About 21 species, mostly in eastern United States.

1. Leaves linear, entire, rarely more than 4 mm. wide ... 1. *P. tenuifolium*.
1. Leaves ovate to narrowly lanceolate, subentire to remotely toothed, more than 5 mm. wide (2)
- 2(1). Floral bracts and leaves green, not whitened; leaves typically narrowly lanceolate 2. *P. clinopodioides*.
2. Floral bracts and often the lower surface of leaves whitened; leaves typically ovate to ovate-lanceolate (3)

¹⁷¹ Ref.: Elizabeth Grant and Carl Epling in Univ. Calif. Publ. Bot. 20:195-239. 1943.

- 3(2). Calyx bilabiate, the upper and lower lips definitely unequal; flowers in irregular corymbs to form glomerules3. *P. albescens*.
 3. Calyx nearly regular, all its teeth essentially equal in length; flowers in tight globose heads4. *P. muticum*.

1. *Pycnanthemum tenuifolium* Schrad. Plant to about 1 m. high, glabrous, forming dense colonies by horizontal roots, usually bearing abundant sterile simple or forking axillary branches; leaves sessile, linear, to about 6 cm. long and 5.5 mm. wide, tapering to apex, firm and sometimes with revolute margins, glabrous or sparsely puberulent, entire; glomerules solitary and terminal, disposed in rather crowded or open corymbs that are simple or made up of several to many secondary corymbs; appressed lance-attenuate bracts and glabrescent lance-subulate calyx teeth 1-2 mm. long, with firm sharp tips; corolla white to pale-lavender, usually purple-spotted; corolla tube 3-4.5 mm. long, pubescent within the throat, the upper lip 2-2.5 mm. tall. *P. flexuosum* of auth. In grassy moist open woods, bogs, savannahs, old fields, meadows and marshes in the e. fourth of Tex., May-Oct.; from Ga. to Tex., n. to N.E., N.Y., Ont., O., Mich., Wisc. and Minn.

2. *Pycnanthemum clinopodioides* T. & G. Plant to about 1 m. high, bearing short leafy branches in the axils of the leaves and branching in the inflorescence; stem pubescent with short curving and longer spreading hairs, the median internodes about equal to the subtending leaves; leaves with petioles 3-6 mm. long, narrowly lanceolate, acuminate, entire or shallowly serrate, the largest 45-95 mm. long and 1-2.5 cm. broad, pale-green, membranous, the upper surface sprinkled with a few hairs, the lower surface pubescent with longer spreading hairs (especially on the midrib and other veins); glomerules terminal, 1 to 3 on a peduncle, disposed in loose corymbs, each subtended by a pair of leaflike bracts that may be canescent, the inner bracts with a few long jointed bristles; calyx pubescent with short hairs, 4-6 mm. long; calyx teeth narrowly deltoid, somewhat acuminate, ciliate with several jointed bristles at the tip, the upper three somewhat connate at the base and about two thirds as long as the lowest pair that are commonly 1-1.5 mm. long; corolla tube rather abruptly narrowed above the middle, 4-5.5 mm. long, the upper lip 3-4 mm. tall; cocci glabrous or sometimes hairy at the tip. *P. pilosum* of auth. Uncommon in and on edge of woods from Mass. along mts. to N.C., with a disjunct station in e. Tex., June-Oct.

3. *Pycnanthemum albescens* T. & G. Plant to 15 dm. high, branching in the upper parts, the branches ascendent or divaricate-ascendent; median internodes about equal to the subtending leaves, the upper internodes pubescent with short curled hairs and bearing a few longer spreading hairs or pubescent with short curled hairs only; leaves with petioles 4-12 mm. long, ovate to ovate-lanceolate or elliptic, all but the lower strongly whitened, paler and minutely pubescent beneath, serrate, 2.5-7 cm. long, 1-2.5 cm. broad, glomerules terminal and solitary or occasionally 2, loose, disposed in irregular corymbs, the branches apparent, canescent; bracts of the involucre foliar and strongly whitened, canescent, rarely with a few longer hairs; calyx canescent throughout with minute appressed hairs, without bristles at the tip, 3.5-5 mm. long, the lower pair of ovate or oblong teeth obtuse and 1-1.3 mm. long, the upper deltoid teeth connate to the middle or more and obtuse; corolla white or lavender, usually spotted; corolla tube gradually enlarged upward, 3-4.5 mm. long, the upper lip 2-4 mm. tall. In low open woods, often along streams, in savannahs and in thicket areas in e. Tex., July-Nov.; from Fla. to Tex., n. to Mo. and e. Okla.

4. *Pycnanthemum muticum* Pers. Plant to 11 dm. high, usually smaller, branching chiefly in the inflorescence, simple below or with a few weak lateral branches; stem minutely hoary-pilose to puberulent, the median internodes usually somewhat longer than the subtending leaves or shorter; leaves subsessile to short-petioled, ovate-lanceolate or narrowly ovate, the largest (usually median) 2.5-8 cm. long and 1.5-4 cm. broad, acuminate at apex, rounded to subcordate at the base, bearing 5 or 6 pairs of lateral veins or more with the intermediate veins apparent, the upper surface glabrous, the lower surface glabrous or pubescent along the veins (especially the midvein), shallowly serrate or rather entire; glomerules solitary and terminal or occasionally 2, subtended by diminished leaflike but canescent velvety bracts; calyx closely pubescent in the upper parts, 3-5 mm. long; calyx teeth narrowly deltoid, somewhat acuminate but scarcely apiculate,

usually about 0.7 mm. long, essentially equal; corolla tube gradually enlarged upward, 3-3.5 mm. long, the upper lip 1.5-2 mm. tall; stamens sometimes normal and about equaling the corolla in length, more frequently minute, scarcely exerted from the throat, apparently nonfunctional. From Me. to Mich. and Ill., s. to Fla. and n.-cen. Tex. where it is very rare in dry open woods, July-Nov.

31. CUNILA L.

DITTANY. STONE MINT

About 15 species from the United States to Uruguay.

1. *Cunila origanoides* (L.) Britt. Perennial herb, woody at base, tufted, corymbosely much-branched, glabrous, to about 4 dm. high; leaves subsessile, ovate to deltoid-ovate smooth, rounded to cordate at base, acute at apex, subentire to irregularly serrate, dotted, 2-4 cm. long; peduncled cymes (axillary) 3- to 9-flowered, usually shorter than the subtending leaf, the flowers mingled with linear bracts about 1 mm. long, the terminal cymes larger and more loosely branched; calyx obconic, regular, about 3 mm. long, strongly 10-nerved, villous in the throat; calyx teeth triangular, equal or nearly so, about a fourth as long as the tube; corolla nearly regular, rose-purple to white, 6-8 mm. long, the tube exerted from the calyx, pubescent, the upper lip erect and shallowly obcordate, the lower lip spreading and about equally 3-lobed; stamens 2, the straight filaments elongate and surpassing the corolla. In dry open woods and thickets in n.-cen. Tex., Sept.-Oct.; from Fla. to Tex., n. to N.Y., Pa., W.Va., O., Ind., Ill., Mo. and Okla.

FAM. 159. SOLANACEAE JUSS.

POTATO OR NIGHTSHADE FAMILY

Herbs, shrubs or trees; leaves alternate or fascicled, sometimes with some opposite, entire to odd-pinnate; flowers in umbels, cymes or panicles, or solitary and lateral, perfect, regular or nearly so, 4- to 6-merous; calyx usually 5-toothed or 5-cleft (rarely 4-toothed), rotate, campanulate or tubular, usually persistent; corolla tubular, campanulate, infundibuliform or rotate, usually more or less 5-lobed, with the lobes valvate or imbricate and usually plicate in bud; stamens usually 5, distinct or slightly united by the anthers; filaments distinct, inserted on the corolla tube alternate with the lobes; anthers opening by slits or pores; styles 1; stigma entire or 2-lobed; ovary superior, usually 2-celled; fruit a berry or capsule.

A family of about 2,100 species in about 90 genera, widely distributed but mostly in the Western Hemisphere.

1. Corolla rotate to broadly campanulate (2)

1. Corolla salverform to funnellform or urceolate (6)

2(1). Calyx accrescent in fruit to invest entirely (or nearly so) the berry (3)

2. Calyx usually not noticeably accrescent in fruit, spiny if investing the fruit (4)

3(2). Calyx becoming much-enlarged and membranaceous-inflated to entirely and permanently enclose the berry, reticulate-veiny; corolla usually lacking tomentose pads on the lower part of lobes 1. *Physalis*, p. 1387.

3. Calyx herbaceous and closely investing the berry or most of it, not angled; corolla with tomentose pads alternating with the filaments . . 2. *Chamaesaracha*, p. 1392.

4(2). Anthers connate into a pointed cone, terminated by a sterile tip, the cells dehiscent longitudinally down the inner face 3. *Lycopersicon*, p. 1393.

4. Anthers not as above (5)

5(4). Anthers typically yellow, much longer than the filaments, connivent or lightly connate around style, the cells opening at apex by pores or slits 4. *Solanum*, p. 1394.

5. Anthers bluish, scarcely longer than the filaments, not connivent around the style, without pores, the cells dehiscent longitudinally . . . 5. *Capsicum*, p. 1399.

- 6(1). Calyx becoming much-enlarged and membranaceous-inflated to enclose the berry, reticulate-veiny; corolla urceolate 6. *Margaranthus*, p. 1399.
6. Calyx not as above (7)
- 7(6). Shrubs or rarely small trees more than 4 dm. high (8)
7. Herbs or suffrutescent perennials less than 3 dm. high, rarely viny (10)
- 8(7). Corolla 35 mm. long or more; petioles 3 cm. long or more 17. *Nicotiana*, p. 1407.
8. Corolla less than 20 mm. long; petioles less than 2 cm. long (9)
- 9(8). Plant native, usually thorny at the nodes, becoming intricate 7. *Lycium*, p. 1400.
9. Plant escaped from cultivation, unarmed, rather open .. 8. *Cestrum*, p. 1402.
- 10(7). Leaves evenly 1- or 2-pinnatisect, the segments entire to somewhat incised; perfect stamens 2 9. *Schizanthus*, p. 1403.
10. Leaves entire or unevenly pinnatisect; perfect stamens more than 2 (11)
- 11(10). Corolla to 1 cm. long (12)
11. Corolla more than 1 cm. long (14)
- 12(11). Plants more or less climbing; leaves ovate-rhombic to suborbicular, 15 mm. long or more; fruit a berry 10. *Salpichroa*, p. 1404.
12. Plants decumbent or creeping; leaves linear to linear-spatulate, to 15 mm. long; fruit a bivalved capsule (13)
- 13(12). Corolla salverform, 7-10 mm. long, the filaments inserted on its upper portion .. 11. *Nierembergia*, p. 1404.
13. Corolla funnellform, about 6 mm. long, the filaments inserted below its middle 12. *Petunia*, p. 1404.
- 14(11). Capsule prickly-armed; calyx circumscissile at base; corolla lobes terminated by abruptly acuminate-attenuate points 13. *Datura*, p. 1404.
14. Capsule unarmed; calyx not circumscissile; corolla lobes not as above (15)
- 15(14). Leaves oblong-spatulate to elliptic-obovate or sometimes lanceolate, tapered at base, to about 1 cm. wide (16)
15. Leaves various, rarely noticeably tapered at base, much more than 1 cm. wide (17)
- 16(15). Plants viscid-pubescent; corolla salverform, purplish 14. *Leptoglossis*, p. 1406.
16. Plants minutely appressed-puberulent, not viscid; corolla funnellform, white or at most lavender-tinged 15. *Bouchetia*, p. 1406.
- 17(15). Leaves with slender petioles, the broadly ovate blade cordate at base and acuminate at apex; corolla tube extended as a crown beyond the spreading lobes of the limb 16. *Nectouxia*, p. 1406.
17. Leaves and corolla not as above 17. *Nicotiana*, p. 1407.

1. *PHYSALIS* L.¹⁷²

GROUND CHERRY

Annual or perennial herbs, ours from a few centimeters to a meter tall, erect or decumbent, some species rhizomatous; leaves petioled, alternate but sometimes 2 or 3 apparently together due to internode reduction; leaf blades usually ovate to lanceolate but varying toward linear, their margins variously toothed (often coarsely and irregularly so) to entire; vestiture various, of long multicellular hairs, or short hairs, or glandular ones, or stellate, or plant nearly glabrous; flowers pedicelled, solitary (in ours) in the leaf axils; flowering calyx 5-lobed or 5-toothed; corollas campanulate to reflexed-rotate, usually yellowish, sometimes blue, rarely white, often with 5 darker contrasting maculations near the base of the limb (these solid in color) or each of several smaller spots, sometimes the maculations not strongly contrasting, sometimes absent; varying quantities

¹⁷² Contributed by U. T. Waterfall.

and sizes of hairs usually present in the corolla tube near the points of filament divergence, sometimes as 5 hairy pads, sometimes these areas more or less glandular; stamens 5; anthers oblong or linear-oblong to ovate, yellow to violet, blue or greenish-blue, or so lined or tinged; filaments filiform to nearly as wide as the anthers; fruiting calyx usually inflated around the 2-carpellate many-seeded often dryish berry, rarely tightly investing it, sometimes invaginated basally.

About 90 species of the New World, mostly in Mexico and Central America, and a few in the Old World.

1. Herbage covered with stellate or variously branched trichomes or with added jointed simple hairs (2)
1. Herbage nearly glabrous or variously hairy but branched hairs (when rarely present) are small, inconspicuous and usually much less numerous than unbranched ones (4)
- 2(1). Hairs stellate 1. *P. viscosa*.
2. Herbage with simple hairs or long-stiped jointed hairs in addition to stellate or 2- or 3-branched ones (3)
- 3(2). Long hairs (1-4 mm. long) on at least the calyx or the base of the stem in addition to a covering of small stellate hairs 2. *P. variovestita*.
3. Indument usually of long bristly hairs, some of which are 2- or 3-divided and sometimes rebranched 3. *P. pumila*.
- 4(1). Anthers (2-) 3-5 mm. long; fruiting calyx slightly 10-angled to 10-ribbed and nearly terete (5)
4. Fruiting calyx 5-angled (10)
- 5(4). Anthers usually yellow, sometimes with a bluish tinge or with bluish edges or lines; plants perennial (6)
5. Anthers blue or violet, sometimes greenish-tinged; plants annual (8)
- 6(5). Flowering pedicels usually 3-8 (-13) mm. long .. 6. *P. hederæfolia*.
6. Flowering pedicels usually 10-15 mm. long (7)
- 7(6). Filaments usually clavate; vestiture villous, at least in part; leaf blades ovate 4. *P. heterophylla*.
7. Filaments not clavate; leaf blades ovate and vestiture sometimes villous only in var. *virginiana*, otherwise the leaf blades are narrower and plants not villous 5. *P. virginiana*.
- 8(5). Corolla maculate; anthers about 3 mm. long, becoming twisted; flowering pedicels usually 3-5 mm. long 7. *P. philadelphica*.
8. Corolla immaculate or inconspicuously spotted; anthers 1-3 mm. long, not twisted or rarely so in *P. acutifolia*; flowering pedicels 5-40 mm. long (9)
- 9(8). Corolla campanulate-funnelform; anthers 1-2.5 mm. long 8. *P. angulata*.
9. Corolla rotate to reflexed-rotate; anthers 2.5-3 mm. long 9. *P. acutifolia*.
- 10(4). Corolla blue (rarely white) 10. *P. lobata*.
10. Corolla yellow (11)
- 11(10). Fruiting calyx glabrous or essentially so 11. *P. cordata*.
11. Fruiting calyx hairy (12)
- 12(11). Fruiting calyx 30-40 mm. long, the lobes tending to be narrowly lanceolate-attenuate 13. *P. turbinata*.
12. Fruiting calyx 15-30 (-32) mm. long, the lobes triangular or ovate-triangular to narrowly lanceolate and subulate-tipped (13)
- 13(12). Fruiting pedicels thick, about 1 mm. in diameter .. 12. *P. subulata* var. *neomexicana*.
13. Fruiting pedicels filiform, less than 0.5 mm. in diameter 14. *P. pubescens*.

1. *Physalis viscosa* L. Erect or decumbent perennial, more or less covered with stellate or several-branched hairs; corolla yellowish, usually dark-maculate; anthers yellow, about 3 mm. long; flowering pedicels 7-35 mm. long; fruiting calyx 15-35 mm. long and 15-28 mm. wide, half-filled by the berry.

Var. *mollis* (Nutt.) Waterfall. Plants erect or spreading; leaves large, ovate, coarsely and irregularly few-toothed, stellate-tomentose beneath; flowering calyces usually 7-10 mm. long; varying in these features into the next variety. Uncommon in and near woods in n.e. Tex., May-July; from adj. Ark. and Okla.

Var. *cinerascens* (Dun.) Waterfall. Plant erect to usually decumbent, more or less covered with stellate or dendritic hairs of varying size and density; leaf blades ovate to rarely reniform, of varying size, their margins toothed, undulate or entire; petioles 1-5 cm. long; corollas yellowish, usually dark-maculate, rotate-reflexed when fully expanded; flowering calyx (3-) 5-7 (-9) mm. long; small-leaved forms have been segregated as *P. mollis* Nutt. var. *parvifolia* Rydb. Throughout Tex. but especially common in the s. and w. areas, Apr. through the growing season, most of the year in s. Tex.; Chis. and Oax. through Okla., barely reaching Ark., Kan. and N.M.

Var. *spathulaefolia* (Torr.) Gray. Leaves spatulate to lanceolate or ovate, the blades basally tapering or gradually extending into winged petioles, those with broad blades and winged petioles approach var. *maritima* (Curtis) Waterfall of the southern Atlantic seacoast. Sandy beaches and plains along the Gulf Coast, a few collections somewhat inland may be intermediates with var. *cinerascens*, mostly Mar.-May but throughout the year; along the coast into La.

2. *Physalis variovestita* Waterfall. Plant erect, from a slender rhizome, with long branched or simple hairs on at least the calyx or the base of the stem in addition to a vestiture of stellate hairs; leaf blades ovate, varyingly dentate (often coarsely and irregularly so), usually more densely vestite on lower surfaces; petioles of principal leaves about equaling the blades in length; corolla yellowish, dark-maculate, 1.5-2 cm. long and 2-3 cm. wide when fully expanded; anthers yellow, about 3 mm. long; flowering calyx about 1 cm. long, about one third divided into ovate or ovate-lanceolate lobes; flowering pedicels 2-3 cm. long, Gulf Coast sands and occasionally inland to Wilson and Gonzales cos., Mar.-June and sometimes later; endemic.

Apparently varying into *P. viscosa* var. *cinerascens*.

3. *Physalis pumila* Nutt. PRAIRIE GROUND CHERRY. Perennial 15-45 cm. tall, branching above; vestiture of jointed hairs 1-2 mm. long, some 1- to 3-branched, spreading at right angles to the stem; leaf blades ovate to ovate-lanceolate or lanceolate, sometimes somewhat rhombic, tapering to a more or less winged petiole; leaf margins usually entire but sometimes slightly and irregularly sinuate-dentate; pedicels 15-30 mm. long; corolla yellowish, only slightly maculate, 12-20 mm. long, 15-25 mm. wide; anthers yellow, 2.5-3 mm. long; flowering calyx 10-15 mm. long, the upper one-third divided into sepal tips; fruiting calyx 3-4 cm. long and 15-20 mm. wide, much-inflated about the berry; fruiting pedicels reflexed, 25-40 mm. long. Prairies and open woods, n.e. Tex. to Brazos Co., Apr.-June; from e. Okla. and adj. Kan. and Mo., barely reaching Ark. and Ill.

4. *Physalis heterophylla* Nees var. *heterophylla sens. lat.* CLAMMY GROUND CHERRY. Stems usually erect from a deeply buried rootstock, 15-90 cm. tall, simple or branched; vestiture of varying proportions of short usually viscid-glandular hairs and long jointed hairs 1-2 mm. long, sometimes with only a few long hairs; leaf blades ovate, usually the principal ones 5-10 cm. long and 3.5-6 cm. wide, with petioles 3-6 cm. long; corollas 10-18 mm. long and 12-18 mm. wide when fully open, yellow, maculate but not always with a strong contrast; flowering calyx 7-12 mm. long, 5-12 mm. wide at the base of the lobes; anthers usually 3-4.5 mm. long, yellow, sometimes tinged with blue or violet; filaments thickened, often as wide as the anthers, sometimes clavate; fruiting calyx usually 2.5-3 cm. long and 2-3 cm. wide, much-inflated about the fruit, with pedicels 1.5-4 cm. long. *P. ambigua* (Gray) Britt., *P. sinuata* Rydb. Various habitats, e. Tex. to Kenedy Co., Apr.-Oct.; widespread in e. U.S. and adj. Can., local in the n. and cen. Rocky Mts. and Great Basin.

Var. *villosa* Waterfall. Stems densely covered with jointed hairs 2-4 mm. long. From Morris Co., in open pine woods, May; also in Ala. and Fla.

5. *Physalis virginiana* Mill. Stems from a deep rhizome; plants from nearly glabrous to long-hairy or with short curved trichomes; leaf blades from ovate and very rarely cordate to linear-lanceolate; corolla 15-25 mm. long, yellow, dark-maculate; anthers 2-4 mm. long, solid-yellow or blue- or violet-tinged; filaments nearly as wide as the anthers to one third as wide; flowering pedicels about equaling the flower to 1.5 times as long; fruiting calyx varyingly inflated about the berry. The variants tend to intergrade.

Var. *virginiana*. The vestiture varies from villous to short and retrorse; leaf blades ovate (rarely cordate) to lanceolate, their margins irregularly and coarsely toothed to sinuate-dentate; corolla usually 15-20 mm. long; anthers yellow, sometimes with a blue or violet tinge. In open woods, adj. prairies and disturbed areas, e. Tex., Apr.-June; from e. U.S. and adj. s. Can., with a few collections from the cen. Rocky Mts.

Forma *macrophysa* (Rydb.) Waterfall. Has larger, much-inflated fruiting calyces 4-5 cm. long and 3-4 cm. broad and anthers light-blue or tinged with light blue. *P. macrophysa* Rydb. Sporadic in e. half of Tex., fruiting material (recognizable condition) from June on; sporadic n.e. to Ind. and Neb.

Var. *texana* (Rydb.) Waterfall. Plant usually several-branched from the base, glabrous or nearly so; principal leaves ovate and usually entire. *P. texana* Rydb. Gulf Coast and occasionally slightly inland, Mar.-June, sometimes in the winter; endemic.

Var. *sonorae* (Torr.) Waterfall. Usually single-stemmed, often branching above; leaf blades usually lanceolate, varying to linear-lanceolate or (rarely) ovate; herbage sparsely covered with short antrorse hairs, sometimes nearly glabrous; calyx often with short antrorse hairs in 10 lines; anthers yellow. *P. longifolia* Nutt., *P. rigida* Pollard & Ball. Open woods, hills, prairies, plains and deserts in most of Tex., May-Sept.; primarily a prairie taxon extending to parts of the e. U.S., the Rocky Mts. and n. Mex.

Var. *hispida* Waterfall. Rhizomatous plant with thick leaf blades varying from ovate-lanceolate to linear-lanceolate; herbage subglabrous, having varying amounts of stiff more or less divergent trichomes about 1 mm. long on at least the flower buds or the margins of the leaves. Plains, often in sand, Panhandle, May-June; from Okla., Kan., Neb. and e. Colo.

6. *Physalis hederifolia* Gray. Erect or spreading from a perennial base, simple or many-stemmed; vestiture various as indicated under the varieties; corollas 10-15 mm. long, yellow or greenish-yellow, maculate (sometimes obscurely so); limb of corolla often reflexed when fully open; anthers usually yellow, 1.5-4 mm. long; flowering calyx about half as long as the corolla, with pedicels 2-7 mm. long; fruiting calyx 10-angled or 10-ribbed, varyingly vestite, 2-3 cm. long and 15-25 mm. wide, on pedicels 1-2 cm. long.

Var. *hederifolia*. Flowering calyx 4-8 mm. wide; anthers 3-4 mm. long; vestiture a varying mixture but including long jointed hairs. *P. Palmeri* Gray. Desert plains and mts., also sandy areas and sometimes open woods, s.w. Tex., sporadic e. to Bastrop and Free-stone cos., Mar.-July, sometimes later; also in N.M., e. Ariz. and adj. Mex.

Var. *puberula* Gray. Herbage with short antrorse hairs only or these mixed with varying amounts of glandular-capitate trichomes. Trans-Pecos, May-Nov.; also n. Mex.

Var. *comata* (Rydb.) Waterfall. Flowering calyces 8-11 mm. wide; anthers 1.5-3 mm. long; leaf blades ovate to rotund, toothed to entire; herbage with long jointed hairs mixed with shorter ones, sometimes viscid or glandular. *P. comata* Rydb. Plains, Dallam Co., June; from w. Neb. to w. Kan. and e. Colo.

Var. *cordifolia* (Gray) Waterfall. Stellate or several-branched hairs present in varying quantities, at least on the margins of the calyx; leaf blades ovate to ovate-lanceolate. *P. Fendleri* Gray. Mts. and plains, s.w. Tex., usually July-Sept.; s.w. U.S.

7. *Physalis philadelphica* Lam. TOMATILLO or MEXICAN GROUND CHERRY. Annual, glabrous to sparsely vestite with short appressed hairs, sometimes long pilosity also present; leaf blades 2-7 cm. long, ovate to ovate-lanceolate, the margins dentate to sinuate-dentate or entire; petiole one half the length of the blade to equaling it; corolla yellowish, maculate, 10-18 mm. wide, rotate-reflexed when fully opened; anthers blue or yellowish with bluish margins, about 3 mm. long, usually strongly twisted after dehiscence; fruiting calyx 10-ribbed, 2-3 cm. long, well-filled by the fruit which may be slightly oily at maturity and is sessile in the calyx; fruiting pedicels 3-8 mm. long. *P. ixocarpa* Hornem. Sporadic, probably as an escape from cult., flowering through most of the growing season; rare in much of the U.S. as a seldom-raised escape, more common in Mex., extending from C.A. and the W.I.

8. *Physalis angulata* L. Annual, 25-100 cm. tall, glabrous or with a few short antrorsely appressed hairs; leaf blades usually ovate to ovate-lanceolate, rarely narrower, usually deeply and irregularly incised-toothed to undulate-toothed or (sometimes) entire, principal ones 5-11 cm. long and 3.5-8 cm. wide, with petioles 4-8 cm. long; flowering calyx (3-) 4-7 mm. long, divided into lobes 1.5-3 mm. long, width 2-4 mm. at base of lobes, on pedicels 5-40 mm. long; corolla yellowish, immaculate or with indistinct spots, 4-12 mm. long, 6-12 mm. wide; anthers bluish or violet, 1-2.5 mm. long, on slender filaments 3-5 mm. long; fruiting calyces 10-angled or 10-ribbed, 20-35 mm. long, 15-25 mm. wide, on pedicels 1-4 cm. long; berry 10-12 mm. in diameter, on a gynobase about 1 mm. long.

Var. *angulata*. Leaf blades ovate to ovate-lanceolate or oblongish, coarsely and irregularly toothed to entire; flowering calyx usually 4-7 mm. long, with lobes 2-3 mm. long; corolla usually immaculate, sometimes with indistinct spots, 6-12 mm. long; anthers 2-2.5 mm. long; fruiting pedicels 2-3 cm. long, shorter than to about equaling the fruiting calyx. *P. ramosissima* Mill., *P. capsicifolia* Dun., *P. Linkiana* Nees. Open woods and disturbed habitats, e. and coastal Tex., summer and throughout much of the year in the s.; from Mex., C.A. and the W.I.

Var. *lanceifolia* (Nees) Waterfall. Differs in having leaf blades lanceolate to linear-lanceolate, corolla usually 4-6 mm. long and anthers usually 1-2 mm. long. *P. lanceifolia* Nees. Occurs in the range of var. *angulata* and w. through s.w. Tex.; from s.w. U.S. and Mex.

Var. *pendula* (Rydb.) Waterfall. Similar to var. *angulata* but leaves sometimes narrower; flowering calyx usually 3 (sometimes 4) mm. long, its lobes about 1 mm. long; fruiting pedicels usually 2-4 cm. long, equaling the fruiting calyx to 3 times its length. *P. pendula* Rydb. E. half of Tex. and rare as far w. as the Panhandle, in valleys and disturbed sites, May-Sept.; extending n.e. to Ill.

9. *Physalis acutifolia* (Miers) Sandw. Annual, usually nearly glabrous, the few appressed hairs short, stiff and flattish; leaf blades ovate-lanceolate to linear-lanceolate, principal ones 4-12 cm. long, with petioles 1.5-7 cm. long; leaf margins usually irregularly and often coarsely toothed; flowering calyx usually 4-5 mm. long, on pedicels 5 to 12 times its length; corolla light-yellow, sometimes with a greenish tinge, rotate with a short tube, 15-23 mm. wide when fully open, with 5 hairy pads on base of limb alternating with stamens; anthers about 3 mm. long, yellow with a blue or blue-green tinge; fruiting calyx usually 2-2.5 cm. long and 1.7-2 cm. wide, on pedicels 2.5-6 cm. long. *P. Wrightii* Gray. Type from "Prairies along the San Pedro River, southwestern Texas;" no other Texas collections seen, summer-fall; Ariz. to Calif. and adj. Mex.

10. *Physalis lobata* Torr. PURPLE GROUND CHERRY. Perennial, branching from the base, spreading or procumbent; indument of varying amounts of crystalline vesicles sparse or abundant enough to give the plant a scurfy appearance; leaf blades ovate-lanceolate to linear-lanceolate, cuneately narrowed to winged petiole, principal ones 4-10 cm. long and 5-30 mm. wide, usually pinnatifid, sometimes sinuate or entire; corollas blue or violet (rarely white), rotate, 1.5-2 cm. broad, with 5 hairy pads alternating with the bases of the filaments; anthers yellow, 1.5-2 mm. long; style twisted and bent to one side; flowering calyx 3-4 mm. long, on pedicels 1-3 (-5) mm. long; fruiting calyx 1.5-2 cm. long, pentagonal-ovoid, inflated, the pedicel 1-2.5 (-3) cm. long; berry spheric-ovoid, 4-7 mm. in diameter. *P. sabaena* Buckl., *Quincula lobata* (Torr.) Raf. Various habitats, w. half of state, Mar.-Sept. or all year in the extreme s.; w. Okla., N.M., Ariz., adj. Mex. to w. Kan. and e. Colo. In f. *lobata* the corolla is blue or violet. Forma *albiflora* Waterfall has white corollas; Val Verde and Brown cos.; otherwise known from one collection in Ariz. and two in Okla.

11. *Physalis cordata* Mill. Annual, appearing glabrous but sparse very short antrorse trichomes usually present, rarely with a few long hairs; leaves ovate to rarely broader, the margins several-toothed; flowering calyx 5-6 mm. long, divided about halfway into narrow acuminate segments; pedicels 4-10 cm. long; corolla yellowish, maculate, hairy in the throat, 5-10 mm. long, 9-22 mm. wide when fully expanded; anthers bluish or greenish-blue, 1.8-3 mm. long, on slightly to densely hairy filaments of similar length; fruiting calyx 5-angled, often somewhat turbinate, basally cordate, glabrous, 25-43 mm. long, 10-15 mm. wide, the narrow teeth acuminate and 7-10 mm. long, sometimes somewhat porrect; berry nearly spheric, 7-15 mm. in diameter; fruiting pedicels 10-25 mm. long. Included on the basis of a Drummond specimen, locality unknown; if present, it should occur along the Gulf Coast, towards the s.; nat. of Mex.

12. *Physalis subulata* Rydb. var. *neomexicana* (Rydb.) Waterfall. Annual, 1-6 dm. tall, spreading-hairy with varying mixtures of short and longer multicellular trichomes (few or many terminating in glands); leaf blades ovate to broadly ovate, sometimes basally oblique, the margins irregularly and usually shallowly toothed, sometimes sinuately so; flowering calyx hairy, 3-4.5 mm. long, upper one half to two thirds divided into lanceolate often subulate-tipped lobes, on pedicels 1.5-3 (-5) cm. long; corolla yellowish, maculate, 6-7 mm. long, 5-11 mm. wide when fully expanded; anthers violet or bluish, (0.3-) 1-1.5 (-2) mm. long, on filaments 2-3 mm. long; fruiting calyx hairy, 5-angled, basally cordate, 2-3 cm. long, 2-2.5 cm. wide, the upper 6-10 mm. divided into narrow teeth, usually subulate-tipped; fruiting pedicels 5-7 (-10) mm. long, reflexed; berry nearly spheric, 6-10 mm. in diameter. *P. neomexicana* Rydb. Jeff Davis and Presidio cos., mts. and adj. areas, June-Oct.; Ariz. and s. Colo. to N.M. and Baja Calif.

The leaves are less deeply and more regularly toothed than in var. *subulata* of Chihuahua and Durango.

13. *Physalis turbinata* Medic. Annual, 15-100 cm. tall; stems spreading-hairy, the trichomes jointed and often gland-tipped; leaf blades ovate, often attenuate-tipped, the margins entire to irregularly (often sinuately) toothed with 1 to 15 teeth on each side; principal leaf blades 5-11 cm. long, 4-8 cm. wide, with appressed jointed hairs in varying abundance on both sides (sometimes restricted to the veins), sometimes some hairs reduced to mere bases; petioles of principal leaves 2-7 cm. long; flowering calyx (3-) 4-6 mm. long, upper one-half to two-thirds divided into narrowly lanceolate lobes; corolla yellowish, maculate, hairy in the throat, 6-12 mm. long, 7-15 mm. wide; anthers bluish, 2-2.8 mm. long, on filaments 3-4 mm. long; fruiting calyx 5-angled, basally cordate, pubescent, 3-4 cm. long, 2-3 cm. wide, its lobes 5-10 mm. long and usually somewhat attenuate; berry nearly spheric, 9-13 mm. in diameter, on a gynophore 1-2 mm. long, it and the lower inner surface of the fruiting calyx sometimes with gland-tipped hairs. *P. barbadosis* Jacq. Open woods, brushland and valleys, e. Tex. and along the Gulf to the lower Rio Grande, July-Nov.; s. U.S., Mex., C.A. and W.I.

Similar to *P. pubescens*, but flowers and fruiting calyces larger, the latter often with longer and narrower lobes, thus resembling *P. cordata* which has glabrous fruiting calyces.

14. *Physalis pubescens* L. TOMATE FRESADILLA, DOWNY GROUND CHERRY. Annual, 8-90 cm. tall, usually villous and sometimes viscid to more or less glabrate; leaf blades ovate, often acuminate, the margins usually irregularly several-toothed or sometimes entire; principal blades usually 4-9 cm. long and 2-4 cm. wide, on petioles 2-7 cm. long; flowering calyx 4-10 mm. long and 3-12 mm. wide at base of lobes, upper 1-4 mm. divided into ovate-deltoid to lanceolate lobes; flowering pedicels 3-6 mm. long; corolla yellowish, dark-maculate, more or less matted-hairy below the maculations, 7-10 (-12) mm. long, 10-15 mm. wide; anthers bluish or violet, 1.5-3 mm. long, on filaments 2-3 mm. long; fruiting calyx 5-angled (usually prominently so), usually soft-hairy, 18-30 mm. long, 13-22 mm. wide, on pedicels 5-13 mm. long; berry 10-18 mm. in diameter, sessile or subsessile on the invaginated calyx base.

Var. *pubescens*. Plants more or less villous; leaf blades usually with 5 to 8 teeth on each side and not translucent. Summer, e. Tex; s. U.S., Mex. and W.I.

Var. *integrifolia* (Dun.) Waterfall. Leaf blades often entire, sometimes with 3 or 4 (rarely more) more or less prominent teeth on each side, usually translucent. Open woods, thickets and adj. areas, e. half of state, Apr.-Nov.; s. U.S., Mex., C.A. and W.I.

2. CHAMAESARACHA GRAY*

FALSE NIGHTSHADE

Perennials with entire to pinnatifid leaves that are decurrent on the petioles; peduncles solitary or in fascicles of 2 to 4 from the axils of the leaves; calyx campanulate, 5-lobed, in fruit somewhat enlarged but not bladdery-inflated, close-fitting to the berry, thin, not angled nor ribbed, faintly (if at all) veiny, open at the mouth, not exceeding the berry; corolla rotate, white or yellowish, often tinged with purple, the limb plicate; stamens inserted near the base of corolla; filaments long and slender; anthers oblong, opening by a longitudinal slit; style and stigma as in *Physalis*; seeds reniform, flattened, rugose-favose or punctate.

About 10 species from western United States to northern South America. This genus

* See Appendix.

is sorely in need of a critical modern revision. There could be as many as six or more entities involved in what we here consider to be three species.

1. Plant more or less stellate-puberulent or stellate-pubescent with sessile or stalked hairs, sometimes with scattered simple hairs and/or glandular hairs, rarely essentially glabrous except for the calyx which is adorned with simple white hairs 1. *C. Coronopus*.
1. Plant densely or rarely sparsely invested with long simple or branched hairs, also typically glandular-viscid (2)
- 2(1). Plants sparsely to copiously villous with weak segmented unbranched hairs; corolla more than 1 cm. in diameter; calyx lobes in anthesis 3 mm. long or more 2. *C. sordida*.
2. Plants densely villous with commonly branching hairs (especially on the calyx and upper part of stem); corolla less than 1 cm. in diameter; calyx lobes about 2 mm. long 3. *C. villosa*.

1. *Chamaesaracha Coronopus* (Dun.) Gray. Plant green, branched and diffuse from a perennial base, varying from subglabrous to densely and finely stellate-pubescent with sessile or stipitate white hairs; leaves sessile or short-petioled, linear to lanceolate, to about 6 cm. long, tapering at the base, more or less sinuately lobed to occasionally subentire or sometimes pinnatifid; peduncle elongated; calyx 4 mm. long, the triangular lobes obtuse to acute; corolla white to greenish or yellowish, usually about 13 mm. in diameter; berry 5-8 mm. in diameter, nearly white, with all but the apex closely invested by the herbaceous calyx. Ubiquitous, mainly in rocky soils and in clays in thickets and on dry plains and mesas in the Edwards Plateau and s. and w. Tex., flowering throughout the year; from Kan. to Ut. and Ariz., s. to Tex. and n. Mex.

As here treated, this is an extremely variable species. Included are essentially glabrous plants whose remnant pubescence is simple, linear-leaved plants with sparse but conspicuous sessile coarse stellate-pubescent, plants with a dense covering of fine pubescence and sometimes also with glandular-pubescent or scattered hairs.

2. *Chamaesaracha sordida* (Dun.) Gray. Plant much-branched from the base, the stems upright to spreading, sometimes forming clumps as much as 7 dm. in diameter, more or less viscid, somewhat cinereous, sparsely to copiously villous with weak segmented unbranched hairs, also usually copiously glandular-puberulent; leaves usually distinctly petioled, ovate to oblong or oblanceolate to obovate, to 1 dm. long and 45 mm. wide, entire to shallowly repand-dentate or pinnatifid; peduncles elongated; calyx shaggy-villous, the triangular acutish lobes 3 mm. long or more; corolla usually about 15 mm. in diameter, white or yellowish, sometimes violet-purplish; berry 5-8 mm. in diameter, with all but the apex closely invested by the herbaceous calyx. *C. coniodes* (Moric.) Britt. Rather ubiquitous on dry plains and mesas, often in limestone, in the w. two thirds of Tex., flowering throughout the year; from Kan. and Colo. to Tex. and s.e. Ariz. and n. Mex.

3. *Chamaesaracha villosa* Rydb. Stems slender and striate, arising from a woody base, sparsely branched, commonly more than 4 dm. long, the entire plant glandular-villous with branching hairs (especially on the calyx and the upper part of the stem); leaves rhombic-ovate to ovate-lanceolate, acute at apex, the margins irregularly crenate or sinuately dentate and decurrent on the slender petiole; peduncle filiform, to about 25 mm. long; calyx lobes triangular, obtuse to acute, about 2 mm. long; corolla yellowish, less than 1 cm. in diameter; berry small, about 5 mm. in diameter, containing about 6 seeds. In gravelly-sandy soil along streams in the s. Trans-Pecos, Mar.-July; also n. Mex.

3. LYCOPERSICON MILL.

Native of the warmer parts of America; several species, the most commonly cultivated is *L. esculentum*.

1. *Lycopersicon esculentum* Mill. TOMATO. Annual or perennial with spreading hairy-pubescent and more or less glandular and strong-smelling, to 15 dm. high or more, the young growth on mature plants erect; leaves odd-pinnate, with small interstitial petiolulate

leaflets, to about 4 dm. long; primary leaflets 5 to 9, stalked, ovate to oblong, to 75 mm. long, acuminate, irregularly incised or toothed, the margins tending to roll inward; flowers 3 to 7, nodding, to about 2 cm. across or more, on jointed pedicels that are reflexed in fruit; calyx 5-parted to base, the lanceolate lobes to 1 cm. long; corolla yellow, the 5 lanceolate lobes recurved-reflexed, a little more than 1 cm. long; anther dehiscent from top to bottom, projected into sharp or narrow sterile tips; fruit a pulpy berry, red or yellow, usually flattened at the ends, to 75 mm. across, the sides often furrowed or angled, seeds numerous. A nat. of w. S.A. that is cult. for its edible fruit.

The plant that occurs in palm groves, thickets and open woodlands in extreme southern Texas, commonly called "cherry tomato," is referable to var. *cerasiforme* (Dun.) Alef. It has thinner leaflets that are mostly smaller and usually less acuminate than in the typical material, the flowers are prevailingly in longer clusters, and the red or yellow regular and globular fruit has fewer cells and is only about 2 cm. in diameter.

4. SOLANUM L.* NIGHTSHADE

Herbs, shrubs or trees of various habit; larger leaves often accompanied by a smaller lateral (rameal) one; peduncles mostly lateral (or becoming lateral) and extra-axillary; calyx and corolla more or less 5-parted or 5-cleft (rarely 4- to 10-parted); corolla plaited in the bud, valvate or induplicate; stamens exserted; filaments usually very short; anthers converging around the style, opening at the tip by two pores or chinks; berry usually 2-celled.

A polymorphous and largely tropical genus of perhaps as many as 1,750 species.

1. Pubescence of lower leaf surface and stems all or chiefly composed of stellate hairs (2)
1. Pubescence of the lower leaf surface and stems composed entirely of simple hairs or lacking; plants without spines or prickles, or with some spines in *S. aculeatissimum* (10)
 - 2(1). Shrub or rarely small tree, without spines or prickles (3)
 2. Annuals or herbaceous perennials, more or less adorned with spines or prickles (4)
 - 3(2). Leaves less than 2 cm. wide, tapered at base, the lower surface thinly pubescent to glabrate; flowers solitary or several in lateral fascicles 1. *S. capsicastrum*.
 3. Leaves more than 3 cm. wide, rounded at base, the lower surface tomentose; flowers borne in definite furcate terminal inflorescences 2. *S. erianthum*.
 - 4(2). Leaves entire to shallowly lobed less than midway to the midvein; calyx merely with stellate pubescence or with 1 to few spines, in fruit not covering the berry (5)
 4. Leaves deepy pinnate to bipinnately lobed; calyx densely spiny, in fruit wholly or partially covering the berry (8)
 - 5(4). Stems and lower leaf surface silvery-canescens because of the dense and close scurflike pubescence, having a velvety appearance .. 3. *S. elaeagnifolium*.
 5. Stems and lower leaf surface not as above, the typically tawny pubescence not so dense (6)
 - 6(5). Anthers 5 mm. long or less; calyx accrescent with age; fruit cherry-red at maturity; confined to extreme southern Texas 4. *S. campechiense*.
 6. Anthers 6 mm. long or more; calyx not noticeably accrescent with age; fruit yellow at maturity (7)
 - 7(6). The 4- to 8-rayed stellate hairs sessile on lower leaf surface; calyx 5-7 mm. long; corolla 2-3 cm. in diameter; anthers 6-8 mm. long; fruit 1-2 cm. in diameter, confined to eastern Texas 5. *S. carolinense*.
 7. At least some of the usually 8- or more-rayed stellate hairs stipitate on lower leaf surface; calyx 8-13 mm. long; corolla 3-5 cm. in diameter; anthers 8-12 mm. long; fruit 2.5-3 cm. in diameter; distribution mostly on prairies west of the eastern pinelands 6. *S. dimidiatum*.

* Ref.: G. Ledyard Stebbins, Jr. and Elton F. Paddock in *Madroño* 10: 70-81. 1949.

- 8(4). Corolla yellow; inflorescence stellate-hairy only, not glandular-villous
 7. *S. rostratum*.
8. Corolla violet or purplish-blue; inflorescence glandular-villous as well as somewhat
 stellate (9)
- 9(8). Anthers unequal, the lowest violet-tinged anther longer and incurved; fruiting
 pedicels erect; berry wholly enclosed by the close-fitting and often adherent calyx
 8. *S. citrullifolium*.
9. Anthers about equal, straight or nearly so, all yellow; fruiting pedicels spreading;
 calyx loosely covering the red berry 9. *S. sisymbriifolium*.
- 10(1). Leaves odd-pinnate, with 3 to 11 leaflets; perennial by subterranean tubers; pedi-
 cels distinctly articulate at or above the middle (11)
10. Leaves simple; annuals or woody perennials (13)
- 11(10). Corolla stellate, white; leaflets typically linear-oblong to oblong-lanceolate;
 pseudostipular and extra-axillary leaves similar to the regular leaves
 10. *S. Jamesii*.
11. Corolla rotate to rotate-stellate, light-purple-lavender to rarely white; leaflets typically
 ovate to ovate-elliptic; pseudostipular leaves semiovate (12)
- 12(11). Plant essentially glabrous; interstitial leaflets minute or lacking; corolla rotate-
 pentagonal 11. *S. leptosepalum*.
12. Plant more or less pilose; interstitial leaflets usually prominent; corolla rotate
 12. *S. Fendleri*.
- 13(10). Leaves deeply pinnatifid, oblong in outline 13. *S. triflorum*.
13. Leaves entire or merely sinuate, sometimes hastately lobed (14)
- 14(13). Plant conspicuously armed with slender yellow spines
 14. *S. aculeatissimum*.
14. Plants unarmed (15)
- 15(14). Plants woody perennials, erect or scandent shrubs; leaves typically oblong or
 hastately ovate (16)
15. Plants annual or rarely a bushy perennial; leaves typically ovate (17)
- 16(15). Leaves broadest at about or above the middle, tapered at base
 15. *S. pseudocapsicum*.
16. Leaves broadest below the middle, not tapered at base
 16. *S. triquetrum*.
- 17(15). Plants conspicuously and persistently villous or hirsute; ripe berries yellow or
 reddish; seeds usually 1.8-2.2 mm. long 17. *S. villosum*.
17. Mature growth of plants sparsely pubescent or glabrous; ripe berries black; seeds
 1.2-1.8 mm. long (18)
- 18(17). Flowers large; corolla 6-11 mm. long from base to apex; anthers 2.6-4 mm. long;
 style exerted about 2 mm. beyond the anthers; stigma very slightly expanded;
 bushy perennial 18. *S. Douglasii*.
18. Flowers smaller; corolla lobes 3-7 mm. long; anthers 1.2-2.6 mm. long; style barely
 exerted beyond the anthers; stigma usually enlarged and capitate (19)
- 19(18). Annual or perennial; leaves firm in texture; calyx lobes all distinct from each
 other, reflexed at maturity; stone cell concretions absent or few, rarely more than 3
 19. *S. nodiflorum*.
19. Strictly annual; leaves thin in texture; calyx lobes unequal in length, some of them
 partly fused, not reflexed at maturity; stone cell concretions always present, usually
 4 to 8 per berry 20. *S. americanum*.

1. *Solanum capsicastrum* Link. FALSE JERUSALEM-CHERRY. Small perennial shrub somewhat resembling *S. pseudocapsicum*, to about 6 dm. high, more or less pubescent throughout with stellate hairs, becoming glabrate; leaves oval to oblong or sometimes slightly ovate, about 6 cm. long and 15 mm. wide, narrowed at the base, obtuse at apex,

the margins entire or only slightly repand; pedicels about 7 mm. long; flowers small, white, less than 15 mm. in diameter; fruit orange-red or scarlet, about 13 mm. in diameter. A nat. of S.A. that is occasionally cult. and becomes an escape in s. Tex.

2. *Solanum erianthum* D. Don. POTATO TREE, SALVADORA. Shrub or small tree to 3 m. high, very soft velvety-tomentose throughout with stellate hairs; leaves with a petiole to 4 cm. long, ovate to ovate-elliptic or elliptic, rounded at base, acute to acuminate at apex, to 3 dm. long, entire, very hoary on lower surface; peduncle usually terminal, erect, rather long and stout, bearing a many-flowered cyme; calyx lobes ovate, obtuse, ciliate; corolla white, 15-18 mm. in diameter, the ciliate lobes ovate to ovate-oval and acute; anthers oblong; ovary woolly; berry globose, 1-2 cm. in diameter, yellow. *S. verbascifolium* of auth. In open woods and thickets in extreme s. Tex. n. to Kenedy Co., Apr.-Oct.; also in s. Fla. and throughout trop. and subtrop. Am.

3. *Solanum elaeagnifolium* Cav. SILVER-LEAF NIGHTSHADE, BULL-NETTLE, TROMPILLO, WHITE HORSE-NETTLE. Perennial to about 1 m. high, with deep running rootstocks, silvery-canescens all over by the dense and close scurflike pubescence that is composed of many-rayed stellate hairs; stem often woody at base; prickles small and acicular, copious to very sparse; leaves with a petiole to 5 cm. long, oblong to linear or oblong-lanceolate, to about 15 cm. long, usually tapered at base, mostly obtuse, entire to sinuate-repand; cymes at first terminal, short-peduncled, few-flowered; pedicels rather long, recurved or reflexed in fruit; calyx 5-angled, with slender lobes fully as long as the tube; corolla violet or rarely white, lightly 5-lobed, 2-2.5 cm. in diameter, the lobes triangular-ovate; ovary white-tomentose; berry globose, to about 15 mm. in diameter, yellowish or eventually black. *S. texense* Engelm. & Gray, *S. Roemerianum* Scheele. In dry sterile soils in open woods, prairies, waste places and disturbed soils throughout most of Tex., Mar.-Oct.; from Mo. and Kan., s. to La., Tex., Ariz. and adj. Mex.; adv. elsewhere in the U.S.

The white-flowered plant is known as f. *albiflorum* Cockll.

4. *Solanum campechiense* L. Herbs to 6 dm. high, annual, adorned with stellate pubescence and spines to 6 mm. long; stems herbaceous, branched, greenish, the branches spreading; leaves oblong, somewhat 5-lobed with the lobes more or less repand-dentate, more or less cordate at base, to 12.5 cm. long (including the petiole), about 65 mm. wide; raceme few-flowered, on a peduncle to about 15 cm. long, usually much less; calyx cyathiform, 6-8 mm. long, with ovate-lanceolate acute lobes, accrescent with age; corolla pale-violet, about 2 cm. in diameter; anthers 4-5 mm. long; berries cherry-red, 1-1.5 cm. in diameter. In extreme s. Tex., summer-fall; also Mex. and W.I.

5. *Solanum carolinense* L. CAROLINA HORSE-NETTLE, BALL-NETTLE. Coarse erect branching perennial to about 1 m. high, with a creeping subterranean rhizome, spiny and loosely pubescent throughout with 4- to 8-rayed sessile stellate hairs; leaves with a petiole to 3 cm. long, ovate to ovate-elliptic in outline, rounded at base, to 12 cm. long, greenish, typically with several large teeth or shallow lobes on each side, more or less spiny along the main veins; inflorescence several-flowered, elongating at maturity to form a simple racemiform cluster; calyx 5-7 mm. long, the lobes lance-acuminate; corolla pale-violet to white, 2-3 cm. in diameter; anthers 6-8 mm. long, equal; fruit globose, yellow when mature, 1-2 cm. in diameter. In fields, open woodlands and waste places, generally, mostly in sandy or light soils, confined to e. Tex., Apr.-Oct.; from Tex., n. to Minn. and e. to the Atl. Ocean.

The white-flowered plants are known as f. *albiflorum* Benke.

6. *Solanum dimidiatum* Raf. WESTERN HORSE-NETTLE. Plant perennial, to about 1 m. high, with deep running rootstock, cinereous with a somewhat furfuraceous stellate pubescence composed of 9- to 12-rayed frequently stipitate hairs; prickles small, subulate, scanty along the stem and midribs of leaves or sometimes nearly wanting; leaves with short stout petioles, ovate in outline, the base broadly rounded to truncate or somewhat cordate, to about 15 cm. long, some of the stellate hairs on lower surface distinctly stipitate, typically sinuately 5- or 7-lobed, the lobes entire or undulate and unarmed; cymes at first terminal, laxly 2- or 3-divided; pedicels recurved or reflexed in fruit; calyx lobes often 6, short-ovate with a long abruptly acuminate apex, 8-13 mm. long; corolla bluish-purple to violet or rarely white, 3-5 cm. in diameter, its 5 lobes broadly ovate; anthers lanceolate to linear-lanceolate, 8-12 mm. long; berries globose, 2.5-3 cm. in diameter, pale-yellow when mature. *S. Torreyi* Gray. Mostly in prairies and sandy soils throughout Tex. except in extreme e. and w., May-Oct.; from Kan., Mo. and Ark., s. to Tex.

The white-flowered plant is known as f. *album* (Waterfall) Correll.

7. *Solanum rostratum* Dun. BUFFALO BUR, KANSAS-THISTLE, MALA MUJER. Annual to about 7 dm. high, somewhat hoary or yellowish with a copious wholly stellate pubescence, copiously armed with straight prickles; leaves mostly once- or twice-pinnatifid, similar to those of *S. citrullifolium*; racemes with pedicels soon ascending; calyx nearly hidden by spinelike prickles; corolla yellow, about 25 mm. in diameter, hardly irregular, the short lobes broadly ovate; stamens and style much-declined, the lowest anther much larger and longer than the others and with an incurved beak; berry wholly enclosed by the close-fitting and often adherent calyx; seeds coarsely undulate-rugose. An aggressive weedy plant of over-grazed land, flats and waste places, generally, throughout Tex., Apr.-Oct.; from Neb. to Tex. and adv. eastw. and northw.

8. *Solanum citrullifolium* A. Br. MELON-LEAF NIGHTSHADE. Annual, much-branched and spreading, to about 7 dm. high, pubescent with gland-tipped simple hairs mixed with scattered few-rayed stellate hairs, armed with straight prickles; leaves irregularly or interruptedly bipinnatifid, the lobes rounded or obtuse and repand; pedicels spreading; corolla violet, to about 37 mm. in diameter, somewhat irregularly 5-cleft, the lobes ovate and acuminate; anthers linear-lanceolate, with 4 yellow and a larger one tinged with violet; fruit enclosed by the close-fitting and very prickly calyx; seeds thickish, coarsely undulate-rugose. *S. heterodoxum* Dun. Roadsides and waste places in cen. and w. Tex., Apr.-Oct.; from Tex. and N.M., locally n. to Ia. and e. to Atl. States.

9. *Solanum sisymbriifolium* Lam. STICKY NIGHTSHADE. Annual to about 7 dm. high, green, stout, villous-pubescent with simple or more or less glandular and viscid hairs, mixed (especially on the leaves) with some few-rayed stellate hairs whose middle division is elongated, heavily armed throughout with long-subulate straight unequal prickles; leaves deeply pinnatifid, the oblong lobes sinuate or even again somewhat pinnatifid; pedicels spreading at maturity; flowers several or numerous in terminal or soon lateral pedunculate racemes; lobes of the 5-parted calyx lanceolate to ovate-lanceolate; corolla light-blue or white, to 25 mm. in diameter or more, 5-lobed; anthers equal, yellow; berry red, globose, 1.5-2 cm. in diameter, loosely and completely or incompletely enclosed by the spiny calyx; seeds minutely reticulate-pitted. Roadsides, waste places and other such areas mostly in e. Tex., May-Sept.; a nat. of Braz. that is adv. or escaped from cult. from Tex. to Fla., n. to N.E. and O.

10. *Solanum Jamesii* Torr. WILD POTATO. Plant usually short, erect or spreading and bushy, to 5 dm. high, usually less than 3 dm., essentially glabrous (in ours), somewhat bluish-green, stoloniferous and tuber-bearing; tubers small, sometimes as many as 50, 5-20 mm. in diameter, globose to ellipsoid, creamy-white or light-brown in color; stem slender, usually much-branched; leaves odd-pinnate, to 15 cm. long, rarely with several small obsolescent interstitial leaflets; leaflets 7 to 11, linear-oblong to somewhat lanceolate, to 6 cm. long and 2 cm. wide, usually much smaller; inflorescence few-flowered, cymosely paniculate; pedicels 1-2 cm. long, prominently articulate at about or above the middle; calyx 4-8 mm. long, irregularly lobed to about the middle; corolla white, stellate, about 25 mm. in diameter, the lobes ovate-lanceolate to triangular-lanceolate and acutish; fruit globose, about 1 cm. in diameter. Rare in mts. of the Trans-Pecos, July-Sept.; from w. Neb., Colo., s.e. Ut., Ariz., N.M. and w. Tex. to Son. and S.L.P.

11. *Solanum leptosepalum* Correll. WILD POTATO. Plant slender, bushy, lax, 4 dm. or more high, essentially glabrous or sparsely and finely pilose throughout, pale-green, probably tuber-bearing; stem stramineous, provided with fine short incurved hairs; leaves odd-pinnate, very thin-herbaceous, with scattered hairs on margin, granulose-appearing or finely pilose on lower surface, to 2 dm. long; interstitial leaves absent or minute; leaflets 5 or rarely 7, broadly ovate to ovate-elliptic, the lowermost pair much-reduced, to 7 cm. long and 35 mm. wide; inflorescence few-flowered; pedicels about 12 mm. long, articulate at about or well above the middle; calyx 6-8 mm. long, the lobes ovate-lanceolate and long-acuminate; corolla light purplish-lavender to white, rotate-pentagonal, about 25 mm. in diameter; fruit globose, about 15 mm. in diameter. In mts. of the Trans-Pecos, Aug.-Oct.; also n. Mex.

12. *Solanum Fendleri* Gray. WILD POTATO. Plant slender to somewhat bushy, erect or ascending, to 5 dm. high, more or less coarsely pilose throughout, stoloniferous and tuber-bearing; tubers small, globose to ellipsoid, white to purplish, to 3 cm. long; stem simple to much-branched; leaves odd-pinnate, to 25 mm. long, with or without small interstitial leaflets; leaflets 5 to 9, ovate to oblong-elliptic or rarely obovate, obtuse to acute at apex, to 8 cm. long and 35 mm. wide; inflorescence several-flowered, racemose

or paniculate; pedicels to 3 cm. long, articulate well above the middle or sometimes just below the calyx; calyx 4-7 mm. long, with ovate-lanceolate lobes; corolla blue or purplish to rarely white, rotate-stellate, rarely more than 3 cm. in diameter, the lobes broadly triangular-ovate; fruit globose, about 1 cm. in diameter. Rare in mts. of the Trans-Pecos, July-Sept.; from Colo., s. through Ariz., N.M., w. Tex. and n. Mex. to Zac.

The var. *texense* Correll is a taller and more open plant than var. *Fendleri*. The inflorescence, especially the calyx, is grayish in color which is caused, in part, by the dense grayish pubescence. The white to white-lavender corolla is more deeply lobed, with narrower and more acute acumens, and the calyx is irregularly and more deeply lobed than usual.

13. *Solanum triflorum* Nutt. CUTLEAF NIGHTSHADE. Annual, with more or less pubescent stem commonly branching and again branching from near base, to about 4 dm. high or long; leaves with a petiole to 15 mm. long, oblong, deeply pinnatifid, with rounded sinuses, to about 4 cm. long and 2 cm. wide, the lobes linear; peduncles 1- to 3-flowered, the pedicels soon reflexed; corolla white, scarcely 1 cm. broad; berry globose, green, 1-1.5 cm. in diameter. Dry plains and open woods, often as a weed of fields and roadsides in the Trans-Pecos, Apr.-Sept.; from B.C. to Calif., e. across the plains to Minn., Ia., Kan. and Okla., and as an adv. weed occasionally e. to the Atl. States.

14. *Solanum aculeatissimum* Jacq. COCKROACH BERRY, SODA APPLE NIGHTSHADE, BERENJENA. Perennial, slightly woody, usually much-branched, to about 12 dm. high, villous with scattered long and weak jointed hairs or soon nearly glabrate, beset throughout with slender-subulate straight prickles; leaves rather large, thin, ovate in outline, pinnately lobed or repand, often slightly cordate at base, to about 15 cm. long and wide; peduncle lateral, short, few-flowered; calyx about one third as long as the corolla, with stout prickles, its lobes ovate-lanceolate lobes acute; corolla white, rotate, 12-25 mm. in diameter, its lobes ovate-lanceolate; anthers ovate-lanceolate; berry globose, scarlet, glabrous, 2-5 cm. in diameter; seeds very flat and thin, with a membranaceous border. In open woodlands along rivers and in waste grounds in s.e. Tex., Apr.-Oct.; in s. U.S., Berm., W.I. and cont. trop. Am.

15. *Solanum pseudocapsicum* L. JERUSALEM-CHERRY. Small branching leafy shrub to about 12 dm. high, erect and glabrous throughout; leaves narrowly lanceolate to oblong or oblanceolate, to 1 dm. long, entire or the margins slightly repand, narrowed at the base to a short petiole, mostly obtuse at apex, the surface bright-green and shining, the veins prominent; flowers solitary or few in lateral clusters, small; calyx lobes lanceolate, eciliate, about 2.5 mm. long; corolla white, 11-14 mm. in diameter, the eciliate lobes ovate-oval to oval; anthers elliptic; berry globose, scarlet to orange or yellow, 1-2 cm. in diameter. Along roadsides, cult. ground and waste places, thickets and woodlands in s.e. Tex., May-Sept.; nat. of the Old World that has become naturalized throughout trop. and subtrop. regions in the World.

16. *Solanum triquetrum* Cav. TEXAS NIGHTSHADE, HIERBA MORA. Perennial, nearly glabrous, varying from a short shrub to a somewhat elongated scandent shrub to 2 m. high; stems suffruticose, flexuous or sarmentose, the branches angled but hardly triquetous; leaves deltoid-cordate, to 5 cm. long or more, varying to hastate or even hastately 3- or 5-lobed, with the middle lobe lanceolate to linear and prolonged; cymes commonly umbellately few-flowered, the peduncles slender; pedicels nodose-articulated at base, in fruit clavate-thickened at the summit; corolla stellate, white or tinged violet, to about 15 mm. in diameter; berry globose, red, 1-1.5 cm. in diameter. S. *Lindheimerianum* Scheele. On low hills, slopes and in thickets and on breaks in cen., s. and w. Tex., flowering throughout the year; also adj. Mex.

This is a highly variable species, especially in regard to its habit and leaf shape.

17. *Solanum villosum* Mill. HAIRY NIGHTSHADE. Low somewhat viscid-pubescent or villous plants, resembling small-leaved forms of *S. americanum* but cinereous with dense appressed villosity or pilosity; leaves small, conspicuously angulate-dentate; the 1 to 5 umbellate small flowers on slenderly clavate stiff pedicels; calyx as in *S. americanum* but densely pubescent; corolla white, the lobes 4-5 mm. long; berries yellow or red; seeds usually 1.8-2.2 mm. long. On rocky slopes and waste places in the Trans-Pecos, July-Oct.; from Mass. southw.

Plants here previously referred to the *S. nigrum* L. complex.

18. *Solanum Douglasii* Dun. Perennial, often suffrutescent, sometimes to 3 m. high, usually much smaller, sparsely to densely cinereous-puberulent or short-pilose, the hairs mostly appressed or subappressed; leaves entire to variously angulate-toothed; flowers commonly in umbelliform cymes or sometimes solitary, these borne on peduncles nearly as long as or longer than the pedicels; corolla white or purple-tinged, 1-1.8 cm. in diameter; fruiting calyx erect; berries black at maturity, many seeded, persistent. In igneous soil or on sandy banks in mts. of the Trans-Pecos, June-Oct.; w. to Calif. and adj. Mex.

Plants here previously referred to the *S. nigrum* complex.

19. *Solanum nodiflorum* Jacq. Plant slender, annual or perennial, often tall, sparsely puberulent to strigose or glabrate; leaves firm, entire to sparsely sinuate-dentate, acuminate; flowers commonly in umbelliform cymes or sometimes solitary, these borne on peduncles nearly as long as to longer than pedicels; calyx firm, the lobes all distinct and reflexed in fruit; corolla white or sometimes tinged with purple, not more than 8 mm. wide; berries black at maturity, concretions of stone cells absent or few (rarely more than 3). Reported from coastal Tex. but no material matching this has been seen; probably referable to *S. americanum*.

Plants here previously referred to the *S. nigrum* complex.

20. *Solanum americanum* Mill. AMERICAN NIGHTSHADE, HIERBA MORA NEGRA. Slender usually divergently branched glabrous or glabrescent annual, to 1 m. high; leaves slender-petioled, ovate to oval or ovate-lanceolate, entire to sinuate-dentate, pale-green, membranaceous, to 1 dm. long, translucent to transmitted light; peduncles filiform, to 3 cm. long; umbels 2- to 4-flowered, with filiform soon reflexed pedicels; calyx of unequal acutish to blunt spreading lobes 1-1.5 mm. long; corolla white or purple-tinged, its lobes 4.5-7 mm. long; anthers 1.3-2 mm. long; berry lustrous-black, 5-9 mm. in diameter, with 4 to 8 stone cell concretions in most berries, quickly falling when ripe; seeds 1.2-1.8 mm. long. In rocky or dry open woods, thickets, shores or openings, often spreading to cult. or waste ground, throughout Tex., blooming throughout year; from N.E. to N.D., s. to Fla., La. and Tex.

Plants here previously referred to the *S. nigrum* complex.

5. CAPSICUM L. CAYENNE PEPPER

About 50 species, all of which are indigenous to tropical or subtropical America.

1. *Capsicum annum* L. var. *minus* (Fing.) Shinners. BIRD PEPPER, CHILE PIQUÍN, CHIL-LIPIQUIN. An intricate shrub with slender divergent brittle green branches, to 3 m. high (or long), glabrous or very sparsely puberulent; leaves ovate to elliptic-lanceolate or lanceolate, acute to acuminate, to 6 cm. long and 3 cm. wide, exceeding the slender petioles; pedicels long and slender, often in pairs, spreading or somewhat reflexed, somewhat stoutish in fruit; calyx small, shallowly toothed in flower but truncate and cup-shaped in fruit; corolla stellate, whitish, about 7 mm. wide; anthers generally bluish; fruit ovoid to nearly globose, persistent, red or yellowish, to about 15 mm. long, pungently aromatic. *C. baccatum* and *C. frutescens* of Tex. auth. On ledges along rivers, in thickets and groves and along arroyos on the Edwards Plateau and in s. Tex., flowering throughout the year; from Tex. to Ariz.; also s. Fla. and throughout trop. Am.

The extremely pungent berries are used as a condiment and medicinally as a local stimulant.

6. MARGARANTHUS SCHLECHT.

A monotypic genus.

1. *Margaranthus solanaceus* Schlecht. NETTED GLOBE-BERRY. Nearly glabrous erect slender annual closely resembling *Physalis*, to about 6 dm. high, more or less sparingly divergently-branched from the base; leaves petioled, membranaceous, ovate to lanceolate, entire to somewhat sinuate, occasionally 1- or 2-toothed, 2.5-5 cm. long; pedicels short, recurving; corolla greenish, yellow or lurid-purple, cylindrical-urceolate, merely dentate at the orifice, barely 4 mm. long; berry small, entirely included in the globular-conical

fruiting calyx that is 8-12 mm. long; seeds 20 to 30. In fields and pastures in s. and w. Tex., July-Nov.; from Tex. to Ariz. and n. Mex.

7. LYCIUM L.¹⁷³WOLFBERRY. DESERT-THORN. SQUAW-BERRY
TOMATILLO. CILINDRILLO

Plants shrubby, usually spiny; leaves mostly fascicled, entire; flowers chiefly axillary, solitary or in small clusters; calyx campanulate, irregularly toothed or cleft into 4 to 6 lobes; corolla campanulate, tubular-funnelform or salverform, the limb 4- to 7-lobed; stamens 4 or 5; style slender, the stigma capitate or 2-lobed; berry fleshy or dry, globose or ovoid, subtended by the persistent calyx.

About 85 species, mostly in warmer regions in America. Some species produce abundant quantities in insipid, slightly bitter, juicy berries that are eaten raw or prepared as a sauce. The species also provide winter forage for livestock.

1. Calyx lobes from two thirds as long to as long as or longer than tubular portion, or if not two thirds as long as tube then at least 2 mm. long; calyx cleft equally, never noticeably 2-lipped, therefore the lobes about equal in length (2)
1. Calyx lobes less than two thirds as long as tube, usually less than 2 mm. long; calyx frequently irregularly cleft or more or less 2-lipped (5)
- 2(1). Corolla lobes more than one third as long as tube . . . 1. *L. carolinianum* var. *quadrifidum*.
2. Corolla lobes not over one third as long as tubular portion, usually much less (3)
- 3(2). Leaves densely glandular-puberulous, not glaucous . 2. *L. puberulum*.
3. Leaves glabrous, smooth, glaucous (4)
- 4(3). Pedicels about 10 mm. long; corolla 2 cm. long, the tube 4 mm. or more in diameter at summit; leaves glaucous-green 3. *L. pallidum*.
4. Pedicels to 4 mm. long; corolla 1 cm. long, the tube less than 4 mm. in diameter at summit; leaves glaucous-gray 4. *L. berberioides*.
- 5(1). Leaves densely hispidulous-puberulous; pedicels (at anthesis) about 1.5 mm. long 5. *L. texanum*.
5. Leaves essentially glabrous; pedicels (at anthesis) 3-6 mm. long (6)
- 6(5). Corolla lobes shortly but densely white-lanate-ciliate, pubescence usually visible to the unaided eye as a white fringe 6. *L. Torreyi*.
6. Corolla lobes smooth, not densely lanate-ciliate (7)
- 7(6). Flowers 6-8 mm. long 7. *L. Berlandieri* f. *Berlandieri*.
7. Flowers 4-6 mm. long 7. *L. Berlandieri* f. *parviflorum*.

1. *Lycium carolinianum* Walt. var. *quadrifidum* (Dun.) C. L. Hitchc. CAROLINA WOLFBERRY. A rather sparingly branched armed shrub, erect or slightly spreading, to 1 m. tall, glabrous; young branchlets often with short thick spines about 1 cm. long or branchlets unarmed; older branchlets with spinose branchlets, tan to dark-gray; leaves 3 to 10 in a fascicle, narrowly terete-spatulate to spatuloid, somewhat succulent, 1-2.5 cm. long, 1-2 mm. broad, the midnerve scarcely visible, rounded or occasionally somewhat acute at apex, attenuate at base, practically sessile, glabrous; pedicels to 3 cm. long; calyx cup-shaped, glabrous, about 3 mm. long; calyx lobes 4, triangular, obtuse, nearly equaling the tube, margins sometimes remotely ciliate; corolla lavender to purple, rotate-campanulate, 7-10 mm. long; corolla tube about equal to lobes or slightly shorter, 1-1.5 mm. in diameter at top of ovary, 3-5 mm. in diameter at summit, glabrous without; corolla lobes 4, rarely 5, ovate, abruptly contracted at base, rounded or slightly emarginate at apex, spreading, their margins not ciliate or but very sparsely so; stamens exerted due to spreading of lobes of the corolla; filaments adnate to about midway from the base of the tube,

¹⁷³ Adapted partly from C. L. Hitchcock in Ann. Missouri Bot. Gard. 19:179-374. 1932.

equaling or somewhat shorter than corolla lobes, densely pilose on their lower one-third or one-fourth of free portion, the adjacent corolla tube only very sparsely hairy; anthers 1-1.5 mm. long; style scarcely as long as filaments; berry ovoid, fleshy, red, about 1 cm. in diameter, with 50 or more seeds, purple in old or dried material. About ponds, along and in ditches, marshes, on wet clay flats, salt flats, and in sandy-gravelly soil on brush-covered hills in coastal and s. Tex., Jan.-Nov.; from Miss. to Tex. and n.e. Mex.

2. *Lycium puberulum* Gray. **DOWNY WOLFBERRY.** A sparingly branched spiny shrub to 15 dm. tall; branches usually slender and flexuous, well-armed with slender needlelike spines 5-10 mm. long, dark-grayish-green to olive-purple, glabrous at least in age; leaves 3 to 6 in a fascicle, broadly elliptic to oblong-obovate, 5-15 mm. long, about one third as broad as long, rounded at apex, sessile or subsessile, densely glandular-puberulent, not fleshy, midnerve evident; flowers 1 or 2 in the leaf fascicles, the pedicels about 2 mm. long; calyx broadly campanulate, 4-6 mm. long, very densely glandular-puberulent, the 5 lobes oblong-ovate and equal to or twice the length of the calyx tube, glandular-puberulent on both surfaces; corolla tubular-campanulate; corolla tube white, 9-12 mm. long, 1.5 mm. wide at base, about 3 mm. in diameter at top, glabrous without; corolla lobes 5, ovate, one fifth to one fourth the length of the tube, commonly spreading, their margins not ciliate; stamens equal to corolla tube or slightly shorter; filaments equal or subequal, adnate to the corolla tube for about two thirds of its length, glabrate but the lower two thirds of the corolla tube densely hairy; anthers 1 mm. or less long; style equaling or slightly shorter than filaments, included in corolla tube; fruit sclerenchymatous, 1 or 2 seeds in each cell. In limestone desert hills and shrubby grasslands in the Trans-Pecos, Mar.-Aug.; apparently endemic.

3. *Lycium pallidum* Miers. **PALE WOLFBERRY.** Densely branched spreading spiny shrub 1-2 m. tall; branches often somewhat flexuous, yellow to gray or more commonly reddish to purple, glabrous or rather sparsely pubescent, the slender spines sharp and 5-10 mm. long, the longer spines usually somewhat blunt; leaves glaucous-green, glabrous or glabrate, oblong-spatulate to broadly elliptic or nearly ovate, acute or occasionally rounded at apex, 1-4 cm. long, 3-15 mm. broad, attenuate at base into a short petiole, midnerve and primary lateral nerves usually visible; flowers borne singly or in pairs, the pedicels equaling or slightly exceeding the calyx; calyx cup-shaped to campanulate, blue-glaucous and glabrous, 5-8 mm. long, two thirds as broad at summit, 5-lobed; calyx lobes lanceolate to ovate or elliptic, equaling or even exceeding the tube, their margins sometimes sparsely pubescent; corolla tube elongate-funnelform, 1.2-2 cm. long, about 1.5 mm. in diameter above the ovary, 5-6 mm. in diameter at top where it is expanded conspicuously, greenish with purple veins, often blue-glaucous on outside; corolla lobes 5, oval or rhombic, one fifth to one third the length of the tube, their margins commonly very remotely ciliolate; stamens usually slightly exerted, sometimes extending only to the base of the corolla lobes; filaments adnate to a little below the middle of the corolla tube, free base of the filaments and the adjacent corolla tube hairy; anthers 1.5 mm. long; style varying in length from about equal to corolla tube to 4 or 5 mm. longer than tube; berry red or reddish-blue due to glaucescence, ovoid, about 1 cm. or slightly less in diameter, 20- to 50-seeded. In limestone soils on steep rocky slopes and among grasses in canyons in the Trans-Pecos, Feb.-May; from s. Colo. and Tex. to s. Ut., Ariz. and n. Mex.

4. *Lycium berberoides* Correll. **SILVERY WOLFBERRY.** Intricate shrub to about 15 dm. tall, profusely branched and spiny, the entire plant (when observed in nature) silvery- or dusty-gray; leaves gray-glaucous, elliptic to elliptic-obovate, obtuse to rounded at apex, veiny and somewhat marginate, to 1 cm. long and 3.5 mm. wide; flowers borne 1 or 2 at the nodes; pedicels stout, 1-4 mm. long at anthesis; calyx herbaceous, 4-5 mm. long, the usually reflexed ovate obtuse lobes as long as the tubular portion; corolla greenish-white, green-lined within the tube, about 1 cm. long, the triangular-ovate subacute lobes about 3 mm. long and usually reflexed; stamens and style included. On rocky hills or on stony flats in creosote shrub association in the s. Trans-Pecos, Mar.-Apr.; endemic.

5. *Lycium texanum* Correll. **TEXAS WOLFBERRY.** Intricate thorny shrub, the young branchlets brownish and hispidulous; leaves linear-oblancoate to narrowly spatulate, hispidulous-puberulous, often mucronulate at the obtusely rounded apex, to 2 cm. long and 3 mm. wide, usually much smaller; flowers borne 2 to a node; pedicels (at anthesis) about 1.5 mm. long, becoming much longer in fruit, hispidulous; calyx minute, scarious,

hispidulous, 2-3 mm. long, minutely lobed and somewhat 2-lipped; corolla 7-8 mm. long, the small slightly ciliate lobes strongly revolute; stamens and style somewhat exserted. In sandy soil and rocky areas in canyons of the Trans-Pecos, July-Oct.; endemic.

6. *Lycium Torreyi* Gray. Much-branched spreading shrub to 3 m. tall, with heavy spines 5-10 mm. long or practically unarmed; branches densely leafy, glabrate; leaves usually spatulate but sometimes elliptic or oblanceolate, to 5 cm. long and 15 mm. broad, usually somewhat acute at apex, attenuate at base to a short petiole 2-3 mm. long, the midnerve visible; flowers 1 to 3 in a fascicle; pedicels 5-20 mm. long; calyx cup-shaped to tubular, 2.5-4.5 mm. long, about 2 mm. in diameter, sparsely pubescent to glabrate; calyx lobes 5, one fourth to one half the length of the tube, triangular, the margins somewhat ciliate; corolla tube narrowly obconic, 8-15 mm. long, somewhat constricted at top of ovary, flared slightly at summit, 1.5-2 mm. in diameter at base, 3-4 mm. in diameter at top, greenish-lavender or whitish, usually glabrous without but sometimes with few scattered hairs; corolla lobes 5 (less commonly 4), rounded to oval or even lanceolate, 1 to 3 times as long as broad, and one fifth to one fourth the length of the tube, spreading, their margins densely ciliate-lanate with branched hairs which are apparent as a tiny white fringe; stamens equaling or slightly shorter than the corolla lobes; filaments adnate to about the middle of the corolla tube, rather densely hairy for about the first 1.5 mm. of their free portion, the adjacent corolla tube also hairy; anthers 1-1.5 mm. long; style slightly longer than the stamens, usually exserted 2-3 mm. beyond corolla tube; berry ovoid, 6-10 mm. long, two thirds as thick, bright-red, 8- to 30-seeded; fruit very juicy, sweet and not unpalatable. In silty soils, along canals and on flats in the Trans-Pecos, Apr.-Oct.; from Tex. to s.e. Nev. and Calif., s. to Hgo.

7. *Lycium Berlandieri* Dun. var. *Berlandieri*. A rather sparingly branched glabrous or pubescent shrub to 25 dm. tall, armed with few needlelike spines at ends of young branches or practically unarmed; branches somewhat crooked, decumbent, sparingly leafy, slender, silvery-gray to reddish; leaves glabrate, sometimes finely pubescent, linear to elliptic-spatulate, to 25 mm. long and 2.5 mm. broad, rounded or sometimes acute at apex, 1 to 3 in a fascicle; flowers borne singly or in pairs, the pedicels 3-20 mm. long; calyx cup-shaped, 1-2 mm. long and nearly as wide, the 3 to 5 lobes equal and about one third as long as tube or unequal, the calyx frequently splitting nearly to base on one side, glabrous except for a small tuft of hair at the tip of each lobe, infrequently the whole calyx pubescent; corolla blue or pale-lavender; tubular portion of corolla obconic-infundibuliform, much-constricted immediately above calyx, 4-8 mm. long, 2-4 mm. in diameter at the summit, 1 mm. in diameter or less just above the calyx, glabrate without, sometimes with few scattered hairs just above and below the summit of calyx; corolla lobes 4 or 5, one sixth to one third the length of the tube, usually reflexed and sometimes recurved; stamens unequal or subequal, about equal to corolla lobes; filaments adnate to a point about one third way from base of tube, hairy for the first one fourth to one third of their free portion, the adjacent corolla tube only slightly hairy; anthers about 1 mm. long; style equaling or very slightly exceeding stamens; berry globose-ellipsoid, red, about 4 mm. in diameter, 8- to 30-seeded. On gravelly-rocky hills, limestone and clay flats, alkali flats, gypsum soil in arroyos, scrubland and thickets from coastal and s. Tex. to the Trans-Pecos, Feb.-Oct.; from Tex. to e. N.M. and n. Mex.

Plants with stouter and more leafy branches, nodes frequently cottony and smaller flowers (4-8 mm. long) than in typical material are designated as var. *parviflorum* (Gray) Terrac. (var. *brevilobum* C. L. Hitchc.). It occurs in similar habitats to those of var. *Berlandieri* but seems to be confined to w. Tex. and n. Mex.

 Matrimony-vine (*L. halimifolium* Mill.), an old-fashioned garden plant, occasionally spreads from cultivation into thickets and waste ground. Long, sarmentose, recurved-drooping, essentially unarmed branches and greenish-purple flowers are characteristics of the plant.

8. CESTRUM L.

Deciduous or evergreen shrubs or small trees; leaves alternate, simple and entire; flowers in axillary or terminal cymes; calyx 5-toothed, short; corolla salverform or funnel-

form, variously colored, with long slender tube, enlarged or contracted at mouth, with short limb; stamens inserted about the middle of the corolla tube, included; filaments filiform, often pilose below, sometimes with a toothlike appendage; anthers small, their sacs parallel; ovary 2-celled, usually short-stipitate; ovules few; style filiform, the dilated stigma entire or 2-lobed; fruit a small berry; seeds oblong, smooth.

About 150 species in tropical and subtropical America. Several species cultivated for their fragrant flowers.

1. Lobes of corolla becoming distinctly reflexed; berry black 1. *C. diurnum*.
1. Lobes of corolla erect or spreading; berry not black (2)
- 2(1). Leaves ovate-oblong to elliptic, short-acuminate; berry white 2. *C. nocturnum*.
2. Leaves lanceolate, very long-tapering; berry violet-brown 3. *C. Parqui*.

1. *Cestrum diurnum* L. DAY JESSAMINE. A shrub to about 2 m. high, the slender twigs and inflorescence glabrous or more or less pubescent; leaves with slender petioles to 12 mm. long, oblong to oblong-elliptic, membranous, light-green, to 11 cm. long and 25 mm. wide, obtuse to acute at apex, narrowed to obtuse at base; panicles several-flowered, about as long as the leaves or shorter, often with some leaflike bracts; flowers fragrant; calyx campanulate, 3-3.5 mm. long; corolla white, 1-1.8 cm. long, its oblong lobes obtuse and reflexed at anthesis; stamens straight, edentate; berry black, ellipsoid, 6-7 mm. long.

A West Indian species that occasionally escapes from cultivation.

2. *Cestrum nocturnum* L. NIGHT JESSAMINE. Shrub to about 3 m. high, with glabrous angled slender branchlets; leaves thin, with a distinct petiole to 2 cm. long, mostly ovate-oblong to elliptic, short-acuminate, to 15 cm. long, mostly about 35 mm. wide, glabrous and more or less shining on both sides; panicles large, several- to many-flowered, longer than the leaves; pedicels short or the lower ones 5-9 mm. long; flowers yellow or greenish-yellow, pungently fragrant (especially at night); calyx tubular-campanulate, about 3 mm. long, its teeth short; corolla narrowly funnelform, 18-25 mm. long, the limb about one fourth as long as the tube, the acute lobes erect or only spreading; filaments toothed near the base; berry ellipsoid, white, about 1 cm. long. Nat. to W.I., occasionally escapes from cult. in s. Tex.

3. *Cestrum Parqui* L'Hér. WILLOW-LEAVED JESSAMINE. Upright shrub to 2 m. high, glabrous; leaves with petioles 5-10 mm. long, lanceolate, 5-14 cm. long, usually not much exceeding 25 mm. wide, cuneate at base, acuminate at apex, bright-green, slightly paler beneath; flowers in axillary and terminal cymes that form panicles at end of branches; corolla yellowish-green, pungently fragrant at night, the slender tube 2-2.5 cm. long and dilated at mouth, with spreading acute lobes; fruit violet-brown, 3- or 4-seeded. A Chilean species, allied to *C. nocturnum*, that is cult. for its fragrant flowers, occasionally escapes.

9. SCHIZANTHUS R. & P.

BUTTERFLY-FLOWER

A small South American genus of 15 or more species, several of which are cultivated.

1. *Schizanthus pinnatus* R. & P. Annual or biennial, thinly hairy and somewhat glandular, to 12 dm. high, usually much smaller, slender-branching; leaves linear-oblong in outline, to 1 dm. long or more, 1- or 2-pinnatisect, the segments entire to toothed or incisedly pinnatifid; inflorescence elongate, of numerous flowers in paniced racemes; calyx 6-7 mm. long, cleft to base to form linear to oblanceolate obtuse lobes; corolla tubular, 2-3 cm. across, varying in depth of color and markings, the lower lip usually violet or lilac, the upper lip paler, its middle segment with a yellow blotch toward the base, spotted with purple or violet; corolla tube shorter than the calyx; stamens prominently showing at the throat; ovary oblong, 2-celled; capsule with 2-cleft valves; seeds numerous. A Chilean species that occasionally escapes from cult. or occurs in waste places in s. Tex.; Apr.-Aug.

10. SALPICHROA MIERS

About 25 species of southwestern United States and extra-tropical South America.

1. *Salpichroa origanifolia* (Lam.) Baill. COCKS-EGGS. Weedy perennial climber from a fleshy root, somewhat woody, with green flexuous branches and a strong odor, puberulent to nearly glabrate; leaves subopposite, ovate-rhombic to suborbicular, 1.5-4 cm. long and wide, narrowed to a slender petiole that is shorter than the blade; flowers nodding, on filiform pedicels scarcely shorter than the petioles; calyx lobed to near the base, about 2.5 mm. long; corolla short, white, urceolate, constricted below the middle and at the throat, 7-10 mm. long, the 5 short lobes revolute, the inside of the tube with a woolly ring; stamens inserted at about the middle of the corolla tube or even higher; style slender, commonly exserted; berry ovoid-oblong, yellow or white, many-seeded, said to be edible but of poor flavor. *S. rhomboidea* (Gill. & Hook.) Miers, *Pertzoma rhomboidea* ("Hooker") Small. A nat. of S.A. that occasionally escapes from cult. in s.e. Tex., Mar.-July.

11. NIEREMBERGIA R. & P. CUP-FLOWER

About 30 species, mainly in tropical and subtropical America.

1. *Nierembergia hippomanica* Miers var. *coerulea* (Miers) Millan. Plant to about 2 dm. high, somewhat scabrous-pubescent, with suberect branches; leaves alternate, solitary and fascicled, linear to linear-spatulate, to 16 mm. long, usually much smaller, less than 2 mm. wide; flowers borne singly at or near the tips of the branchlets; pedicels at anthesis 3-5 mm. long; calyx tubular, scarious, 6-10 mm. long, with 10 conspicuous green ribs, the 5 narrowly triangular acuminate lobes more than half as long as the tube; corolla similar in appearance to *Leptoglossis texana*, bright-blue, the filiform tube 7-10 mm. long, the broadly 5-lobed saucer-shaped limb about 2 cm. in diameter; stamens subequal, 6-7 mm. long, inserted on the upper part of the corolla tube, more or less exserted, often with 4 of them paired and the fifth smaller; style exserted about 6 mm. beyond the corolla tube; capsules bivalved, the valves mostly 2-cleft. A S.A. species that occasionally escapes from cult., especially in s. Tex.

12. PETUNIA Juss.

About 40 species, mostly in South America.

1. *Petunia parviflora* Juss. WILD PETUNIA, SEASIDE PETUNIA. Annual; stems leafy, prostrate and rooting at the nodes, diffusely branched to form mats to 3 dm. wide or more, glandular-puberulent; leaves linear-oblong to spatulate, fleshy, about 1 cm. long; flowers solitary, lateral, on very short peduncles; calyx 5-parted to below middle; sepals in fruit to 11 mm. long and 1.5 mm. wide, linear-oblong to linear-spatulate, obtuse; corolla funnelform, purple or reddish-violet, with yellow or whitish tube and 5 minute unequal retuse lobules that are plicate in bud, the tube about 6 mm. long; stamens inserted low in corolla; filaments 3 short and 2 longer; capsules 3-4 mm. long, ovoid-ellipsoid, acute, 1-celled, bivalved, the valves leathery-chartaceous; seeds numerous, angular and more or less raised-reticulate. In moist or wet soil in beds of streams, along beaches and on muddy flats in most of Tex., Apr.-Sept.; from s. Fla. to Calif., n. to Va., s. to trop. Am.

Our plant is a "poor" relative of the showy cultivated petunias that are derived from *P. axillaris* (Lam.) B.S.P. and *P. violacea* Lindl. of South America.

13. DATURA L.¹⁷⁴ STRAMONIUM. JIMSON-WEED. THORN-APPLE

Rank weeds, narcotic-poisonous, herbaceous (in ours), some tropical species woody and arborescent; leaves ovate to elliptic in outline; flowers usually large and showy, mostly

¹⁷⁴ Ref.: W. E. Safford in Jour. Wash. Acad. 11:173-189. 1921.

fragrant, produced all summer and autumn on short peduncles in the forks of the branching stem; calyx prismatic or cylindrical, 5-toothed, separating transversely above the base in fruit, the upper part falling away; corolla funnelform to tubular, with a usually large and spreading 5- or 10-toothed plaited limb; stigma 2-lipped; capsule globular, usually prickly, 4-valved, 4-celled except near the 2-celled top; seeds rather large, flat.

About a dozen species mainly in warm and tropical regions of the World.

1. Fruit nodding, usually bursting irregularly at maturity, globose or nearly so; leaves entire to repand or sinuate-dentate; corolla more than 10 cm. long (2)
1. Fruit erect, regularly dehiscent, ovoid, 4-valved; corolla not more than 10 cm. long (3)
- 2(1). Plants (especially new growth) densely villous or glandular-villous with spreading hairs; lower surface of leaves soon glabrate except for the primary veins 1. *D. inoxia*.
2. Plants merely cinereous-puberulent with short appressed or curved hairs; lower surface of leaves velvety to the touch 2. *D. Wrightii*.
- 3(1). Spines of the fruit numerous, subequal, less than 1 cm. long, relatively slender, sometimes much-reduced or wanting; leaves repand to coarsely sinuate-dentate; corolla 7 cm. long or more, whitish or purplish 3. *D. Stramonium*.
3. Spines of the fruit relatively few, very unequal, the longer ones more than 1 cm. long, very stout; leaves usually pinnately lobed; corolla not more than 7 cm. long, purplish 4. *D. quercifolia*.

1. *Datura inoxia* Mill. INDIAN-APPLE. Plant annual from a perennial rootstock, widely branching, to 1 m. high or more, the herbage (especially new growth) densely villous and sometimes also glandular with spreading hairs; leaves ovate, to 25 cm. long, asymmetric at base, acute to acuminate at apex, entire or coarsely sinuate-dentate, the lower surface soon glabrate except for the primary veins, the petiole shorter than to nearly equaling the blade; calyx 8-12 cm. long, unequally 5-toothed, the basal persistent part reflexed in fruit; corolla white, funnelform, 12-15 cm. long, with a spreading limb to 12 cm. across, the limb with 5 (rarely 10) subulate teeth about 1 cm. long; capsule globose, nodding, 3-4 cm. long, densely spiny and glandular-puberulent or short-villous with spreading hairs, when mature rupturing irregularly, the spines mostly less than 1 cm. long; seeds light-brown, 5-6 mm. wide, reniform, plump but compressed. In various types of soils, rocky stream beds, canyons, base of bluffs and on ledges in the Edwards Plateau, Rio Grande Plains and Trans-Pecos, Mar.-Nov.; Tex. and N.M., s. to cen. Mex.

2. *Datura Wrightii* Regel. Plant erect, widely branching, annual from a perennial rootstock, to 15 dm. high, the herbage cinereous-puberulent and somewhat glaucescent-velutinous (especially new growth); leaves ovate, entire to slightly sinuate-repand, to 15 cm. long, asymmetric at base, obtuse to shortly acuminate at apex, the puberulent lower surface soft to touch, the petiole shorter than to nearly equaling the blade; calyx 7-12 cm. long, unequally 5-toothed, the basal persistent part reflexed in fruit; corolla white, commonly suffused with violet or lavender, infundibuliform, to about 15 cm. long, with a spreading limb to about 15 cm. wide, the limb with 5 slender teeth 1-1.5 cm. long; anthers white, about 15 mm. long; capsule globose, nodding, 3-4 cm. in diameter, densely prickly and puberulent with retrorse hairs, the spines less than 1 cm. long; seeds sub-orbicular-reniform, flattened, light-brown, 5-6 mm. wide, smooth on the sides, the margin cordlike. *D. meteloides* of Tex. auth. In loose sand and on floodplains and bottomlands from e. Tex. to the Trans-Pecos, May-Nov.; from Tex., w. to Calif. and n. Mex.

3. *Datura Stramonium* L. JIMSON-WEED, TOLOACHE. Simple to spreading branched erect annual, to 15 dm. high, with green sparsely puberulent to glabrate stems and foliage; leaves ovate to elliptic, to 2 dm. long, sinuately to lanciniately lobed, the petioles about one half as long as the blade; calyx 35-45 mm. long, the unequal teeth 5-10 mm. long, the persistent basal part reflexed in fruit; corolla white, commonly tinged with lavender [var. *Tatula* (L.) Torr.], 6-8 cm. long, the limb 3-5 cm. across and bearing 5 subulate teeth that are 5-8 mm. long; capsule erect, ovoid, 3.5-5 cm. long, usually armed with spines mostly less than 5 mm. long, finely and sparsely puberulent to glabrate, dehiscent from apex by 4 valves; seeds black, rugulose and finely pitted. In cult. areas and waste places throughout Tex., Apr.-Nov.; a weedy species widely distributed in the World.

4. *Datura quercifolia* H.B.K. OAK-LEAF THORN-APPLE. Plant green, annual, to 15 dm. high, the younger parts commonly somewhat downy or pubescent; leaves sparingly but mostly deeply sinuate-pinnatifid; flowers erect; calyx prismatic, 5-toothed, about one half as long as the corolla; corolla tubular, pale-violet to purple, 4-7 cm. long, the limb to about 2 cm. across and with 5 minute teeth; anthers purple; capsule ovoid, 3-4 cm. long, strictly erect, dry, 4-valved, armed with large and very unequal flattened prickles, some of the upper spines as much as 25 mm. long; seeds dark-colored, somewhat scrobiculate-rugose. In sandy or sandy-clayey soils in the Panhandle and Trans-Pecos, May-Oct.; from w. Okla. and Tex. through s. N.M. to adj. Mex.

14. LEPTOGLOSSIS BENTH.

Several species in southwestern United States and northern Mexico.

1. *Leptoglossis texana* (Torr.) Gray. TEXAS CUP-FLOWER. Low perennial, diffusely much-branched from a suffrutescent base, to about 25 cm. high, viscid-pubescent; leaves spatulate-obovate to elliptic-oblongate, obtuse to acute at apex, narrowed at base, to 3 cm. long and 1 cm. wide, the lowermost leaves with a short margined petiole; pedicels mostly shorter than the herbaceous campanulate-funnelform 5-toothed calyx; corolla salverform, light-purple or purple-pink, the filiform tube 16-18 mm. long, the almost regular broadly 5-lobed plane limb to 23 mm. in diameter, the very short campanulate throat scarcely over 2 mm. in height and width; stamens 4, didynamous, the fifth a sterile filament, included in the throat of the long-tubed corolla; winged appendages under the stigma narrower than wide; capsule membranous, 2-valved, only half the length of the 10-nerved calyx; seeds somewhat reniform, coarsely transverse, rugose. *Nierembergia viscosa* Torr., *Browallia texana* Torr. In limestone soil on hills on w. edge of Edwards Plateau, Feb.-May; probably in adj. Mex.

15. BOUCHETIA DC.

A monotypic genus.

1. *Bouchetia erecta* DC. Much-branched from a perennial root, ascending, about 23 cm. high, minutely appressed-puberulent; leaves oblong-spatulate or the lower oval and petioled and the upper lanceolate and sessile, to 5 cm. long and 1 cm. wide, usually much smaller; peduncles terminal or lateral and scattered; calyx oblong-campanulate, 5-cleft with narrow lobes; corolla white, sometimes tinged with lavender, 12-18 mm. long, about twice the length of the calyx, the broadly funnelform limb deeply 5-lobed, the lobes roundish; stamens 5, perfect; anthers connivent, the yellow cells somewhat confluent at summit; stigmas transversely dilated, greenish, somewhat reniform; pod ellipsoid, at length 4-valved, about 8 mm. long; seeds numerous, brown, pitted. *B. anomala* of auth. In clayey or sandy soils and on shell mounds along the coast and in prairies and on rocky slopes in cen. and s. Tex., Mar.-Oct.; apparently endemic.

16. NECTOUXIA H.B.K.

A monotypic genus.

1. *Nectouxia formosa* H.B.K. Annual, erect-ascending, more or less glandular-pubescent throughout, somewhat malodorous; stems simple or branched from base; leaves alternate to subopposite, with slender petioles shorter than the blade, ovate, cordate at base, acuminate at apex, to at least 4 cm. long and 25 mm. wide; peduncle axillary, shorter than the calyx; calyx lobes 5, linear-subulate, about 12 mm. long, densely hirsute; corolla 2.5-3 cm. long, the salverform tube dilated just below the 5-lobed limb, the tubular crown about 4 mm. high; corolla lobes elliptic, obtuse to acute, spreading, about 15 mm. long and 6 mm. wide; stamens attached above the middle of the corolla tube, subincluded, the filaments filiform; anthers oblong, with a dorsal winged connective lengthwise on both sides, with the parallel cells dehiscing lengthwise; disk small; ovary oblong, 2-celled; style filiform, the stigma somewhat expanded; fruit not seen but probably oblong. In Trans-Pecos Tex. and Mex.

17. NICOTIANA L.¹⁷⁵ TOBACCO

Annual or perennial herbs or rarely small trees or shrubs, narcotic-poisonous and heavy-scented, usually viscid-pubescent; leaves entire or sometimes repand or panduriform, petiolate or sessile; flowers few to many in racemes or panicles; calyx tubular-campanulate, 5-cleft; corolla funnelform or salverform, usually with a long tube, the plaited 5-lobed limb usually spreading; stamens 5, variously inserted on the corolla; stigma capitate; capsule ovoid to narrowly ellipsoid, acute or blunt, 2-celled, 2- or 4-valved from the apex; seeds numerous, minute.

About 60 species in North America, South America, Australia and the South Pacific.

1. Trees or large shrubs; leaves glaucous, glabrous; flowers yellow 1. *N. glauca*.
1. Plants herbaceous; leaves green, more or less viscid-pubescent; flowers mostly white, often variously tinged with green, violet or red (2)
- 2(1). Leaves commonly repand or panduriform 2. *N. repanda*.
2. Leaves entire or the margins more or less undulate or crisped (3)
- 3(2). Corolla 12-23 mm. long, greenish; capsule 11 mm. long or less; native to western half of Texas 3. *N. trigonophylla*.
3. Corolla 25 mm. long or more, not noticeably greenish; capsule more than 11 mm. long; introduced in south and east Texas (4)
- 4(3). Stem leaves ample; inflorescence rather compact; filaments elongated, inserted below middle of tubular portion of corolla 4. *N. Tabacum*.
4. Stem leaves much smaller than those of the basal rosette; inflorescence lax and elongated; filaments abbreviated, inserted slightly below mouth of corolla tube (5)
- 5(4). Corolla 4-12 cm. long 5. *N. longiflora*.
5. Corolla 2.5-3.5 cm. long 6. *N. plumbaginifolia*.

1. *Nicotiana glauca* Grah. TREE TOBACCO, MUSTARD TREE, RAPÉ, GIGANTE, BUENA MOZA. Glabrous shrub or small tree to 8 dm. high; leaves long-petiolate, glaucous, somewhat leathery, ovate to oblong-lanceolate, 5-18 cm. long, cuneate to subcordate at the base, obtuse to acute at the apex, entire to slightly repand; flowers in lax terminal panicles; calyx tubular-campanulate, 8-12 mm. long, 5-toothed, the teeth much shorter than the tube; corolla tubular, greenish-yellow, 35-45 mm. long, minutely villosulose, the limb narrow; filaments inserted below middle of the tubular portion of corolla; capsule ovoid, acute, 1-1.2 cm. long, 4-valved at the summit; seeds reddish-brown, slightly shining, finely favose-reticulate. In sandy or clayey soils along stream banks, roadsides, on talus slopes and ledges along the coast and in extreme s. Tex., w. to the Trans-Pecos, flowering throughout the year; a nat. of S.A. that has become naturalized northw. to Tex. and Calif.

2. *Nicotiana repanda* Willd. FIDDLE-LEAF TOBACCO, WILD TOBACCO, TABACO CIMABRÓN. Annual, minutely pubescent or above glabrate, to about 9 dm. high, with loose slender branches extending into open racemose or somewhat paniculate naked inflorescences; leaves thin, ovate or the lower ones obovate and sometimes panduriform, commonly repand, to 2 dm. long and 1 dm. wide, rarely larger, the lowest leaves contracted into a winged petiole, the upper ones deeply cordate-clasping; bracts minute or often wanting; flowers; vespertine; calyx lobes slender, fully as long as the short-campanulate acutely 10-ribbed tube; corolla with tube frequently 5-6 cm. long, somewhat clavate or funnelform at the open throat; corolla limb spreading, white or sometimes tinged with rose, or dorsally brown-striped, to 4 cm. in diameter, its lobes short and obtuse or acute; capsule ovoid, about 1 cm. long, 4-valved; seeds brown, pitted-reticulate, shiny or dull. *N. Roemeriana* Scheele. In sandy or clayey soils along streams, on flats and in depressions, shelter of boulders, thickets and wooded ravines on the Edwards Plateau and in s. Tex., Feb.-July; also adj. Mex.

3. *Nicotiana trigonophylla* Dun. DESERT TOBACCO, TABAQUILLO. Biennial or perennial, viscid-pubescent, to about 9 dm. high, with a simple or virgately branched stem; leaves

¹⁷⁵ Ref.: Thomas H. Goodspeed, The Genus *Nicotiana*. 1954.

all sessile or only the lower ones tapering into a winged petiole and obovate-oblong, the upper ones elliptic-lanceolate to oblong-elliptic with a broader cordate half-clasping base, some spatulate-lanceolate with a dilated auriculate-clasping base, the largest leaves to about 22 cm. long and 6 cm. wide, rounded to acuminate at apex; inflorescence at length loosely paniculate-racemose, with the later bracts very small or wanting and somewhat unilateral pedicels about the length of the calyx; flowers open throughout the day; calyx lobes subulate-lanceolate but rather obtuse, shorter than or equaling the campanulate tube, attaining the middle of the corolla tube, about equaling the 4-valved capsule, somewhat callous-margined; corolla tubular-campanulate, greenish-white or yellowish, 12-23 mm. long, somewhat pubescent, a little constricted at the orifice, the tube slightly enlarging upward, the sinuately 5-lobed limb about 8 mm. in diameter; capsule ovoid, 8-11 mm. long; seeds brown, shining, pitted-reticulate. On breaks of arroyos and canyons, in gravelly-sandy soils on slopes, at base of boulders and on ledges of mesas and mts. in the Rio Grande Plains, South Plains and Trans-Pecos, Mar.-Nov.; from Tex., w. to Calif. and n. Mex.

4. *Nicotiana Tabacum* L. TOBACCO. Stout viscid annual (with us), usually about 2 m. high, erect, with few leafy branches; leaves decurrent, ovate to elliptic or lanceolate, the largest at least 5 dm. long, tapering or winged-subpetiolate at base, acute to acuminate at apex; flowers in a rather close panicle; calyx cylindrical-campanulate, 12-25 mm. long, the 5 unequal triangular-acuminate teeth shorter than or equaling the calyx tube; corolla tubular-campanulate, pale-cream-color, often tinged with pink or red, to about 5 cm. long, usually smaller, the limb 1-1.5 cm. wide; capsule narrowly elliptic to ovoid or globose, 1.5-2 cm. long; seeds spherical or broadly elliptic, brown, the ridges fluted. A nat. of Latin Am. that occasionally occurs as a waif in e. Tex.

This is the plant whose cured leaves constitute the "tobacco" of commerce.

5. *Nicotiana longiflora* Cav. LONG-FLOWERED TOBACCO. A vigorous annual or short-lived herbaceous perennial, to 1 m. high, sparsely branched, the slender stems sparingly pubescent, usually slightly tubercled and sometimes viscid; leaves in basal rosette to 5 dm. long, oblanceolate and subpetiolate to elliptic-ovate, the cauline leaves much smaller and sessile-auriculate; flowers vespertine, somewhat fragrant, racemose; calyx tubular, 1.5-2 cm. long, 10-ribbed, the 5 subulate segments usually equaling the tube; corolla tubular, pale-yellow, tinged with gray or purple, 4-12 cm. long, the limb 12-25 mm. across (the 5 lobes ovate and acute); capsule ovoid, 11-16 mm. long; seeds light-brown, with wavy-reticulate surface. A common garden plant, nat. of S.A., sometimes found as an escape in s.e. Tex.

6. *Nicotiana plumbaginifolia* Viv. Annual to about 1 m. high, the erect stem slender and tuberculate-hispid, with long basal branches; basal rosette leaves few, spatulate to obovate-spatulate or oblanceolate, hispid, to about 25 cm. long; cauline leaves progressively smaller and becoming lanceolate or linear-lanceolate to the widely branched inflorescence, sessile or clasping and auriculate at base, abruptly acuminate and somewhat twisted at apex, usually strongly undulate-plicate; flowers few, vespertine; calyx tubular, 8-13 mm. long, the long narrow segments subulate-filiform and about equal to the tube; corolla puberulent on outer surface, the slender tube 25-35 mm. long, greenish-white and lavender or purplish-tinged, the limb about 1 cm. wide and with ovate acute lobes; capsule narrowly ovoid, 8-11 mm. long; seeds light-brown with wavy-reticulate surface. In resacas in the Brownsville region (Cameron Co.), Jan.-Apr.; from Tex. through Mex., W.I. and C.A. to S.A.

FAM. 160. SCROPHULARIACEAE JUSS.¹⁷⁶ FIGWORT FAMILY

Mainly herbs, occasionally shrubs or rarely trees; leaves various; flowers perfect, in racemes or panicles, never terminal (in ours); sepals 4 or 5, free or united; corolla bilabiate or more or less irregular, rarely almost regular, the 4 or 5 lobes imbricated in bud; stamens didynamous, sometimes only 2 (rarely 5), inserted on the corolla tube; style single, the stigma entire or bilobed; capsule 2-celled and usually many-seeded, with the placentae in the axis; seeds anatropous or amphitropous.

¹⁷⁶ Unless otherwise noted, mostly adapted from publications by F. W. Pennell in Proc. Acad. Phila. 73:459-536. 1921; 92:289-308. 1940, and Mono. Acad. Phila. 1. 1935.

More than 3,000 species in about 220 genera of cosmopolitan distribution.

1. Corolla with the upper lobes external and overlapping in the bud (2)
1. Corolla with the lower lobes external and overlapping in the bud (19)
- 2(1). Stigmas distinct, usually flattened (except in *Scoparia* and *Bacopa Monnieri*); seeds reticulate, wingless; capsule walls membranous; inflorescence simply racemose, the bracts foliaceous (except in *Mazus*) and the flowers axillary; stamens 4, didynamous, or reduced to 2; leaves opposite or whorled (*Gratiolae*) (3)
2. Stigmas wholly united, punctiform or capitate; seeds not simply reticulate, either smooth, tuberculate, ridged or winged; stamens 4, didynamous, or 5 in *Verbascum* (13)
- 3(2). Cells of anther parallel; corolla with throat anteriorly rounded or flattened, obscurely or not ridged within; sepals distinct; pedicels often bibracteolate (4)
3. Cells of anther divergent; corolla with throat 2-ridged within anteriorly; sepals often united; pedicels never bracteolate (10)
- 4(3). Corolla rotate, yellow or white, densely pilose within on all sides, the lobes longer than the tube, the posterior 2 lobes united so as to simulate a single lobe; genitalia well-exserted 7. *Scoparia*, p. 1416.
4. Corolla campanulate, tubular or salverform, the lobes about equaling or shorter than the tube; genitalia not exserted (5)
- 5(4). Corolla campanulate, nearly regular, the lobes equaling or only slightly shorter than the tube, the posterior lobes united a little farther than the others; sepals unequal; stems creeping or floating, usually ascending at apex 1. *Bacopa*, p. 1412.
5. Corolla narrower than above, decidedly zygomorphic, the lobes distinctly shorter than the tube, the posterior lobes united for over half their length or throughout (6)
- 6(5). Leaf blades (at least some) pinnatisect, often bipinnatifid; pedicels not bracteolate; seeds commonly pale-greenish-yellow, nearly colorless; corolla pink or lavender (7)
6. Leaf blades entire or merely toothed; pedicels bibracteolate or (rarely in *Gratiola*) with bractlet single or lacking; seeds yellow to brown or blackish (8)
- 7(6). Plant terrestrial, the short bushy-branched stem erect; flowers numerous with slender pedicels 5 mm. long or more 5. *Leucospora*, p. 1416.
7. Plant aquatic, the elongate sparsely branched stem floating; flowers few, sessile 6. *Limnophila*, p. 1416.
- 8(6). Anther cells separated on short arms of the connective; corolla violet-blue; sepals uniform 4. *Stemodia*, p. 1415.
8. Anther cells proximate; corolla yellow or white; sepals usually somewhat unequal either in width or length (9)
- 9(8). Pedicels bibracteolate at the base; outer sepals much wider than the inner; fertile stamens 4; leaf blades pinnately veined 2. *Mecardonia*, p. 1413.
9. Pedicels bibracteolate at the apex; sepals nearly equal in width; fertile stamens 2; leaf blades palmately veined 3. *Gratiola*, p. 1413.
- 10(3). Filaments attached to the base of the corolla, always simple and both pairs antheriferous; capsule loculicidal; seeds more or less reticulate; sepals united; corolla 9-40 mm. long (11)
10. Filaments attached to corolla for most of length, the anterior each with a projecting knoblike process; capsule not loculicidal; seeds marked with fine transverse lines or smooth; sepals distinct or united (12)
- 11(10). Sepals united for over half their length; corolla yellow or violet, the posterior lip slightly shorter than the anterior and with its free lobes rounded; capsule 4-12 mm. long, longer than wide, quite enclosed within the erect calyx; bracts foliose 8. *Mimulus*, p. 1416.
11. Sepals united for less than half their length; corolla blue-violet, the posterior lip much shorter than the anterior and with its free lobes acute; capsule 2 mm. long, globose, distally exposed by the spreading calyx; bracts minute, subulate 9. *Mazus*, p. 1418.

- 12(10). Corolla violet-blue, 5-12 mm. long; the postero-lateral filaments present and antheriferous; capsule 1-6 mm. long, ellipsoid to ovoid, 2-celled, septicidal, the platelike septum persisting; sepals 5 10. *Lindernia*, p. 1418.
12. Corolla white, 1-2 mm. long; the postero-lateral filaments lacking; capsule 0.5-1 mm. long, globose, 1-celled (by lack of septum distally), rupturing irregularly; sepals 4 11. *Micranthemum*, p. 1419.
- 13(2). Capsule primarily septicidal, its walls firm or woody; corolla neither saccate nor spurred; shrubs or perennial herbs (14)
13. Capsule partly or wholly loculicidal; corolla saccate or spurred at base, strongly zygomorphic, yellow, blue or violet; perennial or annual herbs (17)
- 14(13). Leaves opposite; inflorescence simple or compound; posterior filament developed although lacking anther; corolla very strongly zygomorphic, variously colored; herbs, glabrous or with simple hairs (*Cheloneae*) (15)
14. Leaves alternate; inflorescence simple; filaments all with anthers; corolla only slightly zygomorphic; plants often with stellate hairs (16)
- 15(14). Sterile filament slender, filiform; corolla rarely less than 15 mm. long, the anterior lobes spreading; sepals distinct 14. *Penstemon*, p. 1421.
15. Sterile filament flattened, nearly as wide as or wider than long; corolla 6-12 mm. long, the antero-lateral lobes vertically projecting and its mid-anterior lobe deflexed; inflorescence compound, relatively lax, the flowers disposed in peduncled cymes 15. *Scrophularia*, p. 1425.
- 16(14). Corolla rotate, yellow, purple or white, not spotted, its lobes longer than the tube; anther cells wholly confluent; filaments 5, at least the posterior villous; inflorescence a raceme or spike; herbaceous (*Verbasceae*) 12. *Verbascum*, p. 1419.
16. Corolla campanulate, purple, deep-pink or rarely white, usually marked with orange within throat, its lobes shorter than the tube; anther cells distinct; filaments 4, glabrous; flowers remote, axillary; much-branched shrub (*Leucophylleae*) 13. *Leucophyllum*, p. 1420.
- 17(13). Leaves opposite; corolla pouched at base posteriorly, the mid-anterior lobe sagittally folded, the antero-laterals flattened and the much paler or white posterior lobes erect; capsule thin-walled, longitudinally dehiscent septicidally and loculicidally (*Collinsieae*) 16. *Collinsia*, p. 1426.
17. Leaves alternate; corolla pouched or spurred at base anteriorly, the anterior lobes plane or usually raised medianly into a ridged palate, the posterior lobes ascending but not differently colored; capsule dehiscing by transverse loculicidal ruptures (*Antirrhineae*) (18)
- 18(17). Seeds angled or with thin wings; leaf blades entire or hastate-lobed at base, pinnately veined; corolla violet-blue or yellow, spurred; stems erect 17. *Linaria*, p. 1426.
18. Seeds with several thick corky wings; leaf blades palmately veined and lobed; corolla violet-blue, its orifice closed by a yellow palate; stems climbing or extensively trailing 18. *Maurandya*, p. 1427.
- 19(1). Upper lobes of corolla flattened or widely arched, often spreading; anthers all distinct (20)
19. Upper lobes of corolla narrowly arched to form a definite galea that encloses the anthers; stigmas wholly united; anthers frequently cohering, the pollen being shed in a mass; stamens 4, didynamous; capsule loculicidal (except in *Schwalbea*); commonly root-parasites (*Euphrasieae*) (27)
- 20(19). Stamens 2, the postero-lateral pair alone developed; corolla 2-5 mm. long, the posterior lobes wholly united; plants not parasitic (*Veroniceae*) (21)
20. Stamens 4, didynamous; corolla 7 mm. long or more, the lobes all evident; root-parasites (*Buchnereae*) (22)

- 21(20). Capsule acute, much longer than wide, slightly flattened, dehiscent by short apical septical and loculicidal slits; seeds turgid, slightly reticulate; corolla lobes much shorter than the tube; plant 1-2 m. high, with leaves in whorls of 3 to 5 19. *Veronicastrum*, p. 1427.
21. Capsule rounded to deeply notched, little (if at all) longer than wide, flattened, dehiscent by longer loculicidal slits; seeds more or less flattened, smooth; corolla lobes nearly as long as or usually longer than the tube; plants lower, with leaves opposite or alternate 20. *Veronica*, p. 1428.
- 22(20). Stamens with only one anther cell developed, the other wholly abortive; corolla salverform, blue to violet-purple or white, the throat very narrow and filled with short stiff hairs; filaments and style less than half the length of the corolla tube; capsule nearly or quite included in the calyx tube; pedicel bibracteolate 26. *Buchnera*, p. 1438.
22. Stamens with both anther cells equally developed; corolla neither salverform nor blue, its throat wide; filaments and style nearly as long as or longer than the corolla tube; capsule partly or nearly wholly exerted from the calyx; pedicel not bracteolate (23)
- 23(22). Anther cells glabrous or rarely with a few bristlelike hairs at apex; corolla semi-rotate, 7-16 mm. long; stigma punctiform or capitate (24)
23. Anther cells villous; corolla semicampanulate, 10-60 mm. long; stigma somewhat elongate (25)
- 24(23). Corolla densely pubescent within on all sides; filaments clearly didynamous; anther cells somewhat cuspidate at base, each opening its entire length; styles short, thick, distally parted, persistent and reflexed on the capsule; pedicels 1-2 mm. long; plant stout, 15-20 dm. high, the leaves large 22. *Dasistoma*, p. 1431.
24. Corolla glabrous or nearly so (except about the bases of the nearly equal filaments); anther cells obtuse at base, each opening less than half of its length; styles slender, united to apex, deciduous, straight; pedicels usually longer; plants lower, the leaves relatively small 23. *Seymeria*, p. 1431.
- 25(23). Corolla yellow; anther cells with rigid awns at base; stigma ovoid-capitate; capsule acute to acuminate; leaf blades lanceolate to ovate, entire to bipinnatifid 21. *Aureolaria*, p. 1429.
25. Corolla purple or pink, nearly always with red-purple spots within on anterior side; anther cells rounded or mucronate-setaceous at base; stigma linguiform; capsule rounded, with a mucro; leaf blades or segments lanceolate to linear or subulate (26)
- 26(25). Leaf blades lanceolate to ovate in outline, usually lobed at base or bipinnatifid; calyx lobes ovate to widely lanceolate, longer than the tube; corolla without yellow lines within throat; anther cells of posterior pair of stamens smaller; reticulations of seed coat somewhat raised; stem retrorse-hispid . . 24. *Tomanthera*, p. 1432.
26. Leaf blades lanceolate to filiform or subulate, entire or sometimes lobed at base (in *A. heterophylla*); calyx lobes linear to subulate, about as long as to much shorter than the tube; corolla usually with 2 yellow lines within throat on anterior side; anther cells of both pairs of stamens equal; reticulations of seed coat not raised; stem ascending-scabrous to glabrous 25. *Agalinis*, p. 1433.
- 27(19). Pedicel bibracteolate; calyx lobes 5; capsule turgid, septical and tardily also somewhat loculicidal; seeds narrow, winged . . . 27. *Schwalbea*, p. 1438.
27. Pedicel not bracteolate; calyx lobes 4; capsule loculicidal; seeds wide (28)
- 28(27). Cells of anther equal in size and position; seed coat close, not obviously reticulate (29)
28. Cells of anther unequally placed, the upper one attached by its middle; seed coat loose, evidently reticulate (30)

- 29(28). Capsule symmetrical, both cells dehiscent equally; anther cells mucronate-tipped; stem leaves sessile and clasping 28. *Parentucellia*, p. 1439.
29. Capsule asymmetrical, usually decurved, opening on the distal side; anther cells not mucronate-tipped; stem leaves prominently petiolate 29. *Pedicularis*, p. 1439.
- 30(28). Calyx tube surrounding the proximal portion of the corolla, its 4 (or by fusion 2) lobes laterally placed 30. *Castilleja*, p. 1439.
30. Calyx tube surrounding base of corolla or usually wholly to its dorsal side, extending as a narrow linguiform dorsal structure that is entire or only slightly bidentate at apex 31. *Cordylanthus*, p. 1442.

1. BACOPA AUBL.

WATER-HYSSOP

Low succulent perennial herbs; flowers axillary; calyx 5-parted, the uppermost divisions broadest, the innermost often very narrow; upper lip of corolla entire to notched or 2-cleft and the lower lip 3-lobed or the limb almost equally 5-lobed; style dilated or bilobed at apex; seeds numerous.

About 100 species, primarily in warm regions.

1. Leaves cuneate to narrow bases, 1-nerved; pedicels much-exceeding the subtending leaves, conspicuously 2-bracted below the calyx ... 1. *B. Monnieri*.
1. Leaves rounded to broad or more or less clasping bases, 3- or more-nerved; pedicels mostly shorter than the subtending leaves (2)
- 2(1). Leaves ovate, pellucid-punctate; flower usually closely subtended by a pair of minute bractlets; ovary surrounded by a slenderly 10- to 12-toothed disk; upper lip of corolla obcordate 2. *B. caroliniana*.
2. Leaves suborbicular to broadly obovate, not obviously punctate; flowers not subtended by bractlets; disk at base of ovary none or without slender teeth; upper lip of corolla merely emarginate 3. *B. rotundifolia*.

1. *Bacopa Monnieri* (L.) Wettst. Plant with prostrate to decumbent or loosely ascending stems, forming mats, fleshy, glabrous; leaves spatulate to cuneate-obovate, obtuse to rounded at apex, entire or nearly so, to about 2 cm. long; flowers single in nodes, with 2 linear bracts at base of calyx; pedicels to 25 mm. long, soon exceeding the subtending leaves; larger sepal lanceolate to ovate, to 5 mm. wide; corolla campanulate, only obscurely bilabiate, white to lilac or pale-blue, 8-10 mm. long, glabrous within; capsule slenderly conic to ovoid, 5-7 mm. long, shorter than the calyx. Incl. var. *cuneifolia* Fern., *Bramia Monnieri* (L.) Penn. In mud and sand in depressions among dunes, about ponds, along streams and ditches in e., cen. and s. Tex., Apr.-Sept.; from Fla. to Tex., n. to Va.

2. *Bacopa caroliniana* (Walt.) Robins. BLUE HYSSOP. Stems from creeping rhizome, floating or ascending, to about 4 dm. high, lanate at summit; plant (when bruised) lemon-scented; leaves in subapproximate pairs, ovate to ovate-elliptic, obtuse, clasping, to 25 mm. long, entire, pellucid-punctate, fragrant, the nerves pedately radiating from base; flowers single, scarcely exerted beyond leaves, with short pedicels; calyx often with 2 minute subulate basal bracts, the outer sepal cordate; corolla blue, about 1 cm. long, pubescent within, its upper lip obcordate; ovary surrounded by a slenderly 10- to 12-toothed disk; capsule ovoid, acute, about 5 mm. long. *Hydrotrida caroliniana* (Walt.) Small. On margins of ponds and streams, and in bogs in pinelands in e. Tex., May-Oct.; from Fla. to Tex., n. to Va.

3. *Bacopa rotundifolia* (Michx.) Wettst. DISC WATER-HYSSOP. Plant creeping, with elongate and lax terminally pubescent branches to 6 dm. long, forming mats on mud or attached and floating; leaves thin, suborbicular to broadly obovate, with subcuneately narrowed but clasping bases, clearly palmately many-nerved, the larger ones to 35 mm. long and 25 mm. wide; flowers usually 2 to 4 from upper nodes; pedicels 2 or 3 times as long as calyx, slender, pubescent, to 2 cm. long; outer sepals ovate, 6-8 mm. long; corolla exerted, campanulate, 6-10 mm. long, the wide-spreading limb about as broad, white, with yellow throat; capsule globose to subglobose, about as long as sepals. *Macuillamia*

rotundifolia (Michx.) Raf. In mud and water in and about lakes, pools, ditches and ponds throughout Tex., May-Nov.; from Miss. to Tex., n. to Ind., Ill., Minn., N.D. and Mont.

2. MECARDONIA R. & P.

Erect or diffuse much-branched glabrous herbs from a perennial root, often becoming black upon drying; stems 4-angled; leaves opposite, narrowed to a sessile base, toothed, glandular-punctate; flowers axillary in leaflike bracts; bractlets 2, at the base of the slender pedicel and much shorter than the bracts; sepals 5, unequal, the outer ones much wider than the inner ones; corolla bilabiate with the lobes shorter than the tube, the posterior lip more or less united and pubescent within at base; stigmas liplike; capsule cylindrical to ovoid, acute, glabrous, septicial, the valves only slightly loculicidal at apex; seeds numerous, cylindrical, reticulate, wingless.

About a dozen species in warmer parts of America.

- 1. Corolla yellow, its upper bearded lobes essentially united or forming only a slightly notched lamina; 3 outer sepals broadly ovate to ovate-elliptic, more than 3 times as wide as the 2 inner sepals; leaves typically ovate or oval, abruptly cuneate at base, less than 25 mm. long; plant procumbent or ascending 1. *M. vandellioides*.
- 1. Corolla white, often with purplish stripes, its upper bearded lobes typically separated at least one third their length, 3 outer sepals lanceolate, rarely more than 2 times as wide as the 2 inner sepals; leaves typically oblanceolate, tapering to the narrow base, more than 3 cm. long; plant erect or diffusely branched 2. *M. acuminata*.

1. *Mecardonia vandellioides* (H.B.K.) Penn. Plant very variable, glabrous throughout; stems procumbent to erect-ascending, often branched and widely spreading from the base, to about 4 dm. long; leaves opposite, sessile, ovate to oval or obovate-oblong, obtuse to subacute, more or less serrate or serrulate above the middle, 1-2.5 cm. long; pedicels axillary, solitary, usually noticeably exceeding the subtending leaf and the 2 small basal bracteoles; calyx 5-parted, the 2 interior lobes linear, the 3 outer lobes broadly ovate to ovate-elliptic, acutish, sometimes serrulate above the middle; corolla 6-12 mm. long, always longer than the calyx, bilabiate, yellow with longitudinal dark veins on the essentially united upper pair of lobes; capsule ellipsoid, about as long as or shorter than the calyx. *M. procumbens* (Mill.) Small, *M. peduncularis* (Benth.) Small, *M. viridis* Small, *M. montevidensis* (Spreng.) Penn., *Pagesia peduncularis* (Benth.) Penn., *P. vandellioides* (H.B.K.) Penn. In mud and water of ditches, lagoons, ponds and streams, and in moist soils of depressions, mostly in cen., s. and w. Tex., Mar.-Nov.; from Fla. to Tex., Ariz. and Mex., s. to s. S.A.

2. *Mecardonia acuminata* (Walt.) Small. Stems from a subligneous crown, erect or ascending, glabrous, simple to branched, to about 7 dm. high; leaves oblanceolate to oblong-lanceolate, mostly narrowly obtuse, tapering below to a narrowly cuneate base, firm, serrate above the middle, mostly 2-4 cm. long; pedicels filiform, equaling or surpassing the subtending leaves and 2 small basal bractlets; outer 3 sepals oblong-lanceolate, broader than the lanceolate inner 2 sepals; corolla white, often tinged or lined with purple, 7-10 mm. long, bearded within at the base of the upper obviously bilobulate lip. *Bacopa acuminata* (Walt.) Robins., *Pagesia acuminata* (Walt.) Penn. In ditches, bogs, depressions in fields and prairies, swamps and flat pinelands in e. Tex., Aug.-Oct.; from Del. and Md., s. to Fla., Tex. and Mo.

3. GRATIOLA L. HEDGE-HYSSOP

Low mostly perennial or some biennial or annual herbs; leaves sessile; two (rarely 1) bractlets usually at base of calyx; the 5 narrow divisions of calyx more or less subequal; corolla tubular or narrowly campanulate, bilabiate; upper lip of corolla entire or 2-cleft, the lower lip 3-cleft; style dilated or bilabiate at apex; capsule 4-valved, many-seeded.

About 20 species that are widely distributed.

1. Plant villous-hirsute; anthers with contiguous vertical cells; flowers subsessile; calyx lobes very unequal; corolla only slightly exceeding the calyx 1. *G. pilosa*.
1. Plant glabrous or at most puberulent; anthers with a broad connective, the cells transverse; flowers mostly distinctly pedicellate; calyx lobes equal or nearly so; corolla much-exceeding the calyx (2)
- 2(1). Capsule 1-3 mm. long, much-exceeded by the calyx lobes; cauline leaves clasping by a wide base, usually at least the upper with resinous dots; rhizomes perennial, slender, stoloniferous 2. *G. brevifolia*.
2. Capsule 3-6 mm. long, equal to or only slightly exceeded by the calyx lobes; cauline leaves narrowed to a sessile or scarcely clasping base, obscurely glandular-punctate; roots annual, the main root thick and producing many fibers (3)
- 3(2). Corolla golden-yellow (especially the limb); capsule ovoid-pyramidal, nearly twice as long as calyx lobes; stem less than 1 dm. high, thin, not fleshy; in central and south Texas 3. *G. flava*.
3. Corolla white (at least as to the limb); capsule globose to globose-ovoid, nearly or quite equaled by the calyx lobes; stems usually more than 1 dm. high, relatively thick and fleshy, mostly in east Texas (4)
- 4(3). Pedicels slender, over 1 cm. long; hairs on upper side of corolla throat clavate; capsule 4-5 mm. long, globose-ovoid, about equal to the calyx lobes 4. *G. neglecta*.
4. Pedicels stout, mostly much less than 1 cm. long; hairs on upper side of corolla throat filiform; capsule globose, usually slightly exceeding the calyx lobes 5. *G. virginiana*.

1. *Gratiola pilosa* Michx. HAIRY HEDGE-HYSSOP. Perennial, the firm tufted stems from a subligneous crown, villous-hirsute, to 75 cm. high; leaves sessile by broad rounded clasping bases, to about 2 cm. long, ovate to ovate-lanceolate, crenate-serrate; flowers subsessile or very short-stalked in the axils; calyx segments very unequal; corolla white or purple-tinged, 5-9 mm. long, little-exceeding the calyx; anthers with contiguous vertical cells; capsule 4-5 mm. long, slenderly conical. *Sophronanthe pilosa* (Michx.) Small, *Tragiola pilosa* (Michx.) Small & Penn. In bogs, swamps and moist sandy woods in e. third of Tex., June-Aug.; from Fla. to Tex., n. to N.J., Md., N.C., Ky., Ark. and Okla.

2. *Gratiola brevifolia* Raf. STICKY HEDGE-HYSSOP. Annual or short-lived perennial, puberulent and somewhat viscid, to about 35 cm. high; leaves lanceolate to linear-lanceolate, acute to acuminate, sparsely and acutely serrate, to 35 mm. long and 1 cm. wide, equal to or shorter than the pedicels; sepals and bractlets linear-subulate, much longer than the capsule; corolla whitish, 1-1.2 cm. long; sterile filaments short. *G. ramosa* [var.] *Drummondii* (Benth.) Penn., *G. Drummondii* Benth., *Ilysanthes inaequalis* (Walt.) Penn. In bogs, marshes, wet meadows and in and on the edge of water in ponds and lakes in e. Tex., Apr.-Sept.; from Ga. to Tex. and Ark.

3. *Gratiola flava* Leavenw. GOLDEN HEDGE-HYSSOP. Annual, glabrous throughout, less than 1 dm. high, the slender stems clustered at base and erect-ascending; leaves few, opposite, linear-oblancoate, entire or with few obscure serrations, to 15 mm. long and 5 mm. wide, clasping at the sessile base, obtuse at apex; bracteole 1, linear-spatulate, about as long as the sepals; calyx lobes 3-5 mm. long, linear to linear-lanceolate, obtuse; corolla with orange-yellow tube and golden-yellow limb, about 12 mm. long; capsule brown, ovoid-pyramidal, noticeably exceeding the sepals; seeds brown, with coarse reticulations. *G. pusilla* Torr. In sandy soil in prairies and fields in cen. and s. Tex., Feb.-Apr.; also La.

4. *Gratiola neglecta* Torr. Annual with simple or loosely branched soft stem to 4 dm. high, the upper internodes, pedicels and expanding leaves more or less clammy-puberulent; leaves thin, rhombic-lanceolate to lanceolate, tapering to base and apex, undulate-dentate or entire, to 55 mm. long; pedicels filiform, elongating to 25 mm. long; bractlets foliaceous, equal to or exceeding the calyx; corollas honey-color to creamy-white, with yellowish tube, the earlier ones 8-12 mm. long, the inside of the throat with clavate beard-

ing; sterile stamens minute or none; capsule 3-5 mm. long, globose-ovoid; seeds thick-cylindric, about 0.5 mm. long. *G. gracilis* Benth., *G. Torreyi* Small. In wet or muddy places about ponds and in woods in e. third of Tex., Mar.-June; from Que. and Me. to B.C., s. through most of the U.S.

5. *Gratiola virginiana* L. Rather coarse plant, the fleshy base often biennial; stems simple or with few ascending branches, to 45 cm. high, usually glabrous; leaves lanceolate to elliptic or oblong-obovate, shallowly undulate to sharply serrate, to 7 cm. long; pedicels stoutish, usually less than 5 mm. long; calyx 4-8 mm. long; corolla milk-white or pink-tinged to honey-colored, the earlier ones to 15 mm. long, with filiform hairs inside at throat; capsule globose, slightly exceeding to shorter than the calyx, 4-7 mm. long; seeds slender-cylindric, about 0.8 mm. long. In water of streams, lakes, ponds and ditches, in boggy areas and in open flats in forest in e. third of Tex., Mar.-May; from Fla. to Tex., n. to N.J., Md., W.Va., O., Ind., Ia. and Kan.

4. STEMODIA L.

Herbs or low shrubs, mostly glandular-pubescent and odorous; leaves opposite or verticillate, sessile and clasping; flowers solitary in axils or in terminal often leafy-bracted spikes or racemes; pedicels 2-bracteolate; calyx 5-parted, the imbricated sepals nearly distinct and equal; corolla with a subcylindric tube and a bilabiate limb, the erect upper lip notched or entire, the lower lip 3-lobed; stamens 4, didynamous, included; filaments filiform, the anther sacs distinct and stipitate; capsule attenuate, bivalved, the valves 2-cleft; seeds small, striate, tuberculate.

About 30 species, mostly in tropical regions.

1. Foliage white-woolly; stems and branches prostrate or procumbent, often long-trailing; flowers essentially sessile 1. *S. tomentosa*.
1. Foliage merely minutely glandular-pubescent, viscid; stems and branches erect or ascending; flowers distinctly pedicellate (2)
1. Foliage white-woolly; stems and branches prostrate or procumbent, often long-trail-narrowly lanceolate; corolla less than 1 cm. long ... 2. *S. durantifolia*.
2. Stems and branches weakly ascending; leaves of a cuneate type, obtuse; calyx lobes linear; corolla more than 1 cm. long 3. *S. Schottii*.

1. *Stemodia tomentosa* (Mill.) Greenm. & Thomps. WOOLLY STEMODIA. Perennial, the herbage white woolly-lanose, not glandular; stems more or less branched with the branches prostrate or procumbent, often long-trailing and rooting at nodes, to 4 dm. long or more; leaves oblong-elliptic to elliptic-obovate, cordate and clasping at base, obtuse to rounded at apex, the upper margins dentate to crenate-serrate, to 4 cm. long, usually much smaller; flowers nearly sessile; bractlets subulate, much less than half as long as the subulate calyx lobes; corolla 7-8 mm. long, purplish or bluish-purple, the throat whitish with violet veins; seeds black, ovoid. *S. lanata* R. & P. In dunes and sandy soils on slopes, in scrublands and plains, mainly along the coast and in the Rio Grande Plains of s. Tex., rare in s. Trans-Pecos, Apr.-Aug.; also adj. Mex.

2. *Stemodia durantifolia* (L.) Sw. Annual, glandular-pubescent, rather rigidly erect, often much-branched, the branches slender, to about 9 dm. high; leaves sessile and amplexicaul, opposite or several at the nodes, oblong-elliptic to linear-oblong or linear-lanceolate to oblanceolate, the upper ones linear, acute to acuminate or obtuse at apex, serrate or serrulate, those of the stem to 9 cm. long, with narrowed bases; flowers nearly sessile, solitary in the axils or in spiciform leafy-bracted racemes; bractlets 2, linear, shorter than the calyx; sepals about 5 mm. long, lanceolate, acuminate; corolla blue or purple, glandular-pubescent, longer than the calyx. In wet soil along streams in s. Tex., Feb.-Oct.; from Calif. to Tex., southw. in Latin Am.

3. *Stemodia Schottii* Holz. Annual with woody base or perennial, to about 25 cm. high, diffusely slender-branched with the stem and branches weakly spreading-ascending, minutely stipitate-glandular throughout, viscid; leaves sessile, narrowly cuneate to cuneate-obovate and more or less auricled at the clasping base, coarsely toothed above the base, obtuse at apex, 2 cm. long or less; flowers single in axils of upper leaves that are only slightly (if at all) smaller than those on lower part of stem; pedicels 3-5 mm. long,

with 2 linear bracts below calyx; calyx lobes narrowly linear, about as long as pedicel; corolla 12-15 mm. long, the tube dilated upward, blue at the limb, yellow on the underside and toward base of tube, somewhat hairy on inner surface, the large upper lobe outermost; longer pair of stamens reaching the small notches in the corolla limb; capsule slightly shorter than calyx lobes; seeds light-brown, cylindric. In open thickets, roadside ditches and fields in s. Tex., throughout the year; also Tam.

5. LEUCOSPORA Nutt.

A monotypic genus.

1. *Leucospora multifida* (Michx.) Nutt. Low much-branched annual herb, diffusely spreading, to about 2 dm. high and about as wide, puberulent throughout; leaves opposite, petioled, triangular-ovate in outline, 2-3 cm. long, pinnately parted, the divisions oblong to linear-cuneate; pedicels naked, solitary in axils, 5-10 mm. long; calyx 5-parted, the sepals linear; corolla tubular, bilabiate, pale-lavender, about 4 mm. long, scarcely exceeding the calyx, upper lip bilobed, the lower lip 3-parted; anthers approximate; stigma bilobed, the lobes cuneiform; capsule ovoid, septicial, many-seeded. *Conobea multifida* (Michx.) Benth. In mud and sand-gravel along streams and on shores, mostly in cen. and e. Tex., June-Oct.; from Ont. to Ia. and Kan., s. to Ga., Ala., La. and Tex.

6. LIMNOPHILA R. BR.

About 30 species that are native mainly in Africa and Australia.

1. *Limnophila sessiliflora* Bl. Aquatic glabrous herbs with mostly branched leafy stems that are to 5 dm. long or more; leaves 3 to 6 in a whorl, all pinnatisect or the uppermost opposite, linear-spatulate and toothed, gland-dotted, usually 2-2.5 cm. long; flowers axillary, solitary, sessile or very shortly pedicelled; calyx about 8 mm. long, with 5 ovate acuminate lobes, the tube hemispheric in fruit; corolla about 12 mm. long, pink or lavender-pink, bilabiate, the upper lip entire or bifid, the lower lip nearly equally 3-lobed and spreading, the tube cylindric; capsule orbicular, swollen, about 5 mm. thick. Attached to bottom of lake and in current of river at San Marcos (Hays Co.) where it has been introd. and has become well-established, July-Nov.; a nat. of Asia.

7. SCOPARIA L. BROOMWORT

About 20 species, mostly in tropical America.

1. *Scoparia dulcis* L. SWEET BROOMWORT. Annual, glabrous, to 1 m. high, often much-branched, the branches slender; leaves short-petioled, ovate to elliptic-lanceolate, opposite or verticillate in threes or fours, coarsely serrate or the upper ones subentire, acute at apex, narrowed or cuneate at base, punctate, the lower leaves 2-4 cm. long; pedicels filiform, as long as the upper leaves or shorter, often borne in most of the axils; sepals 4, oblong to oblong-obovate, acute, sometimes ciliate, about 1.5 mm. long; corolla white or light lavender, 3-4 mm. broad, essentially rotate, 4-cleft, densely bearded in throat, its obtuse lobes nearly equal; stamens 4, subequal, the filaments filiform, the distinct anther sacs parallel or divergent, style clavate above, the stigma truncate or notched; capsule globose-ovoid, slightly longer than sepals, septically dehiscent, its entire valves membranous; seeds numerous, angular. In disturbed soils and moist or dry soils in open woods in e. Tex., Apr.-Nov.; from s. U.S. to S.A.; also Old World trop.

8. MIMULUS L.¹⁷⁷ MONKEY-FLOWER

Herbs (in ours) with perennial rhizomes or stolons; flowers axillary; calyx tubular, angled or prismatic, regular or irregular, the lobes shorter than the tube; corolla

¹⁷⁷ Adapted mainly from Adele L. Grant in Ann. Missouri Bot. Gard. 11:99-388. 1924.

irregular, bilabiate; lobes of upper corolla lip erect to reflexed; lobes of lower corolla lip spreading or deflexed, arched in the throat or with 2 elevated ridges partially or completely closing the orifice; stamens 4, didynamous, inserted near middle of corolla tube, the anthers approximate in pairs with their sacs divergent; style elongate, the stigmas 2 and platelike; capsule cylindric, loculicidal, many-seeded.

More than 100 species that are world-wide in distribution, mostly in western United States.

1. Corolla blue to white; calyx teeth essentially equal; distribution in east Texas (2)
1. Corolla yellow or purple-red; calyx teeth usually unequal with the posterior tooth larger than the others; distribution in central and west Texas (3)
- 2(1). Leaves mostly sessile; pedicels more than one half as long as the leaves 1. *M. ringens*.
2. Leaves petioled; pedicels mostly less than one half as long as the leaves 2. *M. alatus*.
- 3(1). Leaves mostly suborbicular, more or less covered with short stiff white hairs; corolla laciniately lobed or erose 3. *M. dentilobus*.
3. Leaves broadly ovate to suborbicular or elliptic-lanceolate, glabrous or nearly so; corolla lobes mostly entire (4)
- 4(3). Calyx lobes ciliate, equal; corolla about 8 mm. long, purple-red or yellow; cauline leaves elliptic-oblong to elliptic-lanceolate, narrowed to a sessile base; stem and pedicels glandular-puberulent 4. *M. rubellus*.
4. Calyx lobes not ciliate, the posterior one longest; corolla 9-16 mm. long, yellow; cauline leaves broadly ovate to suborbicular, the larger conspicuously petioled; stem and pedicels glabrous 5. *M. glabratus*.

1. *Mimulus ringens* L. Perennial by stoloniferous rootstocks, glabrous; stems simple or branched, 4-angled, to 13 dm. high; leaves thin, oblong to oblong-lanceolate, to 1 dm. long and 3 cm. wide, acute to obtuse at apex, tapering to a broad often auriculate-clasping sessile base, serrate to rarely entire; pedicels stout, to 35 mm. long, mostly shorter than the subtending leaves; calyx tubular, 14-17 mm. long, strongly angled, with slender subulate or aristate teeth about one fourth as long as tube, with broad ciliate sinuses; corolla 25-35 mm. long, blue, rarely pink or white, the exerted tube slightly funnellform, the throat nearly closed, upper lip erect and strongly reflexed, lower lip longer and the stigma broadly bilamellate; capsule included, broadly oblong; seeds oblong, papillate, spreading with the margins erose; upper pair of stamens slightly exerted; style exerted, the stigma broadly bilamellate; capsule included, broadly oblong; seeds oblong; papillate. In wet places in n.e. Tex., June-Sept.; from Can. to Fla., w. to N.D. and s. to Okla. and (?) Tex.

Reported from Texas but no material seen. It should be looked for in some of the marsh areas in northeast Texas.

2. *Mimulus alatus* Ait. Stems stoloniferous, glabrous, simple or branched, to 7 dm. high, 4-angled, the angles more or less winged; leaves broadly ovate to ovate-lanceolate, acute, to 15 cm. long and 6 cm. wide, serrate, tapering to a narrow-margined petiole to 25 mm. long; pedicels stout, mostly shorter than the calyx; calyx oblong, 14-17 mm. long, with sharp angles, the broad mucronate teeth about 1.5 mm. long; corolla blue or violet, sometimes tinged with pink or rarely white, 2-2.5 cm. long, the tube slightly exerted, the throat nearly closed, lobes of the upper lip erect and strongly reflexed, the lower lip longer and spreading; stamens and style included; capsule ovoid, obtuse; seeds oval, papillate. In wet areas (especially along wooded streams) in e. Tex., w. to Blackland Prairies, June-Nov.; from Mass., s. to S.C. and w. to Tex.

3. *Mimulus dentilobus* Robins. & Fern. Low creeping plants, rooting from the nodes and forming dense mats, the terete stems nearly glabrous or sparsely pubescent, to 5 cm. high; leaves broadly ovate to suborbicular, 2-7 mm. long, 2-5 mm. wide, dentate to crenate or nearly entire, mostly with winged petioles shorter than the blade, more or less covered with stiff white hairs; flowers few, axillary or terminal; pedicels slender, almost filiform, pubescent, much-exceeding the leaves; mature calyx turbinate, 5-7 mm. long, sparsely pubescent or rarely glabrous, with triangular acute teeth; corolla 9-13 mm.

long, the throat spotted with red below the lower lip, the lobes erose or somewhat lacinate; style puberulent or glabrous; capsule oblong, less than half as long as calyx, compressed; seeds brownish, oval, sometimes 3-sided, longitudinally striate and often bearing stiff scattered hairs. In permanently wet places in mts. of the Trans-Pecos, June-Aug.; from w. Tex. and N.M. to n. Mex.

4. *Mimulus rubellus* Gray. Annual, glandular-puberulent to almost glabrate, the erect stems often much-branched, to 2 dm. high; leaves sessile or with the lowest smaller and petioled, elliptic-oblong to elliptic-lanceolate, entire or only slightly toothed, 3-veined, to about 2 cm. long; pedicels to 22 mm. long; calyx 5-9 mm. long, often reddish, ridge-to wing-angled, its ciliate lobes low-triangular or its mucronate tips less than 0.5 mm. long; corolla yellow throughout or the lobes purple-red, 7-9 mm. long, the throat narrow, ventrally 2-ridged and puberulent, the orifice open and the slightly spreading lobes notched; anthers glabrous; capsule 4 mm. long, not dehiscing through septum apex. In moist or wet places in extreme w. Tex., Apr.-June; from w. Tex., N.M. and s. Colo. to Calif.

5. *Mimulus glabratus* H.B.K. Low perennial, glabrous or nearly so, stoloniferous or with creeping stems that root freely at the lower nodes; stems usually numerous, hollow, weak, to 75 cm. long; leaves broadly ovate to suborbicular, to 7 cm. long and 6 cm. wide, irregularly dentate, sometimes shallowly lobed at the base, 3- or 5-nerved, the basal leaves cuneate to subcordate or with margined petioles at base, upper leaves subcordate at the sessile base; flowers axillary, mainly on upper part of stem; pedicels slender, glabrous or pubescent, longer or shorter than leaves; calyx campanulate, often spotted or tinged with red, to 1 cm. long, glabrous or pubescent, larger in fruit, the broad short unequal teeth spreading; corolla tubular, to 15 mm. long, the tube slender, lower lip heavily bearded, middle lobe much longer than the lateral ones; style glabrous; capsule oblong, rounded, constricted at the base but not stipitate, shorter than the calyx tube; seeds oval, longitudinally striate. Incl. var. *Fremontii* (Benth.) Grant. In shallow water of streams or muddy places with the stems often floating or creeping and more or less procumbent, on the Edwards Plateau and in the Trans-Pecos, throughout the year; from Ont. and Man., s. to Tex., Nev. and Mex.

9. MAZUS LOUR.

About 20 species, all Australasian.

1. *Mazus japonicus* (Thunb.) O. Ktze. Plants slender, loosely pubescent, to about 2 dm. high; leaves opposite, mostly basal or near base of stem, obovate to cuneate-oblong, coarsely few-dentate, the radical leaves 2-5 cm. long; racemes loosely 2- to 7-flowered, terminal, subsecund, with minute or obsolete bracts and ebracteolate or minutely bracteolate alternate pedicels 5-7 mm. long; calyx lobes 5, ovate-lanceolate, equaling the campanulate tube; corolla 7-10 mm. long, scarcely twice the length of calyx, with slightly bifid erect upper lip, the 3-lobed lower lip much larger, with 2 gibbosities at throat, blue, the yellow or whitish palate bordered by reddish-brown; style with 2 ovate lobes; fertile stamens 4, the contiguous anther cells divaricate; capsule 3-4 mm. long, somewhat globose, shorter than calyx, with 2 entire valves. In grasslands and along roadsides in e. Tex., Mar.-Oct.; from Pa. to Mo., La. and Tex.; also Pac. slope; naturalized from e. Asia.

10. LINDERNIA ALL.

FALSE PIMPERNEL

Diffuse annual herbs; leaves opposite, denticulate to nearly entire; bracteoles none; flowers in axils of most leaves; sepals 5, distinct; corolla blue-violet, bilabiate, the upper lip with 2 short erect acutish lobes, the lower lip much larger and spreading, with 2 hairy yellow ridges within the throat; filaments 4, didynamous, the upper short and antheriferous, the lower forming the hairy ventral ridges of the corolla and projecting from apex as sterile knobs; stigmas distinct, lamelliform; capsule septicidal, ovoid to ellipsoid, the septum persisting as a thin plate; seeds smooth or finely lined transversely.

About 80 species, mainly in warm regions of Asia and Africa.

- 1. Lower pedicels shorter than their subtending leaves; main leaves obovate to elliptic or ovate, rounded or narrowed to base; capsule often equaled or exceeded by the calyx lobes1. *L. dubia*.
- 1. Lower and upper pedicels exceeding their subtending leaves; main leaves ovate to elliptic, broadest at the rounded to cordate base; capsule mostly exceeding the calyx lobes2. *L. anagallidea*.

1. *Lindernia dubia* (L.) Penn. Plant glabrous, the simple or much-branched stems erect-ascending, to 35 cm. high; leaves narrowly elliptic to oblong or obovate, to 3 cm. long, the lower ones narrowed but the upper ones rounded and clasping at base, entire to remotely dentate; pedicels 5-12 mm. long, stoutish; calyx lobes linear; corolla 7-10 mm. long, those of the later flowers mostly falling unopened; style 2.5-3.5 mm. long; capsule obliquely ellipsoid, about 4 mm. long. Incl. subsp. *major* Penn., *Ilysanthes gratioloides* (L.) DC., *I. dubia* (L.) Barnh. In mud of swamps and stream margins in e. Tex., June-Aug.; from throughout most of U.S., s. to S.A.

2. *Lindernia anagallidea* (Michx.) Penn. Plant glabrous, the slender stems diffusely branched, to about 2 dm. high; leaves ovate to ovate-elliptic, to 2 cm. long, broadest at the rounded or clasping base, the lowermost leaves often slightly narrowed at base, essentially entire; pedicels filiform, to about 25 mm. long; calyx lobes linear; corolla 7-9 mm. long, apparently all opening; capsules 4-5 mm. long. Sandy margins of streams and ponds throughout most of Tex. except the Trans-Pecos, Apr.-Oct.; from throughout most of the U.S., s. to S.A.

11. MICRANTHEMUM MICHX.

Two species in the Western Hemisphere.

1. *Micranthemum umbrosum* (Walt.) Blake. SHADE MUD-FLOWER. Stems repent, freely branched, to 3 dm. long or more; leaves sessile, opposite, succulent, rotund, 4-9 mm. wide; flowers small, white or purplish, solitary in the axils of some of the middle leaves; pedicels to 1 mm. long; calyx 1.5-2 mm. long, equally 4-cleft into oblanceolate lobes; corolla obliquely salverform, barely equaling the calyx, the 4-lobed limb longer than the tube with upper lip developed; appendage of the 2 stamens a mere tooth, the filaments with an appendage; stigmas short; capsule about 1 mm. in diameter, globose, thin, with an evanescent partition, several- to many-seeded. *Globifera umbrosa* (Walt.) J. F. Gmel. On mud or wet sand in low woods and along streams in e. Tex., Apr.-Sept.; from Fla. to Tex., n. to Va.; also trop. Am.

12. VERBASCUM L. MULLEIN

Tall and usually coarse hairy biennial herbs; leaves in radical rosettes and alternate cauline, those of stem sessile and often decurrent; flowers in large terminal spikes, racemes or panicles, ephemeral; calyx deeply 5-parted; corolla 5-lobed, open or concave, with very short tube, the lobes broad and rounded, somewhat asymmetrical; stamens 5, all fertile, with 3 or all of the filaments villous; style flattened at the apex; capsule globular, ovoid to ellipsoid, septicidal, many-seeded.

About 300 species that are native mainly in North Temperate Eurasia.

- 1. Plants tomentose to woolly or scurfy with branching nonglandular hairs; only upper filaments villous with slender yellow hairs; capsule ovoid to ellipsoid, densely tomentose1. *V. Thapsus*.
- 1. Plants glabrous and green or with glandular simple hairs; filaments all villous with violet hairs; capsule subglobose, minutely pubescent to glabrate (2)
- 2(1). Pedicels 10-15 mm. long, longer than calyx; flowers solitary2. *V. Blattaria*.
- 2. Pedicels 3-5 mm. long, shorter than calyx; flowers as many as 5 together3. *V. virgatum*.

1. *Verbascum Thapsus* L. FLANNEL MULLEIN, COMMON MULLEIN. Plant densely grayish- or brownish-woolly throughout; stem erect and stout, simple, to about 2 m. high, winged by the decurrent bases of the leaves; lower leaves petioled, oblong to oblanceolate, to about 3 dm. long, the upper leaves sessile and progressively smaller; flowers in an elongate and very dense cylindrical spike to 5 dm. long; corolla yellow, 1.5-3 cm. broad; lower filaments usually beardless. In fields, on rocky or gravelly banks and in open woodlands throughout most of Tex., Mar.-Nov.; adv. from Eur. in much of N.A.

2. *Verbascum Blattaria* L. MOTH MULLEIN. Plant green, glabrous below and somewhat glandular-pubescent above, to about 1 m. high, the stems slender; lower leaves petioled, oblong, to 25 cm. long, sometimes lyrate, doubly serrate, the upper leaves partly clasping; racemes loose, virgate; pedicels longer than the calyx; sepals linear-elliptic, subacute; corolla 2-3 cm. broad, yellow or white with purplish base [f. *albiflora* (C. Don) House]; filaments all bearded with violet wool. Roadsides and old fields in e. Tex., Mar.-Aug.; from N.E. to Ont., s. to Fla. and Tex.; adv. from Eur.

3. *Verbascum virgatum* Stokes. Similar to *V. Blattaria* but more glandular, early-withering; pedicels 1 to 5 in the axil of each bract, much shorter than the calyx lobes; corolla yellow or whitish. Along roadsides in e. Tex., Mar.-Aug.; from Can. s. to Tex. and westw.; adv. from Eur.

13. LEUCOPHYLLUM H. & B. CENIZO

Low and much-branched shrubs, mostly densely scurfy-tomentose with usually silvery-white branched woolly hairs; leaves alternate, entire, subsessile to shortly petioled; flowers showy, solitary on short bractless pedicels in the leaf axils; calyx 5-cleft; corolla funnelform-campanulate, usually purplish or violet-purple, rarely whitish, the 5 rounded lobes subequal; stamens 4.

More than a dozen species in southwestern United States and Mexico. The species usually flower in response to rainfall.

1. Corolla purple, its throat relatively inflated, 1-1.5 cm. long, only the lower lobes hairy within; anther cells 1.5 mm. long, distally narrowed; leaves elliptic-obovate, closely pubescent, to 25 mm. long, the midrib evident 1. *L. frutescens*.
1. Corolla violet, its throat narrow, less than 1 cm. long, all the lobes somewhat hairy within; anther cells to 1 mm. long, not narrowed distally; leaf blades with obscure midribs (2)
- 2(1). Leaf blades longer than wide, cuneate-spatulate, closely pubescent, usually 7-10 mm. long; corolla lavender-violet, the upper much less hairy than the lower lobes; old branches tending to persist as spines 2. *L. minus*.
2. Leaf blades about as wide as long, obovate-oval, relatively loosely pubescent, 5-18 mm. long; corolla deep violet, all its lobes hirsute; old branches less spinelike ... 3. *L. candidum*.

1. *Leucophyllum frutescens* (Berl.) I. M. Johnst. CENIZO, PURPLE SAGE, TEXAS SILVER-LEAF. Shrub to about 25 dm. high, densely stellate-tomentose throughout; leaves sessile or nearly so, elliptic-obovate, to about 25 mm. long, obtuse to rounded at apex, cuneate at base; calyx lobes oblong-lanceolate; corolla almost campanulate, its limb about 25 mm. wide, delicately soft-villous within. *L. texanum* Benth. Rocky limestone hills, bluffs, ravines, arroyos and brushlands in the Rio Grande Plains and s. Trans-Pecos, throughout the year; also Mex.

2. *Leucophyllum minus* Gray. BIG BEND SILVER-LEAF. Small shrub to about 1 m. high, usually much smaller, finely stellate-tomentose throughout; leaves minutely silvery-canescens, greenish, obovate-spatulate with a long-tapering base, rounded at apex, to 15 mm. long, usually much smaller; calyx-lobes linear; corolla lavender or purplish, 18-25 mm. long, with narrow and funnelform tube and a throat that much-exceeds the limb (about 14 mm. in diameter), sparsely pubescent within. Rocky or gravelly hills, flats and brushlands in the Trans-Pecos; June-Nov.; also N.M. and Mex.

3. *Leucophyllum candidum* I. M. Johnst. Shrub to about 12 dm. high, stiffly and intricately closely branched, the branches leafy to apex, the young growth tomentose-

silvery or faintly yellowish; leaves obovate-oval to nearly orbicular, with obscure midrib, 5-18 mm. long, cuneate to a sessile base; pedicels to 3 mm. long; sepals 3-5 mm. long, lanceolate to ovate, obtuse, in fruit incurved around the capsule; corolla 1-1.8 cm. long, deep-violet, the throat purplish-violet, anteriorly pale and with orange-yellow blotches, externally pubescent, internally hirsute-pubescent on all lobes; anther cells each 0.7-1 mm. long, oblong, rounded, not tapering distally. *L. violaceum* Penn. Rocky or gravelly hills and flat brushlands in Brewster Co., Sept.-Oct.; also Mex.

14. PENSTEMON MITCH.¹⁷⁸ **BEARD-TONGUE**

Herbs or shrubs; leaves opposite, decussate, the lower often petiolate, the upper sessile; pubescence (if present) glandular in the inflorescence, simple below; inflorescence usually a narrow terminal panicle; sepals 5; corolla tubular, the upper lip 2-lobed, the lower lip 3-cleft, the lower inner surface (floor) of the throat and tube often with colored lines; stamens 4; staminode 1, filamentlike, often bearded apically; anthers 2-chambered, these confluent if dehiscent across the connective; capsules septicidal or else 4-valved; seeds many, usually multiangular, with a rough coat. Flowering from spring to fall.

About 300 species; indigenous to America from Alaska to Guatemala.

- 1. Shrubs (2)
- 1. Herbs (3)
- 2(1). Flowers red, campanulate; leaves toothed, oblanceolate to obovate; stem puberulent; inflorescence densely glandular-pubescent; on limestone bluffs 1. *P. baccharifolius*.
- 2. Flowers white or pinkish, salverform; leaves entire, linear; stem and inflorescence glabrous; in sandy soils 2. *P. ambiguus*.
- 3(1). Leaves thick and fleshy, glaucous (4)
- 3. Leaves not thick and fleshy, not glaucous (10)
- 4(3). Flowers red or pink (5)
- 4. Flowers blue or lavender (8)
- 5(4). Orifice of corolla golden-bearded; anther sacs incompletely dehiscent 8. *P. cardinalis* subsp. *regalis*.
- 5. Orifice of corolla glabrous; anther sacs dehiscent throughout (6)
- 6(5). Corolla 14-19 mm. long; staminode pubescent apically 6. *P. Wrightii*.
- 6. Corolla 20-30 mm. long; staminode glabrous (7)
- 7(6). Upper leaves connate-perfoliate; corolla ventricose, the lower lip surpassing or equaling the upper 9. *P. Murrayanus*.
- 7. Upper leaves merely sessile; corolla straight, the upper lip projecting past the lower 7. *P. Havardii*.
- 8(4). Corolla 40-50 mm. long, well-inflated; sepals 7-9 mm. long 10. *P. Bradburii*.
- 8. Corolla 12-20 mm. long; sepals 4-7 mm. long (9)
- 9(8). Leaves and bracts mostly longer than the internodes; inflorescence leafy, the bracts mostly longer than the pedicels 11. *P. Buckleyi*.
- 9. Leaves and bracts shorter than the internodes; inflorescence bare, the bracts mostly shorter than the pedicels 12. *P. Fendleri*.
- 10(3). Corolla red; staminode glabrous (11)
- 10. Corolla blue, white, lavender, rose or pink; staminode hairy (except in *P. dasyphyllus*) (13)

¹⁷⁸ Contributed by Frank S. Crosswhite.

- 11(10). Stem and leaves glabrous; inflorescence glabrous; anther sacs opening from the free ends, remaining saccate at the connective; upper corolla lip projecting past the lower lip 3. *P. barbatus*.
11. Stem and leaves pubescent or puberulent; inflorescence glandular-pubescent; anther sacs not opening from the free ends, not saccate; lower lip up to or exceeding the upper lip (12)
- 12(11). Leaves entire; sepals 5-7 mm. long; anther sacs not peltate-explanate 4. *P. lanceolatus*.
12. Leaves toothed to subentire; sepals 8-9 mm. long; anther sacs peltate-explanate ... 15. *P. triflorus*.
- 13(10). Corolla blue; staminode glabrous; anther sacs twisted, the sutures with long teeth 5. *P. dasyphyllus*.
13. Corolla white, lavender, rose or pink; staminode hairy; anther sacs peltate-explanate or cymbiform, the sutures without long teeth (14)
- 14(13). Seeds 1.5 mm. or less long; herbage glabrous or lightly puberulent (15)
14. Seeds 2-3 mm. long; herbage pubescent or strongly puberulent (18)
- 15(14). Floor of corolla strongly pleated; staminode densely bearded with golden hairs for most of its length, exerted 23. *P. laxiflorus*.
15. Floor of corolla rounded; staminode more lightly bearded with yellow hairs, included (16)
- 16(15). Corolla pink, 15-17 mm. long; leaves regularly sharply but shallowly toothed 20. *P. tenuis*.
16. Corolla white, 16-30 mm. long; leaves subentire or unevenly toothed (17)
- 17(16). Corolla trumpet-shaped, the lobes spreading 22. *P. tubaeflorus*.
17. Corolla ventricose, abruptly expanded, the lobes extending 21. *P. Digitalis*.
- 18(14). Corolla 35-60 mm. long, widely inflated; leaves 25-50 mm. wide 13. *P. Cobaea*.
18. Corolla 10-35 mm. long, bell-shaped or moderately inflated; leaves 2-30 mm. wide (19)
- 19(18). Corolla 10-20 mm. long, bell-shaped (20)
19. Corolla 20-35 mm. long, moderately inflated (21)
- 20(19). Leaves roughly pubescent, resembling fine sandpaper to the touch 19. *P. albidus*.
20. Leaves glabrous or puberulent, not rough to the touch .18. *P. guadalupensis*.
- 21(19). Corolla lavender to purple, 20-30 mm. long; leaves of the midstem 0.2-2 mm. wide (22)
21. Corolla pink or rose, 30-35 mm. long; leaves of the midstem 1.5-3 mm. wide 14. *P. Helli*.
- 22(21). Lower lip of corolla lightly bearded; sepals 5-8 mm. long; leaves of the midstem 2-10 mm. wide 16. *P. brevibarbus*.
22. Lower lip of corolla prominently bearded; sepals about 10 mm. long; leaves of the midstem 9-20 mm. wide 17. *P. Jamesii*.

1. *Penstemon baccharifolius* Hook. Shrub 1.5-4 dm. tall; stem puberulent below, densely glandular-pubescent above and in the inflorescence; leaves of the midstem 5-30 (-40) mm. long, oblanceolate to obovate; corolla scarlet-red, 22-27 mm. long, gradually expanded; sepals densely glandular-pubescent, about 5 mm. long; anther sacs opening from the fixed ends, the free ends remaining somewhat saccate; staminode glabrous; capsules 7-10 mm. long; seeds 1.5-2 mm. long. Limestone bluffs of the Edwards Plateau and Trans-Pecos, June-Sept.; also adj. Mex.

2. *Penstemon ambiguus* Torr. PINK PLAINS PENSTEMON. Shrub 1.5-5 (-15) dm. tall, to 18 dm. in diameter, the stem and leaves minutely pubescent or glabrous; leaves entire, linear, (5-) 10-25 (-40) mm. long, 0.5 mm. wide; inflorescence glabrous; corolla white,

suffused with pink, 17-28 mm. long, the very narrow tube about two thirds the total length of the corolla, the lower lip projecting, the upper lip reflexed, the floor lined with red, the orifice puberulent; sepals 2-3 mm. long; staminode glabrous; capsules 6-8 mm. long; seeds 1 mm. \times 2 mm. Sandy soil in the Trans-Pecos and on the Llano Estacado and Rolling Plains in the Panhandle, May-Aug.; from Colo. to Chih.

3. *Penstemon barbatus* (Cav.) Roth. Plants (2-) 4-7 (-15) dm. tall, the stem and leaves glabrous or very lightly puberulent; leaves entire, those of the stem narrowly lanceolate, 4-8 (-15) cm. long, less than 1 cm. wide; inflorescence glabrous; corolla scarlet-red, 28-32 mm. long, straight or gradually expanded, the upper lip projecting, the lower lip deffected, usually with a few yellow hairs at the orifice, the floor with deep red lines; sepals 5-6 mm. long; anther sacs opening from the free ends, remaining saccate, the dehiscence not proceeding to the connective; staminode glabrous; seeds 1.5-2 mm. long. Throughout the Trans-Pecos, mid-June-Sept.; widespread in cen. Rocky Mts. and Mex.

Typical specimens of *P. barbatus* from Mexico have a prominent golden beard at the corolla orifice. This decreases clinally to the north. Specimens with little or no beard have been referred to var. *Torreyi* (Benth.) Gray (*P. Torreyi* Benth.). Texas specimens are intermediate.

4. *Penstemon lanceolatus* Benth. Plants 2-5.5 dm. tall, the stem and leaves puberulent or pubescent; leaves entire, those of the midstem 25-85 mm. long, 4-8 mm. wide, narrowly lanceolate; inflorescence moderately glandular-pubescent; corolla red, 25-32 mm. long, white-pubescent externally, straight; sepals 5-7 mm. long, glandular, red-margined; staminode glabrous; seeds about 2.5 mm. long. A Mex. species known from the U.S. only in the Chisos Mts., Brewster Co., July.

5. *Penstemon dasyphyllus* Gray. Plants 20-45 cm. tall, the stem and leaves densely white-pubescent; leaves entire or occasionally toothed, those of the midstem to 65 mm. long, 4 mm. wide, narrowly lanceolate to sublinear; inflorescence glandular-pubescent; corolla blue, fading to lavender, 27-35 mm. long, moderately inflated; sepals 5-8 mm. long; staminode glabrous; anther sacs twisted, the sutures with long teeth; seeds about 2 mm. long. Restricted to Brewster Co., Apr.-May; also n. Mex., s. Ariz. and N.M.

6. *Penstemon Wrightii* Hook. Plants (3-) 4-7 (-9) dm. tall, the stem and leaves glabrous; leaves entire, thick and glaucous, those of the midstem (3.5-) 5-7 (-9) cm. long, 1.5-4 (-5) cm. wide; inflorescence glabrous; corolla cerise-red or pink, 14-19 mm. long, gradually expanded to a narrow bell-shape, the floor rounded; sepals 3-5 mm. long; staminode with short retrorse hairs at tip; seeds about 1 mm. in diameter. Mts. of the Trans-Pecos, common in Jeff Davis Co., Apr.-June; endemic.

7. *Penstemon Havardii* Gray. Stems several from a crown, commonly 1-2 m. tall, the stem and leaves glabrous; leaves entire, thick and glaucous, those of the midstem 5-10 cm. long, 2.5-7 cm. wide; inflorescence commonly much-branched; corolla red (drying to yellow), 2-3 cm. long, straight and tubular, the upper lip projecting, the lower lip glabrous; calyx and pedicels lightly glandular-pubescent; anther sacs peltate-explanate; staminode glabrous; seed to 2.5 mm. long when mature, black. Mts. of the Trans-Pecos, common in Brewster Co., Apr.-Oct.; endemic.

8. *Penstemon cardinalis* Woot. & Standl. subsp. *regalis* (A. Nels.) Nisbet & Jackson. Plants mostly 4-6 dm. tall, the stem and leaves glabrous; leaves entire, thick and glaucous, those of the midstem 5-6 cm. long, 4-5 cm. wide, cordate, widely ovate or suborbicular; inflorescence glabrous; corolla scarlet-red, 26-30 mm. long, the upper lip projecting, the lower lip densely bearded with golden hairs; anther sacs opening from the free ends, remaining somewhat saccate, not dehiscing quite to the connective, spinose on the suture; staminode glabrous; capsule eventually prominently 4-valved; seeds 1.5-2.5 mm. long. Endemic to the Guadalupe Mts. of Culberson Co., Tex. and Eddy Co., N.M., May-July.

9. *Penstemon Murrayanus* Hook. Plants 5-10 (-15) dm. tall, the stem and leaves glabrous; leaves entire, thick and glaucous, those of the midstem 5-10 cm. long, 2.5-5 cm. wide, connate-perfoliate above; inflorescence glabrous; corolla bright-red, about 3 cm. long, gradually expanded; sepals 5-7 mm. long; staminode glabrous; capsules 14-18 mm. long, including a beak about 5 mm. long; seeds 3-4 mm. long. Sandy soil throughout e. Tex. and in adj. parts of Okla., Ark. and La., Apr.-May.

10. *Penstemon Bradburii* Pursh. Plants 8-12 dm. tall, the stem and leaves glabrous; leaves entire, thick and glaucous, those of the midstem 3-8 cm. long, 2.5-5 cm. wide;

inflorescence glabrous; corolla lavender, rarely white, 4-5 cm. long, well-inflated; sepals 7-9 mm. long; anther sacs dehiscent throughout but not at all explanate; staminode with short golden hairs at the dilated tip. *P. grandiflorus* Nutt. Sandy soil of the n. Great Plains States, s. to a few scattered stations in Tex., Apr.-May.

11. *Penstemon Buckleyi* Penn. Plants 4-7 dm. tall, the stem and leaves glabrous; leaves entire, thick and glaucous, those of the midstem 3-7 cm. long, 1-3 cm. wide; inflorescence glabrous, the lower bracts large and leaflike, acuminate, varicose with age; corolla lavender, 12-16 mm. long, the floor with lavender lines; sepals 4-5 mm. long, somewhat acuminate; staminode prominently bearded at the tip with short golden hairs; seeds 3-4 mm. long. Sand dunes of the Great Plains, w. Tex., Okla. and w. Kan., Apr.-May.

12. *Penstemon Fendleri* T.&G. Plants commonly 3-4 dm. tall, virgate, the stem and leaves glabrous; leaves entire, thick and glaucous, those just below the inflorescence 2-5 cm. long, 1-3 cm. wide; inflorescence glabrous and usually glaucous, often more than half the height of the plant; corolla 14-20 mm. long, lavender-violet or pink-lavender, often with a prominent concave curvature of the upper surface (especially in bud), the floor white with purplish lines; sepals 4-7 mm. long; anther sacs cymbiform when dehiscent; staminode prominently bearded at the tip with short golden hairs; seeds to 4 mm. long, brown. Calcareous, rocky, sandy soil throughout w. Tex., e. Ariz., N.M., Okla. and w. Kan., Apr.-Aug.

13. *Penstemon Cobaea* Nutt. FOX-GLOVE. Plants commonly 3-6 dm. tall, the stem and leaves pubescent; leaves toothed, petiolate below, sessile at midstem, those of the midstem commonly 5-8.5 cm. long, 2.5-5 cm. wide; inflorescence densely glandular-pubescent; corolla white to pale-lavender, streaked with purple lines, 35-60 mm. long, widely inflated and campanulate, the lower lip glabrous within; sepals densely glandular, commonly 7-12 mm. long; staminode usually included, moderately bearded for most of its length with retrorse yellow hairs; anther sacs dehiscent throughout and usually cymbiform; pollen golden-yellow; seeds 2-3 mm. long. Loamy soil of prairies, common from the Rolling Plains to the Blackland Prairies, s. to the Gulf, May-June; from Neb. to Tex.

14. *Penstemon Helleri* Small. Plants 3-6.5 dm. tall, the stem and young leaves lightly puberulent; leaves well-toothed, those of the midstem (3-) 5.5-9.5 (-11) cm. long, (1.2-) 1.5-3 cm. wide; inflorescence densely glandular-pubescent; corolla light-pink or rose, 30-35 mm. long, campanulate, 12-13 mm. wide when pressed, the floor lined within; sepals (8-) 9-11 mm. long, densely glandular-pubescent; staminode lightly bearded for one-half its length with yellow hairs; seeds about 3 mm. long. *P. triflorus* var. *integrifolius* (Penn.) Cory. Endemic to the Edwards Plateau, Apr.-May.

15. *Penstemon triflorus* Heller. Plants 45-65 cm. tall, the stem and leaves lightly puberulent; leaves subentire to shallowly toothed, those of the midstem 4-7.5 cm. long, 1.2-3 cm. wide; inflorescence moderately glandular-pubescent; corolla red, 25-35 mm. long, glandular within and without, narrowly ventricose, less than 1 cm. wide when pressed, the floor lined within; sepals 8-9 mm. long, densely glandular-pubescent; staminode glabrous; anther sacs peltate-explanate; seeds 3-3.5 mm. long. Endemic to the Edwards Plateau, Apr.-May.

Florally, one of our most brilliant beard-tongues.

16. *Penstemon brevisbarbatus* Crosswhite. Plants 25-55 cm. tall, the stem and leaves puberulent or glabrescent; leaves entire or occasionally toothed, those of the midstem commonly 5-14 cm. long, 2-10 mm. wide, linear to lanceolate; inflorescence glandular-pubescent; corolla lavender, 2-3 cm. long, inflated, the floor with purplish lines, the lower lip very lightly bearded; sepals 5-8 mm. long; staminode lightly bearded for most of its length; seeds about 2.5 mm. long, dark-brown. Endemic to the w. half of the Edwards Plateau and the Trans-Pecos, Apr.-June.

17. *Penstemon Jamesii* Benth. Plants 15-35 cm. tall, the stem and leaves somewhat pubescent; leaves toothed to entire, those of the midstem 5-10 cm. long, 9-20 mm. wide; inflorescence glandular-pubescent; corolla pale-lavender to purple, 20-25 mm. long, inflated, the lower lip prominently bearded within; sepals attenuate, about 1 cm. long; anther sacs dehiscent throughout and finally peltate-explanate; staminode exerted, bearded with yellow hairs for about half its length. On the Llano Estacado in the Panhandle, June; also Ariz., Colo. and N.M.

18. *Penstemon guadalupensis* Heller. Plants 25-35 cm. tall, the stem and leaves puberulent to glabrescent; leaves entire or somewhat toothed, those of the midstem 3-7

cm. long, 2-18 mm. wide, linear to lanceolate; inflorescence glandular-pubescent; corolla white or nearly so, 13-20 mm. long, gradually little-inflated, the floor with purple lines; sepals 5-7 mm. long; anther sacs dehiscent throughout but usually not peltate-explanate; staminode with a few white hairs. Incl. var. *Ernestii* (Penn.) Cory. Endemic to cen. Tex. from the e. Edwards Plateau to the Lampasas Cut Plains, Mar.-May.

19. *Penstemon albidus* Nutt. Plants (1.5-) 3-6 dm. tall, the stem and leaves roughly pubescent (like fine sandpaper to the touch); leaves entire or somewhat toothed, those of the midstem 4-8 cm. long, 8-18 mm. wide, lanceolate; inflorescence densely glandular-pubescent; corolla white to lavender, densely glandular-pubescent within and without, 1-2 cm. long, narrowly funnellform, the lower lip projecting or somewhat deflected, the upper lip reflexed, the floor with prominent purplish lines; sepals densely glandular-pubescent, 5-8 mm. long; anther sacs dehiscent throughout, hippocrepiform and then peltate-explanate; staminode with a few short yellow hairs; capsules 10-15 mm. long; seeds about 3 mm. long. Sandy rocky soil of the Great Plains; in Tex., restricted to the Llano Estacado and Gypsum Plains, Apr.-June.

20. *Penstemon tenuis* Small. Plants 4-9 dm. tall, the stem very lightly puberulent; leaves sharply but shallowly toothed, those of the midstem 7-10 cm. long, 1.5-3 cm. wide, oblong-lanceolate; inflorescence glabrous; corolla pink, 15-17 mm. long, abruptly inflated, the floor rounded, with violet lines; sepals 3-5 mm. long; staminode with yellow hairs on apical half. Uncommon in low poorly drained loamy soils, restricted to the Gulf Prairies and Marshes, Apr.-May; also La. and Ark.

21. *Penstemon Digitalis* Nutt. Plants mostly 5-9 dm. tall, the stem and leaves glabrous; leaves subentire or obviously toothed, those of the midstem mostly 9-12 cm. long, 15-25 mm. wide, lanceolate; inflorescence glabrous or a little glandular; corolla white, 16-30 mm. long, moderately ventricose, the lobes extending, the floor rounded and commonly unlined; sepals 5-6 mm. long, glabrous or a little glandular; staminode lightly bearded with yellow hairs; anther sacs cymbiform, spiny or hairy on the backs; seeds less than 1 mm. long. An Ozarkian species which has been widely spread as a weed in poorly drained soils; occasional in n.e. and e. Tex., Apr.-May.

22. *Penstemon tubaeformis* Nutt. Plant 8-15 dm. tall, the stem and leaves essentially glabrous; leaves entire or somewhat toothed, those of the midstem broadly elliptic to elliptic-lanceolate, obtuse to acute, 7-15 cm. long, 2-4 cm. wide; inflorescence glabrous; corolla white, lightly glandular within and without, 17-23 mm. long, trumpet-shaped, the lips spreading, the floor rounded, without lines; sepals 2-4 mm. long; anther sacs dehiscent throughout, hemispheric; staminode lightly bearded. An Ozarkian species which has spread as a weed elsewhere; sporadic in e. Tex., May-June.

23. *Penstemon laxiflorus* Penn. Plants 3-7 dm. tall, the stem and leaves glabrous to puberulent; leaves well-toothed, those of the midstem 3.2-10.5 cm. long, 4-17 mm. wide, narrowly lanceolate; inflorescence lightly glandular-pubescent; corolla white to pink, 22-30 mm. long, narrow, little-expanded, the floor prominently pleated, lined within; sepals 2-5 mm. long; staminode densely bearded with golden hairs for most of its length, exserted; anther sacs cymbiform; seeds 1-1.5 mm. long. Acid soils of the Gulf Coastal Plain; throughout e. Tex., Mar.-June.

15. SCROPHULARIA L. FIGWORT

About 300 species, mostly in Temperate Zone throughout the world.

1. *Scrophularia marilandica* L. CARPENTER'S SQUARE. Robust perennial herb to about 2 m. high; stem with rounded 4 angles and grooved sides, glabrous; leaves opposite, with slender petioles to 8 cm. long, lanceolate to ovate, acuminate, with strongly rounded to cordate bases, to 25 cm. long and 1 dm. wide, serrate or serrate-dentate; terminal panicle laxly pyramidal to subcylindric, with spreading ascending branches and filiform pedicels; corollas 5-8 mm. long, brown, dull, the tube ventricose and globular or ellipsoid, the 2 upper suborbicular lobes projected forward, the 2 lateral lobes short and rounded with the lowest drooping and reflexed; stamens 4, declined, usually included, the anther cells transverse and confluent into 1; rudimentary stamen brown or purplish, clavate, longer than broad, 1-1.2 mm. long; capsule globose-ovoid, 4-7 mm. long; seeds rugose, margin-

less. On river terraces in rich woods and thickets in n.e. Tex., July-Sept.; from Me. and Que. to Minn., s. to S.C., Ga., Ala., La., Tex. and Okla.

16. COLLINSIA Nutt.

About 20 species, mainly in northwest America.

1. *Collinsia violacea* Nutt. **VIOLET COLLINSIA**. Annual; stems weak, to about 6 dm. high, usually much smaller, glabrous below, often finely glandular-puberulent above; main cauline leaves oblong to lanceolate or elliptic, 1.5-4 cm. long, entire to obscurely serrate, usually widest at or near the middle; flowers parti-colored, 2 to 5 in axillary whorls; calyx lobes 5, ovate-lanceolate, 3-4 mm. long; corolla tube 4-5 mm. long, each lobe cleft to a depth of 2-3 mm., the lower lip violet-color, the upper lip pale-violet to white; fifth stamen glandlike; seeds 6 to 12, 1-1.5 mm. long, the ventral concavity small and inconspicuous. In sandy post oak woods in n.-cen. Tex., Mar.-May; from Mo. to Kan., s. to Tex.

17. LINARIA Mill. TOAD-FLAX

Erect or diffuse annual- or perennial-rooted glabrous herbs; leaves sessile, narrow and scattered; flowers in erect terminal spicate racemes, the bracts short; bracteoles none; sepals 5, distinct; corolla yellow or violet, very irregular, ventrally spurred at base, bilabiate, the lower lip often raised into a palate; stamens 4, didynamous, the glabrous anthers distinct; stigmas united, scarcely capitate; capsule ovoid to cylindrical or globose, rupturing irregularly at the summit; seeds various.

About 150 species in the Northern Hemisphere.

1. Corolla yellow, with prominent orange palate, the stout spur straight or nearly so; capsule longer than wide; seed with wide circular wing; root perennial 1. *L. vulgaris*.
1. Corolla violet or purplish-violet, with a pale palate, the slender spur decurved; capsule as wide as long; seeds cylindrical, prismatic-angled; root annual or biennial (2)
- 2(1). Surfaces and rounded angles of seeds densely tuberculate; corolla over 1 cm. long (excluding spur which is 5-9 mm. long) 2. *L. texana*.
2. Surfaces of seeds smooth or sparsely tuberculate, the angles thin and usually sharp; corolla less than 1 cm. long (excluding spur which is 2-6 mm. long) 3. *L. canadensis*.

1. *Linaria vulgaris* Mill. **BUTTER-AND-EGGS**. Strong-scented perennial spreading by rhizomes, with stems to 1 m. high; leaves numerous, pale-green, linear, to about 5 cm. long and 4 mm. wide; flowers numerous in a compact spike; corolla 1.5-2 cm. long (excluding the spur), its orifice closed by the palate; capsule 9-12 mm. long, rupturing near apex; seeds 1.5 mm. wide, flattened. Rare in n.-cen. Tex., Mar.-Sept.; nat. of Euras. that has become established in various parts of N.A.

2. *Linaria texana* Scheele. **TEXAS TOAD-FLAX**. Annual or winter biennial, the flowering stems erect and to 7 dm. high, with short spreading prostrate branches often produced at base; leaves narrowly linear, rather sparse distally; corolla violet or nearly so, 1-1.4 cm. long (excluding spur); capsule 2.5-3.5 mm. long, rupturing one third to one half its depth; seeds with rounded densely tuberculate angles. *L. canadensis* [var.] *texana* (Scheele) Penn. In sandy soils in fields, open woods and grassy pinelands, mostly in e. two thirds of Tex., rare westw., Feb.-May; from B.C. to Mex., e. to the Atl. Coast.

3. *Linaria canadensis* (L.) Dum. **OLD FIELD TOAD-FLAX**. Annual or winter biennial, the erect flowering stem to 7 dm. high, glabrous, with short spreading prostrate sterile branches often produced at base; leaves narrowly linear, sparse distally, to about 3 cm. long; raceme congested at anthesis, later elongated; corolla violet or nearly so, 8-10 mm. long (excluding spur); capsule 2-3 mm. long, rupturing one third to one half its depth; seeds smooth or sparsely tuberculate and with sharp angles. In sandy-grassy areas in open

woodlands, rare in caliche, in e. third of Tex., Mar.-May; widespread over much of U.S. and s. Can.

18. MAURANDYA ORT.

Diffuse or twining perennial herbs; leaves subopposite to usually scattered or alternate, petiolate; flowers axillary to foliose bracts; bracteoles none; sepals 5, distinct or slightly united at base; corolla bilabiate, ventrally pouched at base, the ventral ridges prominent or united distally into a palate; stamens 4, somewhat didynamous, the anthers tending to adhere and discharge pollen together; stigmas united, small, slightly capitate; capsule globose, rupturing across the distal portion of each cell; seeds irregularly cylindrical, with many longitudinal corky-thickened wing-ridges or lines of tubercles.

About 10 species in the Western Hemisphere.

1. Pedicels 1 cm. or more long; calyx moderately accrescent in fruit, the lower portion not becoming much-thickened or strongly carinate or reticulate; corolla throat partly closed by a large hairy palate; style slender, moderately dilated below; seeds thick, corky-tuberculate; leaves seldom more than 2 cm. long, mostly as wide as or wider than long1. *M. antirrhiniflora*.

1. Pedicels less than 1 cm. long; calyx greatly accrescent in fruit, the lower portion becoming much-thickened, strongly carinate and reticulate; corolla without a palate; style flattened and broadly triangular below; seeds thin, narrowly winged; leaves to 6 cm. long, mostly longer than wide2. *M. Wislizenii*.

1. *Maurandya antirrhiniflora* Willd. SNAPDRAGON VINE. Plant glabrous, the much-branched stems diffuse and extensively twining, the petioles and pedicels also incurved and somewhat flexuous; leaves with petioles 1-3 cm. long, hastate-ovate, 15-25 mm. long and wide, both main blade and lateral lobes acuminate, narrowly cordate at base; pedicels slender, becoming 1-3 cm. long; sepals 1-1.3 cm. long, linear-lanceolate, entire; corolla 2-2.5 cm. long, its tube pale and dull, its lobes violet to purple or rarely whitish, with an upraised yellowish white dark-lined pubescent palate that partly closes the orifice; capsule about 6 mm. long; seeds brown, about 1 mm. long, irregularly corky-winged, the wings broken and some mere lines of tubercles. Climbing over shrubs and boulders and sprawling in dunes, beach areas and dry salt marshes, also limestone hills and on bluffs from the s.-coastal region, through the Rio Grande Plains to the Trans-Pecos, Feb.-Oct.; from Tex. to Calif. s. to s. Mex.

2. *Maurandya Wislizenii* Engelm. Plants glabrous, mostly low-climbing; leaves with petiole 3-5 cm. long, hastate or some of them sagittate, to about 5 cm. long, the lowest ones obtuse, the others acuminate and with pointed basal lobes; pedicels short, stout, less than 1 cm. long; sepals in anthesis linear-lanceolate, becoming in fruit triangular-lanceolate and gradually acuminate, much-enlarged, rather rigid, very veiny-reticulated and strongly saccate-carinate at base to enclose the capsule, about the length of the sword-shaped indurated style; corolla pale-blue, about 25 mm. long, with lips about half the length of the rather ample tube; capsule globose-ovoid, coriaceous; seeds compressed, oval, surrounded by a narrow entire wing, the sides chaffy-rugose. Climbing on shrubs and sprawling over dunes, limestone slopes and in plains in the South Plains and Trans-Pecos, Apr.-July; from Tex. to Ariz. and n. Mex.

19. VERONICASTRUM FABR.

Two species, one in North America, the other in Asia.

1. *Veronicastrum virginicum* (L.) Farw. CULVER'S-ROOT or -PHYSIC. Tall perennial, erect, smooth or minutely pubescent, to about 2 m. high; leaves mostly in whorls of 3 to 7, lanceolate to ovate-lanceolate, acuminate, sharply serrate, glabrous to villous beneath, those of midstem to about 12 cm. long and 3 cm. wide; spikes paniced, terminal, erect, to 15 cm. long, with numerous crowded divergent bracted flowers; calyx deeply 4- or 5-parted; corolla salverform, the tube much longer than the lobes, white or purplish, 7-9 mm. long; stamens and style much-exserted, the 2 stamens inserted low on the tube;

capsule narrowly ovoid, turgid, 4-5 mm. long; seeds numerous, terete, minutely reticulated. *Veronica virginica* L. In rich woodlands in n.e. Tex., June-Sept.; from N.E. to Man., s. to Fla., Miss., La. and Tex.

20. VERONICA L. SPEEDWELL

Erect or repent perennial, biennial or annual herbs; leaves mostly opposite; bracteoles none; flowers in axillary or terminal racemes or solitary in axils of leaves; sepals 4 or 5, distinct; corolla with very short tube, nearly rotate, 4-lobed due to fusion of upper pair; stamens 2; stigmas united and slightly capitate; capsule flattened, loculicidal; seeds flattened, smooth or rarely roughened.

About 300 species, mostly in the North Temperate Zone.

- 1. Flowers in axillary racemes (2)
- 1. Flowers in terminal racemes or solitary in leaf axils (3)
- 2(1). Leaves of flowering stems noticeably petioled; flowers usually less than 30 per raceme; corolla light bluish-violet1. *V. americana*.
- 2. Leaves of flowering stems sessile with at least the upper ones cordate-clasping; flowers usually more than 30 per raceme; corolla lavender and violet2. *V. Anagallis-aquatica*.
- 3(1). Flowers in racemes, essentially sessile, the bracts often passing gradually into the leaves but the uppermost ones usually very different from them (4)
- 3. Flowers distinctly pedicelled, solitary in axils of leaves resembling the cauline leaves but the uppermost ones sometimes smaller (5)
- 4(3). Bracts all much longer than flowers; corolla whitish .3. *V. peregrina*.
- 4. Bracts (at least the upper ones) shorter or scarcely longer than flowers; corolla bluish4. *V. arvensis*.
- 5(3). Lobes of capsule divergent; flowers 8-12 mm. in diameter5. *V. persica*.
- 5. Lobes of capsule not divergent; flowers less than 8 mm. in diameter6. *V. polita*.
